7. Which of the following nursing interventions should be included in the plan of care for a patient at risk for footdrop?
   1. Position the patient in the left lateral position.
   2. Provide daily foot massage.
   3. Apply high-top tennis shoes.
   4. Maintain the patient in an upright position as much as possible.

Answers can be found in Appendix C.

Reference
LEARNING OUTCOMES

1. Explain causes, risk factors, and pathophysiology of central nervous system infections, including meningitis and encephalitis.
2. Plan nursing interventions for a patient with a central nervous system infection.
3. Differentiate between the various types of headaches.
4. Identify teaching you will provide for a patient experiencing headaches.
5. List the causes and types of seizures.
6. Describe appropriate interventions for an individual experiencing a seizure.
7. Recognize a patient who is developing increased intracranial pressure.
8. Identify nursing interventions that can help prevent increased intracranial pressure.
9. Explain the causes, risk factors, and pathophysiology of injuries to the brain and spinal cord.
10. Plan nursing care for a patient with an injury to the brain or spinal cord.
11. Explain causes, risk factors, and pathophysiology associated with neurodegenerative disorders such as Parkinson’s, Huntington’s, and Alzheimer’s diseases.
13. Plan nursing interventions for the patient with dementia.
Disorders of the central nervous system (CNS) include problems originating in the brain and spinal cord. Because the CNS is the control center for the entire body, disorders in this system can cause symptoms in any part of the body, ranging from pain to confusion, paralysis, and coma. This chapter presents nursing care of patients with these disorders. Care of patients with cerebrovascular disorders is covered in Chapter 49.

**CENTRAL NERVOUS SYSTEM INFECTIONS**

Infectious agents can enter the CNS via a variety of routes (Table 48.1). Anything that depresses the patient’s immune system such as steroid administration, chemotherapy, radiation therapy, or malnutrition can make the patient more vulnerable to infection.

**Meningitis**

**Pathophysiology and Etiology**

Meningitis is an inflammation of the meninges that surround the brain and spinal cord. It can be caused by either bacterial or viral infection. Any microorganism that enters the body can result in meningitis. Bacterial meningitis is a serious infection that is spread by direct contact with discharge from the respiratory tract of an infected person. Viral meningitis, also called aseptic meningitis, is more common and rarely serious. It usually presents with flu-like symptoms, and patients recover in 1 to 2 weeks.

The most common bacteria causing meningitis include *Neisseria meningitidis*, *Streptococcus pneumoniae*, and *Haemophilus influenzae* type b (Hib). With current immunization standards in the United States, *H. influenzae* type b has decreased in recent years. *N. meningitidis*, the cause of meningococcal meningitis, and *S. pneumoniae*, the cause of pneumococcal meningitis, are the major causes of bacterial meningitis. Bacterial infection generally begins in another area, such as the upper respiratory tract, enters the blood, and invades the CNS, causing the meninges to become inflamed and intracranial pressure (ICP) to increase. Vessel occlusion and necrosis of areas in the brain can occur. Cranial nerve function can be transiently or permanently affected by meningitis. Some of the effects are listed in Table 48.2.

**Prevention**

Vaccines are available against some pathogens. Hib vaccinations are begun during infancy. A vaccine against *S. pneumoniae* is recommended for people over age 65 and those who have a chronic medical condition. Currently the Centers for Disease Control and Prevention (CDC) recommends 2 doses of meningococcal vaccine (MCV4) for adolescents, one at age 11 or 12 and a booster at age 16. Other groups at increased risk who should be vaccinated are college freshmen living in dormitories, U.S. military recruits, anyone with compromised immunity, laboratory personnel, and those traveling to areas of the world where meningococcal disease is common.

Chemoprophylaxis is recommended for those who have had significant exposure to anyone currently infected with meningitis. To destroy the organism from the nasopharynx, antimicrobials such as rifampin, quinolones, or sulfonamides are used.

**Signs and Symptoms**

The most common symptom of meningitis is a severe headache, caused by tension on blood vessels and irritation of the pain-sensitive dura mater. A high fever and stiff neck are present, and the patient may experience photophobia (light sensitivity). The patient with meningococcal meningitis usually presents with petechiae on the skin and mucous membranes.

**Nuchal rigidity** (pain and stiffness when the neck is moved) is caused by spasm of the extensor muscles of the neck. Positive Kernig’s and Brudzinski’s signs are often seen in patients suffering from meningitis. Both signs are caused by inflammation of the meninges and spinal nerve roots. To elicit Kernig’s sign, the examiner flexes the patient’s hip to

**WORD BUILDING**

- **meningitis**: mening—membranous covering of the brain + itis—inflammation
- **photophobia**: photo—light + phobia—fear or intolerance
90 degrees and tries to extend the patient’s knee. The sign is positive if the patient experiences pain and spasm of the hamstring. Brudzinski’s sign is positive when flexion of the patient’s neck causes the hips and knees to flex (Fig. 48.1). Nausea and vomiting associated with meningitis are caused by direct irritation of brain tissue and by increased ICP.

**Encephalopathy** refers to the mental status changes seen in patients with meningitis. These are manifested as short attention span, poor memory, disorientation, difficulty following commands, and a tendency to misinterpret environmental stimuli. Late signs of meningitis include lethargy and seizures.

**Complications**

Resolution of meningitis depends on how quickly and effectively the disease is treated. Viral meningitis usually has no lasting effects; however, bacterial meningitis can be fatal. Cranial nerve damage can leave the patient blind or deaf. Seizures can continue to occur even after the acute phase of the illness has passed. Cognitive deficits ranging from memory impairment to profound learning disabilities can occur.

**Diagnostic Tests**

A lumbar puncture is the most informative diagnostic test for a patient with suspected meningitis (see Chapter 47). Viral meningitis is characterized by clear cerebrospinal fluid (CSF) with normal glucose level and normal or slightly increased protein level. No bacteria are seen, but the white blood cell (WBC) count is usually increased. In contrast, the CSF of an individual with bacterial meningitis is turbid, or cloudy, because of the elevated number of white blood cells. Bacteria are identified by Gram stain and culture, and a sensitivity test is done to identify the most effective antibiotic. The bacteria use the glucose normally found in CSF, thereby lowering the glucose level. The amount of protein in the CSF is elevated. A magnetic resonance image (MRI) or computed tomographic (CT) scan can be done to evaluate for complications.

**Therapeutic Measures**

Antibiotics such as penicillin G, vancomycin, and cephalosporins are administered for bacterial meningitis. It is important to note the sensitivity report when it is complete to confirm the antibiotic in use is the best choice because there has been an increase in antibiotic/antimicrobial-resistant strains. Symptom management is the same for viral or bacterial meningitis. Antipyretics such as acetaminophen are used to control the fever, a cooling blanket also can be used. Care should be taken to avoid cooling the patient too much because shivering increases the metabolic demand for oxygen and glucose. Analgesics are given to lessen head and neck pain. Corticosteroids and anti-inflammatory agents are given to decrease swelling. Nausea and vomiting are controlled with antiemetic medications. The patient with meningococcal meningitis should be placed in isolation for at least the first 24 hours of medication administration to prevent transmission to others.

Patients can become agitated. A quiet, dark environment lessens the stimulation of a patient who has a headache or photophobia and who is agitated, disoriented, or at risk for seizures. An important aspect of nursing care focuses on keeping patients from harming themselves. It is very upsetting to families to see a loved one acting agitated or disoriented. Therefore, it is important to teach the family about symptoms and treatment goals for the patient (Table 48.3).

**Encephalitis**

**Pathophysiology**

Encephalitis is an inflammation of brain tissue. Nerve cell damage, edema, and necrosis cause neurologic findings localized to the specific areas of the brain affected. Hemorrhage in the brain can occur in some types of encephalitis. Increased ICP can lead to herniation of the brain (see later section on increased ICP).

**Etiology**

Viruses are the most common cause of encephalitis. They can be specifically related to a particular time of year or geographic location. Some viruses, such as West Nile virus, are carried by ticks or mosquitoes. Others are systemic viral infections, such as infectious mononucleosis or mumps, which spread to the brain. Parasites, toxic substances, bacteria, vaccines, and fungi are other potential causes of encephalitis.

Herpes simplex is the most common non–insect-borne virus to cause encephalitis. The majority of individuals harbor herpes simplex virus type 1 in a dormant state. This is the virus responsible for sores on the oral mucous membranes, commonly called cold sores. Communicable diseases, fever, and emotional stress are possible reasons for the virus becoming active, but the exact mechanism is not known.

encephalopathy: encephalo—brain + pathy—illness
encephalitis: encephalo—brain + itis—inflammation

---

*FIGURE 48.1* (A) Kernig’s sign. (B) Brudzinski’s sign.
Signs and Symptoms
As with many viruses, there is a period of headache, general malaise, nausea and vomiting, and fever. These symptoms usually develop over a period of several days. Additional symptoms include nuchal rigidity, confusion, decreased level of consciousness, seizures, photophobia, ataxia (lack of muscle coordination), abnormal sleep patterns, and tremors. The patient may also have hemiparesis (slight paralysis or weakness on one side of the body).

The patient with herpes encephalitis develops edema and necrosis (sometimes associated with hemorrhage), most commonly in the temporal lobes. This significant cerebral edema causes increased ICP and can lead to herniation of the brain. If the patient becomes comatose before treatment is begun, the mortality rate can be as high as 70% to 80%. The first 72 hours is the most likely time for death to occur due to the cerebral edema.

Complications
Patients who have had encephalitis are often left with cognitive disabilities and personality changes. Ongoing seizures, motor deficits, and blindness can also occur. Deterioration in cognition and personality changes are particularly stressful for significant others. The patient’s behavioral control is a major factor in determining discharge plans. You can assist significant others to realistically assess the patient’s functional level and the family’s ability to care for the patient. In-home care, outpatient therapy, and adult day care are options to explore. For some severely impaired individuals, custodial care may be the only feasible and safe discharge option.

Diagnostic Tests
CT scan, MRI, lumbar puncture to obtain CSF, and electroencephalogram (EEG) are used to diagnose encephalitis. CSF analysis typically reveals increased WBC count and protein level and normal glucose levels. Breakdown of blood after cerebral hemorrhage results in yellow-colored CSF. Viral serology can be useful to identify the type of virus and guide treatment options.

Therapeutic Measures
No specific treatment is currently available for insect-borne encephalitis. Careful neurologic assessment and treatment of symptoms can help prevent complications and improve survival. Anticonvulsants, antipyretics, and analgesics are administered to reduce seizures, fever, and headache. Corticosteroids are used to decrease swelling from inflammation. Sedatives may be given for irritability. Antiviral medications such as acyclovir (Zovirax) may also be used, especially for herpes simplex.

### INCREASED INTRACRANIAL PRESSURE

**Pathophysiology and Etiology**
Any patient with a pathological intracranial condition is at risk for increased ICP. ICP is the pressure exerted inside the cranial cavity by its components (blood, brain, and CSF). Normal ICP is 0 to 15 mm Hg. This pressure fluctuates with normal physiological changes, such as arterial pulsations, changes in position, and increases in intrathoracic pressure (e.g., coughing or sneezing). Common causes of increased ICP include brain trauma, intracranial hemorrhage, and brain tumors. Prompt detection of changes in neurologic status indicating increased ICP allows intervention aimed at preventing permanent brain damage.

The skull is a rigid compartment containing three components: brain, blood, and CSF. If an increase in one component is not accompanied by a decrease in one or both of the other components, the result is increased ICP (Fig. 48.2). The consequences of increased ICP depend on the degree of elevation and the speed with which the ICP increases. Patients with slow-growing tumors can have significantly increased ICP before they develop symptoms. Conversely, patients with a subarachnoid hemorrhage can sustain a sudden sharp increase in ICP.

CSF = cerebrospinal fluid; C&S = culture and sensitivity; ICP = intracranial pressure.

**Signs and Symptoms**
As with many viruses, there is a period of headache, general malaise, nausea and vomiting, and fever. These symptoms usually develop over a period of several days. Additional symptoms include nuchal rigidity, confusion, decreased level of consciousness, seizures, photophobia, ataxia (lack of muscle coordination), abnormal sleep patterns, and tremors. The patient may also have hemiparesis (slight paralysis or weakness on one side of the body).

The patient with herpes encephalitis develops edema and necrosis (sometimes associated with hemorrhage), most commonly in the temporal lobes. This significant cerebral edema causes increased ICP and can lead to herniation of the brain. If the patient becomes comatose before treatment is begun, the mortality rate can be as high as 70% to 80%. The first 72 hours is the most likely time for death to occur due to the cerebral edema.

**Complications**
Patients who have had encephalitis are often left with cognitive disabilities and personality changes. Ongoing seizures,
The normally functioning body has several methods of compensating for increased ICP. CSF can be shunted into the spinal subarachnoid space. Hyperventilation can trigger constriction of cerebral blood vessels, decreasing the amount of blood within the cranial vault. These compensatory mechanisms are temporary and not particularly effective if the increase in ICP is sudden or severe.

**Signs and Symptoms**

Initial symptoms of increased ICP include restlessness, irritability, and decreased level of consciousness because cerebral cortex function is impaired. If not intubated, the patient can hyperventilate, causing vasoconstriction as the body attempts to compensate. As the pressure increases, the oculomotor nerve can be compressed on the side of the impairment. Compression of the outermost fibers of the oculomotor nerve results in diminished reactivity and dilation of the pupil. As the fibers become increasingly compressed, the pupil stops reacting to light. If the compression continues and the brain tissue exerts pressure on the opposite side of the brain from the injury, both pupils become fixed and dilated.

Vital sign changes are a late indication of increasing ICP. Cushing’s triad is a classic late sign of increased ICP and is characterized by bradycardia, irregular respirations, and arterial hypertension (increasing systolic blood pressure while diastolic blood pressure remains the same), resulting in widening pulse pressure. By the time these symptoms appear the ICP is significantly increased and interventions may not be successful.

**Monitoring**

ICP monitoring allows for early detection of changes in the pressure on the brain, before changes in symptoms are seen. The most common method of monitoring ICP in adults is by placing a catheter in one of the lateral ventricles and drilling a hole, called a burr hole, into the skull.

Placement of a catheter into one of the lateral ventricles is referred to as external ventricular drainage (Fig. 48.3). This method allows for pressure monitoring as well as drainage of CSF to reduce ICP. Disadvantages to this method include difficulty in locating the ventricle for insertion of the catheter and clotting of the catheter by blood in the CSF.

To allow communication with the subarachnoid space, a subarachnoid bolt can be tightly screwed into the burr hole after the dura has been punctured (Fig. 48.4). The advantage of a subarachnoid bolt is ease of placement. Disadvantages include occlusion of the sensor portion of the bolt with brain tissue and inability to drain CSF. An intraparenchymal monitor is placed directly into brain tissue. Some physicians believe that this most accurately reflects the actual situation within the skull. These monitors cannot be used to drain CSF and can become occluded by brain tissue.

Patients with ICP monitors are cared for in an intensive care unit (ICU) and require aggressive nursing care to prevent complications. These patients are often mechanically ventilated and may be pharmacologically paralyzed and sedated. In addition to meeting the patient’s physiological needs and preventing complications, education and emotional support for significant others is important.

**Nursing Process for the Patient With a Communicable or Inflammatory Neurologic Disorder**

**Data Collection**

Collaborate with the registered nurse (RN) to obtain a complete history from the patient, if feasible, and from significant others. Pay particular attention to exposure to risk factors. The physical examination must include all body systems because neurologic impairment affects the entire person. Following the initial examination, serial neurologic assessments continue to be important to detect and report changes promptly. You can assist with monitoring pupil response, level of consciousness (LOC), and vital signs for signs of increased ICP (Box 48-1). Monitor headache on a pain scale if the patient is able to participate. The Glasgow Coma Scale...
or the FOUR Score, presented in Chapter 47, are valuable tools to monitor level of consciousness.

**Nursing Diagnoses, Planning, and Implementation**

The licensed practical nurse/licensed vocational nurse (LPN/LVN) collaborates with the RN in implementing care. For additional interventions for patients with communicable or inflammatory disorders, see the “Nursing Care Plan for the Patient With a Brain Tumor or Injury.”

**Patient Education**

The nature and focus of teaching depend on the patient’s level of consciousness and cognitive status. When appropriate, both the patient and significant others should be included in the education process. If the patient is not able to participate, the significant others become the focus of teaching.

**NURSING CARE PLAN for the Patient With a Brain Lesion or Injury**

**Nursing Diagnosis:** Hyperthermia related to infectious process

**Expected Outcome:** The patient will not exhibit evidence of hyperthermia.

**Evaluation of Outcome:** Is temperature controlled?

**Intervention** Assess temperature every 4 hours and as needed (prn). **Rationale** An elevated temperature can increase risk for seizures. **Evaluation** Is temperature controlled?
NURSING CARE PLAN for the Patient With a Brain Lesion or Injury—cont’d

Intervention Administer acetaminophen or aspirin as ordered. Rationale Antipyretic agents reduce fever.
Evaluation Are antipyretics effective?

Intervention Provide a cooling mattress or tepid sponge baths as necessary. Rationale A cooling mattress may be necessary to reduce fever. These are uncomfortable for the patient. Comfort can be increased and shivering reduced by cooling the patient gradually and wrapping extremities in bath blankets during cooling mattress therapy. Evaluation Is cooling mattress or tepid bath effective? Is patient comfort maintained?

Nursing Diagnosis: Risk for Acute Confusion related to cerebral edema and increased intracranial pressure

Expected Outcomes: The patient will be oriented to person, place, and time; if this is not possible, patient’s safety will be maintained.

Evaluation of Outcomes: Is patient oriented to self, place, and time and able to ask for help appropriately to prevent injury?

Intervention Assess level of consciousness (LOC) using Glasgow Coma Scale or the FOUR Score. Rationale Change in LOC can indicate increased intracranial pressure and should be reported. Evaluation Is patient alert and responsive? Is LOC stable?

Intervention Monitor orientation and reorient as needed. Rationale Giving correct information to patient will assist in orientation. Evaluation Can patient identify who he/she is, location, and month, year, or season?

Intervention Observe patient’s reaction to simple commands such as “raise your hand.” Rationale This helps distinguish between reflexes and purposeful movement. Evaluation Is patient able to follow simple commands?

Intervention Monitor patient’s capabilities as activities increase. Rationale Patient can experience dizziness, imbalance, and confusion; the patient will need assistance with mobilization until stable. Evaluation Can patient sit up and ambulate to chair without dizziness?

Intervention If patient is not able to be reoriented, assess for safety and implement appropriate safety measures. Rationale Depending on the patient’s prognosis, orientation may not be a realistic goal. Evaluation Is patient’s safety maintained?

Nursing Diagnosis: Self-Care Deficit, dressing/feeding/toileting, related to mental status changes and inability to perform ADLs independently

Expected Outcome: The patient will maintain as much independence with ADLs as possible.

Evaluation of Outcome: Is the patient able to participate in self-care at an appropriate level?

Intervention Assess what the patient was able to do before admission/injury. Rationale The patient’s potential for participation will depend on what he or she was able to do before injury. Evaluation What was the patient able to do? How does that compare with what he or she can do now?

Intervention Provide all supplies and equipment needed to carry out ADLs. Rationale Assembling equipment for the patient reserves energy for performing self-care. Evaluation Is the patient able to perform the majority of bath and hygiene tasks with appropriate setup?

Intervention Encourage the patient to perform activities at own pace. Rationale The patient may need more time to perform activities. Evaluation Does the patient gradually increase performance of self-care in a timely fashion?
**NURSING CARE PLAN** for the Patient With a Brain Lesion or Injury—cont’d

**Intervention** Teach and encourage family to participate with care. **Rationale** Including the family in the patient’s care promotes support and family interaction. **Evaluation** Is the family involved? Is the patient accepting of their assistance?

**Intervention** Refer to occupational therapy if indicated. **Rationale** An occupational therapist is trained to assist patients to manage ADLs within health limitations. **Evaluation** Is occupational therapist able to assist patient with strategies to maintain independence?

**Nursing Diagnosis:** *Acute/Chronic Pain* related to cerebral edema and headache as evidenced by patient pain rating or evidence of painful behaviors

**Expected Outcomes:** Patient’s pain is controlled as evidenced by statement that pain level is acceptable, or decrease in painful behaviors.

**Evaluation of Outcomes:** Does patient state pain level is acceptable? Are pain behaviors reduced?

**Intervention** Assess pain using a scale of 0 to 10 or PAINAD scale (see Chapter 10). **Rationale** The patient’s self-report is the best measure of the patient’s pain. **Evaluation** Is the patient able to rate pain? Is there evidence that pain is present?

**Intervention** Monitor vital signs. **Rationale** Pulse and blood pressure can be elevated in acute pain. **Evaluation** Are vital signs elevated?

**Intervention** Administer appropriate pain medication as ordered. **Rationale** Nonnarcotic medications are preferred because they do not alter the level of consciousness. If these are not effective, codeine preparations, which have a minimal effect on LOC, may be prescribed. **Evaluation** Does patient state pain has decreased? Is sedation minimized?

**Intervention** Implement measures to reduce ICP. See Table 48.4 for measures and rationales. **Rationale** Increased intracranial pressure can increase pain. **Evaluation** Do measures to reduce ICP help prevent pain?

**Intervention** Provide alternative comfort measures such as dim lights, a quiet environment, and positioning for comfort. **Rationale** Decreasing stimuli in the room by dimming lights and decreasing noise can have a calming effect. **Evaluation** Is patient resting quietly, with no evidence of pain?

**Nursing Diagnosis:** *Risk for Injury Secondary to Impaired Sensory Perception* related to brain injury and cranial nerve involvement as evidenced by alterations in response to stimuli

**Expected Outcome:** The patient will be kept safe from injury related to reduced sensation.

**Evaluation of Outcome:** Is patient safe? Is skin intact?

**Intervention** Monitor patient’s ability to perceive stimuli. **Rationale** Changes in patient’s perceptions must be incorporated into the plan of care. **Evaluation** What can the patient feel?

**Intervention** Turn patient and assess skin at least every 2 hours while in bed; provide moisturizer as needed. Protect bony prominences. **Rationale** If the patient cannot determine pressure or dryness, the nurse must evaluate and act to prevent skin breakdown. **Evaluation** Is skin intact, pink, warm, dry, and without redness?

**Intervention** Assist the patient out of bed and into a different environment. **Rationale** This can help prevent sensory deprivation and social isolation. **Evaluation** How does patient respond to being in a chair or wheelchair and taken to sunroom or common area?
### Intervention
Teach the patient to monitor own position and skin, and to direct position changes. **Rationale** This provides a way for the patient to maintain some control over his body and to take part in preventing complications. **Evaluation** Is patient able to direct care activities effectively?

### Nursing Diagnosis: Impaired Physical Mobility related to motor deficits as evidenced by weakness, inability to change position

### Expected Outcomes: The patient will maintain maximum mobility and be free from complications of immobility.

### Evaluation of Outcomes: Is patient kept mobile without contractures? Is skin intact?

### Intervention
Assess degree of mobility limitation. **Rationale** A good assessment can help determine how much the patient can actively participate in a plan for mobilization. **Evaluation** How much can patient do independently? Is physical/occupational therapy evaluation indicated?

### Intervention
Turn patient every 1 to 2 hours; if postoperative, avoid positioning on the operative site unless specifically permitted by the surgeon. **Rationale** Turning helps prevent skin and respiratory complications. **Evaluation** Is a turning schedule maintained? Is skin free from redness and breakdown?

### Intervention
Position patient in correct body alignment. High-top tennis shoes, trochanter rolls, and slings can be used to keep the body in alignment. **Rationale** This keeps the patient in functional position in case function is regained in the future. **Evaluation** Are all joints maintained in correct alignment?

### Intervention
Perform range-of-motion (ROM) exercises; consult physical therapy as ordered. **Rationale** ROM exercises help prevent contractures. **Evaluation** If patient unable to perform active ROM exercises, are passive ROM exercises provided on a regular schedule?

### Intervention
Consult occupational therapist to assist the patient in learning to perform ADLs. **Rationale** The patient may be able to participate in self-care with assistive devices. **Evaluation** Do assistive devices help patient mobilize and maintain independence?

### Nursing Diagnosis: Risk for Injury related to seizures

### Expected Outcome: The patient will remain free of injury if a seizure occurs.

### Evaluation of Outcome: Is safety maintained? Is skin intact, without bruising or discoloration?

### Intervention
Observe the patient’s behavior and time the length of the seizure. When patient is alert following seizure, determine if an aura occurred, and what it was. **Rationale** Observing the seizure can provide clues for teaching the patient to recognize the warning signs of a future seizure and how to maintain safety. **Evaluation** What did the patient experience? What can be taught to help keep patient safe in the future?

### Intervention
If patient loses consciousness during the seizure, lay patient on his or her side or turn head to the side. **Rationale** This helps prevent oral secretions from being aspirated. **Evaluation** Did patient maintain a patent airway without respiratory distress?

### Intervention
Remove objects from patient’s surroundings to prevent injury during a seizure. If the patient must have side rails, pad them with blankets or foam (see also Table 48.6, later in chapter). **Rationale** During a tonic-clonic seizure the patient can be harmed by hitting furniture or other objects. **Evaluation** Is patient protected from objects that could cause injury during a seizure?
TABLE 48.4 MEASURES TO PREVENT INCREASED INTRACRANIAL PRESSURE

<table>

ICP = intracranial pressure.

Describing the brain as in control of body functions can help significant others to understand some of the symptoms of neurologic disorders. The spinal cord can be compared to a telephone cord, with hundreds of tiny individual wires (nerves) making up the cord. The specific wires affected by disease determine the symptoms the patient experiences.

CRITICAL THINKING

Mr. Chung

Mr. Chung is an 18-year-old Asian college student. He comes to the emergency department with a headache, stiff neck, and fever. On physical assessment, you notice a petechial rash on his legs and torso. The physician diagnoses meningococcal meningitis.

1. What tests are likely to be performed?
2. What patient education should be planned for Mr. Chung?
3. What infection control practices should be instituted?
4. What comfort measures might you offer to Mr. Chung?
5. What concerns do you have about how Mr. Chung contracted his illness?

Suggested answers are at the end of the chapter.

HEADACHES

As mentioned throughout this chapter, headache is a common symptom of neurologic disorders. However, most headaches are transient events and do not indicate a serious pathological condition. If headaches are recurrent, persistent, or increasing in severity, the patient should undergo a neurologic evaluation. This section addresses the most common types of headache.

Types of Headaches

Headaches are divided into three major types: (1) primary, (2) secondary, and (3) cranial neuralgias, central and primary facial pain and other headaches. Primary headaches are discussed in this section. Secondary headaches are caused by trauma, infection, or other disorders. Cranial neuralgias are discussed in Chapter 50. For more information visit the International Headache Society at http://ihs-classification.org/en. Because the causes, signs and symptoms, pathophysiology, and treatment of headaches vary based on the type of headache experienced, these subjects are discussed separately for each type of headache.

Migraine Headaches

One long-held theory is that a migraine headache is caused by cerebral vasoconstriction followed by vasodilation. The vasoconstriction can be due to a response triggered by the trigeminal nerve, which stimulates release of substance P, a pain transmitter, into the vessels or by the release of amines such as serotonin, norepinephrine, and epinephrine. A migraine may or may not begin with an aura (visual phenomena, such as a flashing light that precedes an attack). The tendency to develop migraine headaches is often hereditary; they frequently begin in childhood or adolescence and are more common in women. Commonly used descriptors of migraine pain include throbbing, boring, vise-like, and pounding. The pain is usually on one side of the head. Noise and light tend to worsen the headache, leading patients to seek a dark, quiet environment. Triggers
 episodes. Alcohol consumption may worsen the time span of several days to weeks. Months or even years can follow after an episode. The headache tends to be unilateral, affecting the nose, eye, and forehead. A bloodshot, teary appearance of the affected eye is common.

Because of the brief nature of cluster headaches, treatment is difficult. A quiet, dark environment and cold compresses can lessen the intensity of the pain. NSAIDs or tricyclic antidepressants may be prescribed.

## Diagnosis of Headaches

Most headaches are diagnosed based on the patient’s history and symptoms. MRI, CT, skull x-ray, arteriogram, EEG, cranial nerve testing, and lumbar puncture to test CSF may be done to rule out other causes for the headaches.

### Nursing Process for the Patient With a Headache

#### Data Collection

The **WHAT'S UP?** mnemonic is particularly useful in helping the patient provide useful information regarding the headache:

- **W**—Where is the pain? Does it remain in one place or radiate to other areas of the head? Does the headache consistently start in one place?
- **H**—How does the headache feel? Is it throbbing, steady, dull, bandlike, or does it have other qualities?
- **A**—Aggravating or alleviating factors should be assessed. Some aggravating factors include red wine, caffeine, chocolate, and foods containing nitrates or monosodium glutamate (MSG). Other factors include particular stages of the menstrual cycle, emotional stress, and tension. Alleviating factors might include lying down in a dark room, cold compresses, or medications.
- **T**—Timing can be a factor for a patient who experiences headaches just before or during her menstrual period. For other patients, there may be no predictive timing. Also ask how long the headache lasted.
- **S**—Ask the patient to rate the severity on a scale of 0 to 10. Is the severity consistent or does it vary from headache to headache?
- **U**—Ask about other useful data. For example, are there associated symptoms, such as nausea, vomiting, or bloodshot eyes?
- **P**—Determine the patient’s perception of the headache. Does it interfere with the patient’s life? If so, how? Has the patient had a previous evaluation of headaches?

### Tension or Muscle Contraction Headaches

Persistent contraction of the scalp and facial, cervical, and upper thoracic muscles can cause tension headaches. A cycle of muscle tension, muscle tenderness, and further muscle tension is established. This cycle may or may not be associated with vasodilation of cerebral arteries. Headaches of this type can be associated with premenstrual syndrome or psychosocial stressors such as anxiety, emotional distress, or depression. Symptoms typically develop gradually. Radiation of pain to the crown of the head and base of the skull, with variations in location and intensity, is common. **Pressure, aching, steady, and tight** are some of the words patients use to describe the pain of tension headaches.

Care must be taken to thoroughly rule out physical causes before attributing the headache to psychosocial origins. Symptom management may include the use of relaxation techniques, massage of the affected muscles, rest, localized heat application, nonopioid analgesics, and appropriate counseling.

### Cluster Headaches

Vascular disturbance, stress, anxiety, and emotional distress are all proposed causes of cluster headaches. As indicated by the name, these headaches tend to occur in clusters during a time span of several days to weeks. Months or even years can pass between episodes. Alcohol consumption may worsen the episodes.
Chapter 48  Nursing Care of Patients With Central Nervous System Disorders

Nursing Diagnoses, Planning, and Implementation

Acute Pain (Headache) related to lack of knowledge of pain prevention and control techniques as evidenced by patient’s pain rating

Expected Outcome: Headache will be prevented or controlled as evidenced by patient statement of no pain or acceptable pain rating.

- Assist the patient to identify and reduce or eliminate aggravating factors. This can be accomplished by keeping a headache diary for a time, recording the time of day the headache occurs, foods eaten or other aggravating factors, description of the pain, identification of associated symptoms such as nausea or visual disturbances, and other factors related to headache symptoms. Identification of triggers can help the patient lessen the frequency and intensity of attacks.
- Encourage the patient to use alleviating techniques such as biofeedback or stress reduction. This helps the patient participate in the treatment of the headache and provides a sense of control over his or her illness.
- Teach the patient to use relaxation exercises and warm or cool moist compresses. These interventions may be helpful for tension headaches.
- Provide a dark room and rest to reduce stimulation during a migraine headache.
- Teach the patient about medications, appropriate dosage, expected action, side effects, and consequences of misuse. The patient will need to understand medication administration for appropriate use at home.

Evaluation

If interventions have been effective, the patient will understand self-care to prevent and treat headaches and be able to report a reduction in headache pain and occurrences.

SEIZURE DISORDERS

Seizures/Epilepsy

A seizure can be a symptom of epilepsy or of other neurologic disorders such as a brain tumor or meningitis. Epilepsy is a chronic neurologic disorder characterized by recurrent seizure activity.

Pathophysiology

The normal stability of the neuron cell membrane is impaired in individuals with epilepsy. This instability allows for abnormal electrical discharges to occur. These discharges cause the characteristic symptoms seen during a seizure.

Seizures can be classified as partial or generalized. Partial seizures begin on one side of the cerebral cortex. In some cases, the electrical discharge spreads to the other hemisphere and the seizure becomes generalized. Generalized seizures are characterized by involvement of both cerebral hemispheres.

Etiology

Epilepsy can be acquired or idiopathic (unknown cause). Causes of acquired epilepsy include traumatic brain injury and anoxic events. No cause has been identified for idiopathic epilepsy. The most common time for idiopathic epilepsy to begin is before age 20. New-onset seizures after this age are most commonly caused by an underlying neurologic disorder. As the population ages, more older adults are having first-time seizures as a result of bleeding or bruising in the brain related to a fall. Multiple medications in the elderly population and untreated hypertension can increase the risk of falls, as well as brain injury after a fall.

Signs and Symptoms

Symptoms of seizure activity correlate with the area of the brain where the seizure begins. Some patients experience an aura or sensation that warns that a seizure is about to occur. An aura can be a visual distortion, a noxious odor, or an unusual sound. Patients who experience an aura may have enough time to sit or lie down before the seizure starts, thereby minimizing the risk of injury.

PARTIAL SEIZURES. Repetitive, purposeless behaviors, called automatisms, are the classic symptom of partial seizures. The patient appears to be in a dreamlike state while picking at his or her clothing, chewing, or smacking his or her lips. Patients may be labeled as mentally ill, particularly if automatisms include unacceptable social behaviors such as spitting or fondling themselves. Patients are not aware of their behavior or that it is inappropriate. If the patient does not lose consciousness, the seizure is labeled as simple partial and usually lasts less than 1 minute. Older terms for simple partial seizures include Jacksonian and focal motor. If consciousness is lost, it is called a complex partial seizure or psychomotor seizure, and can last from 2 to 15 minutes.

Partial seizures arising from the parietal lobe can cause paresthesias on the side of the body opposite the seizure focus. Visual disturbances are seen if the seizure originates in the occipital lobe. Involvement of the motor cortex results in involuntary movements of the opposite side of the body. Typically, movements begin in the arm and hand and can spread to the leg and face.

The postictal period is the recovery period after a seizure. Following a partial seizure, the postictal phase may be no more than a few minutes of disorientation.

GENERALIZED SEIZURES. Generalized seizures affect the entire brain. Two types of generalized seizures are absence seizures and tonic-clonic seizures. Absence seizures, sometimes referred to as petit mal seizures, occur most often in children and are manifested by a period of staring that lasts several seconds.

Tonic-clonic seizures are what most people envision when they think of seizures; they are sometimes called grand mal...
seizures or convulsions. Tonic-clonic seizures follow a typical progression. Aura and loss of consciousness may or may not occur. The tonic phase, lasting 30 to 60 seconds, is characterized by rigidity, causing the patient to fall if not lying down. The pupils are fixed and dilated, the hands and jaws are clenched, and the patient can temporarily stop breathing. The clonic phase is signaled by contraction and relaxation of all muscles in a jerky, rhythmic fashion. The extremities can move forcefully, causing injury if the patient strikes furniture or walls. The patient is often incontinent. Biting the lips or tongue can cause bleeding.

The postictal period is usually longer after a tonic-clonic seizure. Patients may sleep deeply for 30 minutes to several hours. Following this deep sleep, patients may report headache, confusion, and fatigue. Patients may realize that they had a seizure but not remember the event itself.

**Diagnostic Tests**

An EEG is the most useful test for evaluating seizures. An EEG can determine where in the brain the seizures start, the frequency and duration of seizures, and the presence of subclinical (asymptomatic) seizures. Sleep deprivation and flashing light stimulation may be used to evaluate the seizure threshold. See Chapter 47 for more information on EEGs.

**Therapeutic Measures**

If an underlying cause for the seizure is identified, treatment focuses on correcting the cause. If no cause is found or if the seizures continue despite treatment of concurrent disorders, treatment focuses on stopping or preventing the seizure activity.

Numerous anticonvulsant medications are available, each with specific actions, therapeutic ranges, and potential side effects (Table 48.5). Typically, the patient is started on one drug, and the dosage is increased until therapeutic levels are attained or side effects become troublesome. If seizures are not controlled on a single drug, another medication is added. Many anticonvulsants require periodic blood tests to monitor serum levels as well as kidney and liver functions. Most of these medications can cause drowsiness, so teach the patient to avoid driving or operating machinery until the effects of the drug are known. Driving is also contraindicated until seizures are under control.

If a patient must discontinue an anticonvulsant, it should be tapered slowly according to manufacturer directions. Stopping an anticonvulsant abruptly can result in status epilepticus, discussed later. If seizures continue despite anticonvulsant therapy, surgical intervention may be considered.

**Emergency Agents**

Potentiate GABA, an inhibitory neurotransmitter in the CNS. lorazepam (Ativan) diazepam (Valium, Diastat) Given to stop a seizure that has not resolved within 5 minutes. Given IM or IV push by emergency personnel. Rectal Diastat may be given at home.

---

Note. RBC = red blood cell; SR = sustained release; WBC = white blood cell.
Surgical Management

The success of surgical intervention for epilepsy depends on identification of an epileptic focus within nonvital brain tissue. The surgeon attempts to resect the area affected to prevent spread of seizure activity. In some cases, seizures can be cured, but in others, the goal is to reduce the frequency or severity of the seizures. If no focus is identified or if it is in a vital area such as the motor cortex or speech center, surgery is not feasible.

The preoperative assessment for epilepsy surgery is an extensive multistage process. Thorough assessment and teaching are essential. To adequately identify seizure foci, the patient is weaned off anticonvulsant therapy. Increasing the frequency of seizures with weaning is anxiety provoking for patients and significant others.

Emergency Care

Emergency care is required when a seizure occurs. The prime objective is to prevent injury during a seizure. Side rails, if used, should be padded to prevent injury if the patient strikes his or her extremities against them. If the patient falls to the floor, move furniture out of the way. Maintain a patent airway and, if possible, turn the patient on his or her side to prevent aspiration if vomiting occurs. Do not force an airway or anything else into the patient’s mouth once the seizure has begun. Do not restrain the individual because this can also increase the risk of injury. Observe and document the patient’s behavior during the seizure: which part of the body was first involved, progression of the seizure, and the length of time the seizure lasted (see “Patient Perspective”). After the seizure, assess the patient for breathing, suction if necessary, and, in rare cases, initiate rescue breathing or cardiopulmonary resuscitation (CPR) as indicated.

Patient Perspective

Mrs. Rowley

I have had seizures for 35 years and, as a result of falling during seizures, have experienced cuts, bruises, and a broken bone. I usually have an aura that lets me know a seizure is about to occur. This is helpful if I can get myself to a safe place to prevent falling or being injured. When a patient is having a seizure you can best help by using padding such as pillows or blankets for protection, talking calmly, and using gentle touch to prevent injury. You should not sit on or hold down someone during a seizure. I have had the frightening experience of waking up with a nurse sitting on me and holding down my arms. After you have protected the patient, let the person come out of the seizure naturally. When the seizure is over, I usually want to sleep because seizures are exhausting.

Status Epilepticus

Status epilepticus is characterized by at least 30 minutes of repetitive seizure activity without a return to consciousness. This is a medical emergency and requires prompt intervention to prevent irreversible neurologic damage. A abrupt cessation of anticonvulsant therapy is the usual cause of status epilepticus. Seizure activity precipitates a significant increase in the brain’s need for glucose and oxygen. This metabolic demand is even greater during status epilepticus. Irreversible neuronal damage can occur if cerebral metabolic needs cannot be fulfilled. Adequate oxygenation must be maintained, if necessary, by intubating and mechanically ventilating the patient. These patients are also at significant risk for aspiration. Therefore, it is important that the nurse assist in airway maintenance and suction as needed to prevent hypoxia and aspiration pneumonia.

Intravenous (IV) diazepam (Valium) or lorazepam (Ativan) is given to stop active seizures. Diazepam can also be given rectally. Because both of these drugs can cause respiratory depression, careful airway management is required. After obtaining serum drug levels, anticonvulsant therapy is adjusted to achieve therapeutic levels.

If seizures remain resistant to treatment, a barbiturate coma may be induced with IV pentobarbital. The last line of treatment for status epilepticus is general anesthesia or pharmacological paralysis. Both of these therapies require intubation, mechanical ventilation, and management in an ICU setting. Continuous EEG monitoring is used to verify that the seizures have actually stopped. A patient treated with neuromuscular blockade drugs can still be seizing but have no visible manifestations.

For more information on seizures, visit the Epilepsy Foundation of America at www.efa.org.

Psychosocial Effects

Finances can be a major concern to patients with seizure disorders. Some patients with epilepsy experience hiring discrimination, or they may not qualify for some jobs in which safety is a concern. Remind patients that falsifying information on job applications may be grounds for dismissal. Refusal of health insurance coverage can create financial hardships for patients on long-term medications. Most patients whose seizures are controlled can work and lead productive lives. A social worker can help explore options for financial assistance if needed.

Patients with poorly controlled seizures should not operate motor vehicles. In today’s society, a driver’s license is a sign of adulthood and independence, and patients who cannot drive can experience lowered self-esteem. Job opportunities may be limited for patients who depend on public transportation. Encourage the patient to obtain a state identification card. This can be used in place of a driver’s license for identification.

Patients may limit interpersonal relationships out of fear of having a seizure. The involuntary movements, sounds, and possible incontinence that occur with seizures are embarrassing to patients and can be frightening to laypeople.
Role-playing may help the patient determine when and how to confide in others.

**Nursing Process for the Patient With Seizures**

**Data Collection**

Perform a general neurologic examination of the patient with a history of seizures. Determine the type of seizure manifestations and type of aura if any. Assess the patient’s knowledge of the disease and its treatment. It is important to assess whether the patient has the resources to purchase prescribed anticonvulsant medications and whether the medication regimen is adhered to. Drug levels can help determine degree of adherence to therapy.

**Nursing Diagnoses, Planning, and Implementation**

**Risk for Injury related to seizure activity**

**Expected Outcome:** The patient will remain free from injury.

- Instruct the patient with generalized seizures to recognize an aura and to get to safety if it occurs. This may mean lying down away from furniture or other objects. This helps prevent injury during involuntary movements.
- Institute seizure precautions for the patient admitted to a health care institution. See Table 48.6 for precautions and interventions to prevent injury.
- Encourage all patients to wear medical alert jewelry or other identification to alert others to the presence of seizure disorder.
- Assist patients to identify conditions that trigger seizures. Hypoglycemia, hypoxia, and hyponatremia are all potential triggers of hypersensitive neurons. Teach the patient the importance of a consistent schedule of eating and sleeping. The patient may be able to prevent seizures by avoidance of triggers.

**Risk for Ineffective Self Health Management related to complex regimen and possible lack of resources**

**Expected Outcome:** The patient will follow medication regimen as evidenced by therapeutic drug levels and controlled seizure activity.

- Assess patient’s ability to obtain and pay for medication. Stopping a medication suddenly can result in status epilepticus.
- Refer patient to a case manager or social worker, if needed, to assist with obtaining resources for medications.
- Teach the patient about medication action, dose, side effects, schedule, and the importance of not stopping treatment suddenly. Patients with seizures can have several medications to take several times each day. Patients who understand their regimens are more likely to comply.
- Teach the patient about the importance of regular blood tests if required. Therapeutic blood levels help prevent seizures (too low) and toxicity (too high).

**Evaluation**

Successful care of a patient with epilepsy is manifested by a decrease in seizures to the lowest possible frequency. Patient verbalization of understanding of needed lifestyle changes is another indication of success. Patients should be able to state measures to prevent injury if a seizure should occur and should verbalize understanding of all medications and their administration schedules. Therapeutic drug levels can be measured to evaluate adherence to the medication regimen.

### Traumatic Brain Injury

Traumatic brain injury is a major cause of death and disability in adults. Young men make up a large proportion of brain injury victims.

**Pathophysiology**

Traumatic brain injury is a complex phenomenon with results ranging from no detectable effect to a persistent vegetative state. Trauma can result in hemorrhage, contusion or laceration of the brain, and damage at the cellular level. In addition to the primary insult, the brain injury can be compounded by cerebral edema, hyperemia, or hydrocephalus.

**Etiology**

Motor vehicle accidents account for the largest percentage of traumatic brain injuries. Falls, sports-related injuries, and violence are also common causes of traumatic brain injury.

The brain is susceptible to various types of injury that can be classified in several ways. The term closed head injury or nonpenetrating injury is used when there has been rapid back and forth movement of the brain that causes bruising and tearing of brain tissues and vessels, but the skull is intact. An open head injury or penetrating injury refers to a break in the skull. Acceleration injury is the term used to describe a moving object hitting a stationary head. An example of this type

</tbody>
</table>
of injury is a patient who is hit in the head with a baseball bat. A decceleration injury occurs when the head is in motion and strikes a stationary surface. This type of injury is seen in patients who trip and fall, hitting their head on furniture or the floor.

A combination of acceleration-deceleration injury occurs when the stationary head is hit by a mobile object and the head then strikes a stationary surface. A soccer player who sustains a blow to the head and then hits the ground with his or her head can sustain an acceleration-deceleration injury.

Rotational injuries have the potential to cause shearing damage to the brain, as well as lacerations and contusions. Rotational injuries can be caused by a direct blow to the head or can occur during a motor vehicle accident in which the vehicle is struck from the side. Twisting of the brainstem can damage the reticular activating system, causing loss of consciousness. Movement of the brain within the skull can result in bruising or tearing of brain tissue where it comes in contact with the inside of the skull.

Types of Brain Injury and Signs and Symptoms

Concussion
Cerebral concussion is considered a mild brain injury. If there is a loss of consciousness, it is for 5 minutes or less. Concussion is characterized by headache, dizziness, or nausea and vomiting. The patient may describe amnesia of events before or after the trauma. On clinical examination, there is no skull or dura injury and no abnormality detected on CT or MRI.

Confusion
Cerebral contusion is characterized by bruising of brain tissue, possibly accompanied by hemorrhage. There can be multiple areas of contusion, depending on the causative mechanism. Severe contusions can result in diffuse axonal injury. The symptoms of a cerebral contusion depend on the area of the brain involved.

Brainstem contusions affect level of consciousness. Decreased level of consciousness can be transient or permanent. Respirations, pupil reaction, eye movement, and motor response to stimuli can also be affected. The autonomic nervous system can be affected by edema or by hypothalamic injury, causing rapid heart rate and respiratory rate, fever, and diaphoresis.

Hematoma

**SUBDURAL HEMATOMA.** Subdural hematomas are classified as acute or chronic based on the time interval between injury and onset of symptoms. Acute subdural hematoma is characterized by appearance of symptoms within 24 hours following injury. The bleeding is typically venous in nature and accumulates between the dura and arachnoid membranes (Fig. 48.5). About 24% of patients who sustain a severe brain injury develop an acute subdural hematoma. Damage to the brain tissue can cause an altered level of consciousness. Therefore, it can be difficult to recognize a subdural hematoma on the basis of clinical examination alone. As the subdural hematoma increases in size, the patient may exhibit one-sided paralysis of extraocular movement, extremity weakness, or dilation of the pupil. Level of consciousness can deteriorate further as ICP increases.

Older adults and people with alcoholism are particularly prone to chronic subdural hematomas. Atrophy of the brain, common in these populations, stretches the veins between the brain and the dura. A seemingly minor fall or blow to the head can cause these stretched veins to rupture and bleed. Often there are no other injuries associated with the trauma. Because a chronic subdural hematoma can develop weeks to months after the injury, the patient may not remember an injury occurring.

The patient with a chronic subdural hematoma may be forgetful, lethargic, or irritable or may report a headache. If the hematoma persists or increases in size, the patient can develop hemiparesis and pupillary changes. The patient or significant other may not associate the symptoms with a previous injury and therefore may delay seeking medical care.

**EPIDURAL HEMATOMA.** About 10% of patients with severe brain injuries develop epidural hematomas. This collection of blood between the dura mater and skull is usually arterial in nature and is often associated with skull fracture (see Fig. 48.5). Arterial bleeding can cause the hematoma to become large very quickly. Patients with epidural hematoma typically exhibit a progressive course of symptoms. The patient loses consciousness directly after the injury; he or she then regains consciousness and is coherent for a brief period. The patient then develops a dilated pupil and paralyzed extraocular muscles on the side of the hematoma and becomes less responsive. If there is no intervention, the patient becomes unresponsive. Seizures or hemiparesis can occur. Once the
patient has symptoms, the deterioration can be rapid. Airway management and control of ICP must be instituted immediately. If ICP is not controlled, the patient will die.

**Diagnostic Tests**

CT scan is usually the first imaging test performed on a patient with a brain injury. It is faster and more accessible than MRI. This is particularly important for unstable patients or those with multiple injuries. It is easier to identify skull fractures on CT than on MRI. MRI can be used later to identify damage to the brain tissue.

Neuropsychological testing by a trained specialist can be useful in assessing the patient’s cognitive function. This information helps direct rehabilitation placement, discharge planning, and return to work or school. Neuropsychological testing identifies problems with memory, judgment, learning, and comprehension. Patients may be able to learn compensation strategies based on the results.

**Therapeutic Measures**

**Surgical Management**

Surgical treatment of hematomas is discussed under intracranial surgery later in this chapter.

**Medical Management**

Medical management of traumatic brain injury involves control of ICP and support of body functions. Patients with brain injuries can be partially or completely dependent for maintenance of respiration, nutrition, elimination, movement, and skin integrity.

A variety of techniques are used to control ICP in the patient with moderate or severe brain injury. The first step is to insert an ICP monitor to allow measurement of the ICP. Refer to the section on increased ICP earlier in this chapter for further information.

If ICP remains elevated despite drainage of CSF, the next step is use of an osmotic diuretic. The most commonly used drug is IV mannitol (Osmitrol). Mannitol uses osmosis to pull fluid from the brain into the intravascular space and eliminate it via the renal system. Serum osmolarity and electrolytes must be carefully monitored when mannitol is being administered. Some patients experience a rebound increase in ICP after the mannitol wears off.

Mechanical hyperventilation may be used if the patient is still experiencing increased ICP. Hyperventilation is effective in lowering ICP because it causes cerebral vasoconstriction. Vasoconstriction allows less blood into the cranium, thereby lowering ICP. Research has demonstrated, however, that aggressive hyperventilation, particularly within the first 24 hours after injury, can induce ischemia in the already compromised brain. Therefore, hyperventilation is now reserved for increased ICP that does not respond to other treatments.

High-dose barbiturate therapy may be used to induce a therapeutic coma, which reduces the metabolic needs of the brain during the acute phase following injury. These patients are completely dependent for all of their needs and care. They will be mechanically ventilated and cared for in an ICU setting. Vasopressors may be required to maintain blood pressure, and the patient’s temperature should be kept as normal as possible.

**Complications**

**Brain Herniation**

If interventions to control ICP are unsuccessful, the patient can experience uncontrolled edema or herniation of brain tissue (Fig. 48.6). Herniation is displacement of brain tissue out of its normal anatomical location. This displacement prevents function of the herniated tissue and places pressure on other vital structures, most commonly the brainstem. Herniation usually results in brain death.

Patients who experience brain death may be suitable organ donor candidates. For some significant others, the opportunity to donate their loved one’s organs provides some sense of purpose in the death (Table 48.7).

**Diabetes Insipidus**

Edema or direct injury that affects the posterior portion of the pituitary gland or hypothalamus can result in inadequate release of antidiuretic hormone, causing diabetes insipidus.

![Herniation of brain tissue into tentorial notch](image-url)
This results in polyuria and, if the patient is awake, polydipsia. Fluid replacement and IV vasopressin are used to maintain fluid and electrolyte balance. See Chapter 39 for more information on diabetes insipidus.

**Acute Hydrocephalus**

Cerebral edema can interfere with cerebrospinal fluid circulation, causing hydrocephalus. Initial treatment is use of an external ventricular drain, followed by a ventriculoperitoneal shunt if necessary. A shunt drains excess CSF into the peritoneum, where it is reabsorbed into circulation and excreted.

**Labile Vital Signs**

Direct trauma to or pressure on the brainstem can cause fluctuations in blood pressure, cardiac rhythm, or respiratory pattern. Treatment is aimed at control of ICP.

**Post-Traumatic Stress Disorder**

Patients who sustain a concussion can experience ongoing, somewhat vague symptoms. They may report headache, fatigue, difficulty concentrating, depression, or memory impairment. Symptoms can be severe enough to interfere with work, school, and interpersonal relationships. Neuropsychological testing can provide objective evidence of cognitive dysfunction and establish the need for cognitive rehabilitation for posttraumatic stress disorder, or PTSD (see Chapter 57 for more about PTSD). Symptoms can take 3 to 12 months to resolve.

**Cognitive and Personality Changes**

Alterations in personality and cognition may be the most difficult long-term complication for patients and significant others to adjust to. The patient can have significant short-term memory impairment. This limits his or her ability to learn new information and can interfere with ability to function at work or school. Impaired judgment can make the patient a safety risk to self or others. It also affects social functioning.

Emotional lability, loss of social inhibitions, and personality changes may occur. These consequences of traumatic brain injury have a profound effect on the patient and significant others. Spouses may state, “This is not the person I married.” If behavior is violent, bizarre, or profane, children may be unwilling to bring their friends home and can become socially isolated. Young children, in particular, have difficulty understanding why a parent is behaving so differently. Disintegration of relationships is not uncommon following traumatic brain injury.

Neuropsychological testing objectively identifies problems. These deficits can then be addressed with cognitive rehabilitation. Individual and family counseling can be of benefit. Support groups for patients and significant others are often helpful.

Motor and speech impairment are additional possible long-term complications of traumatic brain injury. Intensive rehabilitation provides the best opportunity for maximizing recovery. For more information, visit the Brain Injury Association at www.biausa.org.

**Nursing Process for the Patient With Traumatic Brain Injury**

Acute care is presented here. Also see the “Nursing Care Plan for the Patient With a Brain Tumor or Injury.”

**Data Collection**

After stabilization in the emergency department, care of the patient with a severe traumatic brain injury is in the

This results in polyuria and, if the patient is awake, polydipsia. Fluid replacement and IV vasopressin are used to maintain fluid and electrolyte balance. See Chapter 39 for more information on diabetes insipidus.

**hydrocephalus:** hydro—water + cephalus—head
intensive care setting, where ICP can be carefully monitored. Frequent data collection is essential, including a Glasgow Coma Scale score or the FOUR Score (see Chapter 47), pupil responses, muscle strength, and vital signs. Review Box 48-1, “Signs and Symptoms of Increased Intracranial Pressure,” for additional signs of increased ICP for which to monitor. Once the patient is stabilized, neurologic damage is assessed. Identification of deficits guides nursing care. Assessment of discharge needs should begin as soon as possible. The patient may require extensive rehabilitation, and early referral can speed transfer to an appropriate facility.

**Nursing Diagnoses, Planning, and Implementation**

**Risk for Ineffective Cerebral Tissue Perfusion related to increased ICP**

**EXPECTED OUTCOME:** Changes in cerebral tissue perfusion will be prevented or recognized and reported promptly.

- Monitor vital signs for widening pulse pressure or irregular respirations. These are signs of increased ICP and should be reported promptly.

- Monitor Glasgow Coma Scale or FOUR Score and report worsening status promptly. Decreasing level of consciousness (LOC) can indicate increased ICP and may necessitate emergency intervention.

- Implement measures to prevent increased ICP. See Table 48.4 for preventive measures and rationale.

**Ineffective Airway Clearance related to reduced cough reflex and decreased level of consciousness as evidenced by adventitious lung sounds and dropping Spo2**

**EXPECTED OUTCOME:** The patient will maintain a clear airway as evidenced by clear breath sounds and Spo2 of 90% or above.

- Monitor airway and breath sounds. If the patient has excess secretions and is unable to cough effectively, suctioning may be necessary.

- Limit suction passes to one or two at a time for a maximum of 5 to 10 seconds each time. Suctioning can increase ICP.

- Keep head of bed elevated 20 to 30 degrees to reduce risk of aspirating oral secretions and reduce ICP.

- Turn the patient frequently to help mobilize secretions and prevent other complications of immobility.

**Risk for Ineffective Breathing Pattern related to pressure on respiratory center**

**EXPECTED OUTCOME:** The patient will maintain Spo2 of 90% or above.

- Monitor respiratory rate and depth, arterial blood gases (ABGs), and Spo2 and report changes. If respiratory status is deteriorating, mechanical ventilation may be necessary.

- Elevate head of bed 20 to 30 degrees to allow chest expansion and ease work of breathing.

- Administer oxygen as ordered and needed to prevent hypoxia. Hypoxia promotes brain death.

---

**Evaluation**

The plan of care has been successful if the patient shows no unexpected worsening of neurologic function and injuries and complications are prevented. The patient’s airway should be clear and Spo2 level should be 90% or above. The patient is kept comfortable, and self-care needs are met.

**Rehabilitation**

Once the patient is stabilized, evaluation for discharge to a rehabilitation facility is completed. The patient must be able to physically tolerate the rehabilitation program, in which the patient will be taught to function as independently as possible. The family must be prepared for changes in the patient’s ability to function and possible changes in personality. It can take months to years before the patient reaches his or her maximum potential. In some cases of severe brain damage or continued comatose state, rehabilitation is not feasible and the patient is discharged to home or a long-term facility for custodial care.

---

**CRITICAL THINKING**

Mr. Evans

Mr. Evans is a 24-year-old white male who was involved in a motor vehicle crash. His blood alcohol level was 0.24. Mr. Evans has no preexisting medical problems. Emergency medical services personnel report that Mr. Evans was unconscious on their arrival at the scene and then became alert and combative. His CT scan shows a left-sided epidural hematoma. Mr. Evans is admitted to your unit for observation.

1. What symptoms would you expect to see if Mr. Evans’ hematoma increases in size?
2. What emergency preparations should you have ready?
3. What psychosocial data should you collect?
4. What other members of the health team should be consulted?

*Suggested answers are at the end of the chapter.*

---

**BRAIN TUMORS**

Brain tumors are neoplastic growths of the brain or meninges. Brain tumors can be characterized by vague symptoms such as headache or visual changes or by focal neurologic deficits such as hemiparesis or seizures.

**Pathophysiology and Etiology**

Brain tumors cause symptoms by either compressing or infiltrating brain tissue. Tumors can arise from CNS cells or can metastasize from other locations in the body. Primary brain tumors rarely metastasize; however, if they do, it is to the spine.
There is no established cause for primary brain tumors. It is unclear what causes the cells to begin reproducing in an uncontrolled fashion. Risk factors include age (45 and older), exposure to radiation or industrial chemicals, and family history. Whites are more likely to be diagnosed with a brain tumor than other racial or ethnic groups.

Brain tumors can be classified in several ways. The traditional distinction of benign and malignant is less helpful when classifying brain tumors than when classifying other cancers. A benign tumor in the brainstem can be fatal, whereas a malignant tumor in the frontal lobe may not be. Location of the tumor can be just as important a factor in outcome as the cell type.

Primary tumors are those arising from cells of the CNS. Intra-axial tumors are those that arise from the glial cells within the cerebrum, cerebellum, or brainstem. These tumors infiltrate and invade brain tissue. Extra-axial tumors arise from the skull, meninges, pituitary gland, or cranial nerves; they place pressure on the brain.

Most brain tumors are secondary; that is, they have metastasized from a primary malignancy somewhere else in the body (Fig. 48.7). These tumors commonly spread via the arterial system. If untreated, they cause increased ICP. This can be the cause of the patient’s death rather than the primary malignancy.

**Signs and Symptoms**

The symptoms of a brain tumor are directly related to the location of the tumor in the brain and to the rate of growth. Slow-growing types of tumors such as meningiomas (a tumor arising from the meninges; Fig. 48.8) can get to be quite large before causing symptoms. Conversely, glioblastoma multiforme or metastatic tumors can abruptly cause seizures or hemiparesis. Other types of tumors include oligodendroglioma, astrocytoma, and acoustic neuroma. The suffix -oma refers to tumor. The prefix denotes the type of cell from which the tumor arises.

The most common early symptom of a brain tumor is fatigue. Other symptoms depend on tumor size and location and can include seizures, motor and sensory deficits, nausea and vomiting, headaches, personality changes, confusion, and speech and vision disturbances. If the pituitary gland is involved, additional symptoms related to changes in hormone secretion occur, such as abnormal growth or fluid volume imbalances.

**Diagnostic Tests**

MRI gives the clearest images of a brain tumor. If the tumor appears to be highly vascular or in proximity to major blood vessels, an angiogram may be performed. It is now possible to do a magnetic resonance angiogram, which involves the IV administration of contrast material and is much less invasive than a traditional angiogram. If the tumor is in the region of the pituitary gland, serum hormone levels are evaluated. Biopsy may be done during surgical removal of the tumor, or using needle aspiration. Additional tests may be carried out to find a primary cancer site.

**Therapeutic Measures**

**Surgery**

Surgical treatment involves removal of the tumor or as much of the tumor as possible. Care of the patient under going intracranial surgery is discussed later in this chapter.

**Medical Treatment**

Medical treatment is aimed at controlling symptoms. Patients who have a seizure are placed on anticonvulsants. If significant cerebral edema is noted on the MRI or if the patient is suffering from headaches or other symptoms, a steroid such
as dexamethasone (Decadron) may be prescribed to lessen the edema and reduce symptoms. Typically, patients do not require narcotics for pain relief.

**Radiation Therapy**

External beam radiation therapy is standard treatment for many patients with a brain tumor. The therapy is typically given 5 days a week for 6 weeks. Some clinicians use a hyperfractionated schedule, in which the patient has therapy twice a day for less time. Brachytherapy is a means of delivering radiation therapy directly to the tumor. Small catheters are implanted in the tumor, and then tiny radioactive particles are inserted into the catheters. The treatment typically takes 3 to 5 days. During this time the patient is confined to a private room and interaction with visitors and staff is kept to a minimum because of the radioactivity. This therapy is not appropriate for confused individuals because they may not be able to cooperate with restrictions.

Stereotactic radiosurgery is a technique that uses small amounts of radiation directed at the tumor from different angles. A metal frame is affixed to the patient’s skull, and the tumor is visualized within the framework on a CT or MRI. A computer plan is generated to direct the radiation. Because multiple small sources are used, the normal brain tissue receives very little radiation, while the majority of the radiation accumulates in the tumor.

**Chemotherapy**

The blood–brain barrier is a protective mechanism that prevents many injurious substances from reaching brain tissue. Unfortunately, it is also effective in preventing most chemotherapy agents from reaching the brain. To penetrate the blood–brain barrier, large doses of chemotherapy may be required. These doses may not be well tolerated by other body systems. New treatments are currently being investigated. Some clinicians place chemotherapy substances in the cavity left by surgical resection. Others disrupt the blood–brain barrier with mannitol (an osmotic diuretic) and then deliver intra-arterial chemotherapy under general anesthesia. Another newer treatment, called targeted drug therapy, uses a drug such as bevacizumab (Avastin), which stops formation of new blood vessels that support the tumor. Gene therapy is also being used in an effort to kill malignant cells.

**Complementary and Alternative Therapies**

The primary purpose of intracranial surgery is to remove a mass lesion. These types of lesions include hematomas, tumors, arteriovenous malformations, and, occasionally, confused brain tissue. Other indications for surgery include elevation of a depressed skull fracture, removal of a foreign body, debridement of a wound, or resection of a seizure focus. The term **craniotomy** refers to any surgical opening in the skull. A burr hole is an opening into the cranium made with a drill. **Cranietomy** is the term used to describe removal of part of the cranial bone. **Cranioplasty** refers to repair of bone or use of a prosthesis to replace bone following surgery.

The goal of intracranial surgery is gross total resection of the tumor. This involves removal of all visible tumor, called **debulking**. Even with the use of an operative microscope, viable tumor cells can be left behind that can give rise to recurrence. If the entire tumor cannot be removed, the surgeon debunks as much as possible, thereby giving radiation therapy or chemotherapy less of a burden to combat. In some cases, it is not feasible to attempt more than a biopsy of the tumor. Location of the tumor or the patient’s age or medical condition may not allow the patient to tolerate a full craniotomy. The biopsy may be done under local or general anesthesia, depending on the patient’s condition. The goal of a biopsy is to obtain tissue that allows pathological diagnosis of the tumor, which then guides any further treatment.

**Additional information on evaluation of complementary and alternative therapies is found in Chapter 5.**

**Acute and Long-Term Complications**

It is difficult to distinguish between symptoms of a brain tumor and complications of treatment. Seizures, headaches, memory impairment, cognitive changes, and ataxia can be symptoms of the tumor or the result of sur gery or radiation therapy. Patients can experience hemiparesis or aphasia following surgery. If the tumor continues to grow despite treatment, the patient will experience further decline in function. Gradually the patient becomes more lethargic and unresponsive. Once the patient becomes comatose, death occurs within a matter of days, particularly if artificial nutrition and hydration are not administered.

**Nursing Process for the Patient With a Brain Tumor**

Nursing care of the patient with a brain tumor is similar to that for the patient with a brain injury because both experience neurologic deficits. See the “Nursing Care Plan for the Patient With a Brain Lesion or Injury.”

**Word Building**

- **craniotomy**: crani—skull + otomy—incision
- **craniectomy**: crani—skull + ectomy—excision, removal
- **cranioplasty**: crani—skull + plasty—to form
Intracranial surgery is usually performed under general anesthesia. Occasionally, a procedure requires that the patient be awake and cooperative.

Preoperative Care

Preoperative care of the patient undergoing intracranial surgery is similar to that of patients having other surgeries (see Chapter 12). The patient undergoes a laboratory workup and anesthesia evaluation. If the patient has cognitive impairments, it is important that a significant other be available to provide information and sign consents. A thorough baseline neurologic assessment should be documented.

Patient education is important preoperatively. The extent of education depends on the patient’s ability to absorb new information, which is influenced by the disease process, cognitive functioning, anxiety, and educational level. Significant others are involved as needed. Information about the disease process and surgery is provided by the surgeon. The nurse can play an important role in reinforcing and clarifying the information presented.

Anxiety is also a significant concern before surgery. The patient is anticipating serious surgery, as well as an unknown outcome. Allow time for the patient and significant others to express their fears and ask questions. Honest and accurate information should be provided.

Significant others should be prepared for how the patient will look after surgery. A preoperative visit to the intensive care unit may help prevent some anxiety postoperatively. Significant others should be accompanied on this visit by a knowledgeable nurse who can explain what they are seeing.

Surgery can last 2 hours for a biopsy to 12 hours or longer for more involved procedures. Patients and significant others should be prepared for the idea that some or all of the patient’s hair will be shaved off. Some people prefer to have all their hair shaved rather than just part. The patient should be prepared to see his or her face swollen after surgery, particularly around the eyes; the periorbital region may be bruised. Many patients wish to wear a scarf or scrub cap after the dressing is removed.

Nursing Process for the Postoperative Care of the Patient Having Intracranial Surgery

Acute care of the postoperative patient is presented here. Also see the “Nursing Care Plan for the Patient With a Brain Tumor or Injury.”

Data Collection

After intracranial surgery, the patient will be cared for in an ICU. Plan to assist the RN with frequent neurologic assessments in addition to routine postoperative monitoring. Patients should have their neurologic status assessed every hour for the first 24 hours or as ordered by the health care provider (HCP). Many patients undergo a CT scan within the first 24 hours following surgery to assess cerebral edema. Also assess the patient’s response to changes in body image and the patient’s knowledge base related to care that will be required following discharge.

Nursing Diagnoses, Planning, and Implementation

The primary goal after intracranial surgery is prevention of complications. Once the patient is stabilized, goals can change to longer-term outcomes such as acceptance of changes in body image and understanding of self-care following discharge. If the patient has severe deficits following surgery, rehabilitation or long-term care may become necessary. A consultation with a social worker can help with planning for this transition. Priority nursing diagnoses are discussed next.

Risk for Ineffective Cerebral Tissue Perfusion related to edema of the operative site

**EXPECTED OUTCOME:** The patient will have adequate cerebral tissue perfusion as evidenced by stable or improving neurologic assessments.

- Monitor neurologic status as ordered. Report changes promptly. Deteriorating status can signify increased ICP.
- Implement measures to prevent increased ICP. See Table 48.4 for preventive measures and rationales.
- Position patient with the head of the bed at 30 degrees or higher, unless ordered otherwise, to promote venous drainage and minimize increases in ICP. The exception to this is patients who have had a chronic subdural hematoma removed, these patients must remain flat.
-Patients can turn from side to side or lie on their back but should not lie on the operative side.
- Implement seizure precautions because the patient is at risk for seizures due to cerebral edema.
- Use caution to protect the many monitoring systems being used. The patient may have an intracranial monitor in place following surgery to monitor ICP.
  - Some patients may also have central venous pressure catheters or pulmonary artery catheters to monitor fluid status. Urinary catheters are used during the immediate postoperative period to accurately monitor fluid balance.
- Monitor dressings for drainage. Drainage that is blood tinged in the center with a yellowish ring around it can be CSF leakage. A suspected CSF leak should be reported to the RN or physician immediately.
- Monitor patient for rise in temperature, purulence at incision site, and increase in white cell count. These are signs of infection and should be reported immediately.
- Use strict aseptic technique for all care of the incision, dressing, and monitoring equipment sites to reduce risk of infection.
- Use appropriate hand hygiene to reduce risk of transmitting infection.
Disturbed Body Image related to changes in appearance or function as evidenced by patient statement of disturbance or unwillingness to observe changes

**EXPECTED OUTCOME:** The patient will display an accepting attitude toward change in appearance, as evidenced by willingness to look in mirror and/or be seen by others.

- Offer a turban, scarf, or hat if the patient desires to help conceal a shaved head.
- Portray an accepting attitude toward the patient. *Patients are likely aware of nurses’ nonverbal behavior.*
- Allow the patient to express his or her feelings if desired. *Talking may help the patient work through feelings, but it should not be forced.*

Deficient Knowledge related to change in treatment regimen after surgery as evidenced by patient statement

**EXPECTED OUTCOME:** The patient and significant others will verbalize correct information for follow-up care at home. They will state they have the resources to manage care effectively.

- Teach the patient and family or significant other home management, including medication regimen, wound care, and ordered activity restrictions, including driving. Have the patient and significant others verbalize the signs of infection or other possible complications to report. *The patient and family will assume responsibility for care after discharge, unless the patient is being transferred to another facility.*
- Teach patient and family seizure precautions and the importance of taking anticonvulsants as ordered. *The patient may be on anticonvulsants to prevent seizures after surgery. If seizure free for 1 year, the physician may discontinue anticonvulsants.*
- Consult social worker or case manager for resources if needed. *The patient may need discharge planning if transfer to another facility is planned. If discharge home is expected, the patient and family will benefit from visiting nurse follow-up. Assistance with obtaining medications can also be provided if necessary.*

**Evaluation**

Interventions have been effective if the patient’s neurologic status is stable and infection and other complications have been prevented. The patient might be able to look in the mirror and begin to show evidence of acceptance of changes in body image, although this may not happen until after discharge from the hospital. The patient or significant others should be able to demonstrate appropriate follow-up care.

---

**SPINAL DISORDERS**

**Herniated Disks**

Herniated intravertebral disks are a common health problem. They are characterized by pain and paresthesias that follow a radicular (nerve path) pattern. It is not uncommon for patients to have more than one herniated disk or to have herniated disks in different areas of the spine.

**Pathophysiology**

When the disk between two vertebrae herniates, it moves out of its normal anatomical position. In most cases, the annulus fibrosus, the tough outer ring of the disk, tears. This allows escape of the nucleus pulposus, the soft inner portion of the disk. Displacement of the disk compresses one or more nerve roots, causing the characteristic symptoms (Fig. 48.9).

**Etiology**

In some cases, a specific event can be correlated with a herniated disk. The patient may describe a fall, lifting a heavy object, or a motor vehicle accident. In other instances, the patient cannot identify a triggering incident.

**Signs and Symptoms**

Cervical disk herniation causes pain and muscle spasm in the neck. The patient may have decreased range of motion secondary to pain. Hand and arm pain is unilateral (one sided) and follows the distribution of the spinal nerve root. Patients often report numbness or tingling in the extremity. Asymmetrical weakness and atrophy of specific muscle groups may be detected. If weakness involves the entire extremity, it is unlikely that disk herniation is the etiology. The severity of the pain or paresthesia does not correlate directly with the severity of the nerve compression. However, weakness and atrophy are indicators of significant nerve compression.

Thoracic herniated disks are not common. This portion of the spine is the least mobile; therefore, less stress is exerted on the disks. Patients with herniated thoracic disks may report pain in the back. It is uncommon to detect muscular weakness.

A herniated lumbar disk is typically characterized by low back pain, pain radiating down one leg, paresthesias, and weakness. The patient may limp on the affected leg or may have difficulty walking on his or her heels or toes. Muscle...
Chapter 48  Nursing Care of Patients With Central Nervous System Disorders  1141

spasm is often present. Pain and muscle spasm can limit the patient’s range of motion. Depending on the disk affected, the knee or ankle deep tendon reflex may be decreased or absent. A severely herniated L5–S1 disk can affect bowel or bladder continence. This is an emergency situation and should be reported immediately.

The WHAT’S UP? mnemonic can be used to assess symptoms of herniated disks at any level:

W—Where is the pain? Does it radiate into an extremity?
   In what distribution?
H—How does it feel? Sharp, stabbing, burning?
A—Do certain positions or activities alleviate or aggravate the pain? Holding the affected arm above the head can alleviate cervical pain. Sitting places pressure on disks and aggravates lumbar pain. Lying down may relieve it.
T—Is there a correlation between time and pain? Some patients have more pain at the end of the day. Is the pain constant or intermittent?
S—Ask the patient to rate the severity of the pain on a scale of 0 to 10. Which is the most painful, the spine or the extremity?
U—Ask the patient to identify other useful data, such as symptoms of numbness, tingling, or weakness.
P—What is the patient’s perception of the pain? Is it interfering with work or other aspects of the patient’s life?

Diagnostic Tests
An MRI will detect herniation of a disk and compression or abnormality of the spinal cord. If the patient has previously had surgery in the area of the suspected herniation, the MRI is done with and without contrast to differentiate between scar tissue and a herniated disk.

If the patient cannot tolerate an MRI or if the MRI does not provide enough information, a myelogram can be done. Refer to Appendix A for a description of both tests.

Therapeutic Measures
Most HCPs and patients prefer to try conservative medical therapy before performing surgery for a herniated disk.

MEDICAL TREATMENT.
Rest. In the past, bedrest was advised as part of conservative management. The current recommendation is 1 or 2 days of bedrest, followed by a careful, gradual increase in activity.

Physical Therapy. Physical therapy can be very useful for some patients. A gradually progressive course of exercise strengthens the muscles. This is particularly important in the lumbar area, where the muscles help stabilize the spine. Techniques such as ultrasound, electrical stimulation, heat, ice, and deep massage can decrease pain and muscle spasm and allow for increased ROM. Instructions in proper body mechanics and strategies for avoiding reinjury are important components of physical therapy.

Traction. Cervical traction is a noninvasive technique sometimes used by physical therapists for patients with herniated cervical disks. The patient’s head is placed in a halter-like device. A series of ropes and pulleys connect the halter to a weight. This gently pulls the head away from the shoulders. The rationale is that this traction slightly separates the vertebral bodies and can allow the disk to return to its proper position. If it is effective in relieving the patient’s pain, cervical traction can be done at home on an as-needed basis. Traction is discontinued immediately if it increases the patient’s pain. Lumbar traction is not particularly effective because the lumbar paraspinal muscles are large and strong. The amount of traction needed to overcome the muscular resistance can cause injury.

Medication. Muscle relaxants are often prescribed as a short-term therapy for patients who are experiencing muscle spasms. These medications decrease pain by decreasing the spasm, helping the patient increase range of motion and activity. Muscle spasm is actually a protective mechanism. Muscles tighten and become painful, causing the patient to limit movement. This lessens the chance that the disk will be further injured. However, chronic spasm can cause tearing and scarring of the muscles. Patients should be warned that drowsiness is a common side effect of many muscle relaxants. They should be cautioned against driving or operating machinery until they determine how well they tolerate the medication. Diazepam is an effective muscle relaxant; however, it has a strong potential for addiction, so it is usually used only if muscle spasm cannot be adequately treated with other medications.

Inflammation of the nerve root is caused by compression and irritation from the herniated disk. NSAIDs can be effective in reducing this inflammation, but there is no way to predict response to a given drug. It may be necessary for the patient to try several NSAIDs before an effective one is found. Because several of these drugs are now available without prescription, the patient should be cautioned not to use a nonprescription NSAID at the same time as a prescription NSAID. Patients should be instructed to report any stomach upset to the clinician because NSAIDs can cause gastric bleeding. Occasionally, oral steroids are used on a short-term basis for patients with severe inflammation that does not respond to other treatments. A rapidly tapering dose of steroid over 1 week is often prescribed. Steroids can also cause gastric upset, in addition to elevated serum glucose levels. Insulin must be adjusted to keep glucose levels closely monitored and can be adjusted if the levels are outside their normal parameters.

Epidural injections may be tried for patients who have not responded to more conservative measures. A mixture of medications, typically a steroid, long-acting anesthetic, and long-acting pain reliever, is injected into the epidural space. The anesthetic provides immediate relief, while the steroid reduces swelling for a longer lasting effect. If relief is obtained, the injection can be repeated every 3 to 4 months.

The use of opioid pain medication is a subject of concern in the treatment of patients with herniated disks. Opioids generally are appropriate for short-term treatment of acute pain. However, if treatment is not effective, the pain can become
chronic. In that circumstance, the physician and patient must discuss the potential complications of long-term opioid use, such as constipation, tolerance, and dependence. A referral to a pain clinic for alternative strategies may be appropriate.

Some alternatives to long-term use of opioids include topical lidocaine patches or NSAID patches, or use of agents for neuropathic pain such as pregabalin (Lyrica) or amitriptyline (Elavil).

**Complementary and Alternative Therapy.** A transcervical electrical nerve stimulator (commonly called a TENS unit) is a noninvasive pain-relief technique. Small electrodes are placed on the skin around the area of the pain. The device then transmits a low-voltage electrical current through the skin. The patient feels a tingling or buzzing sensation, which can help block the pain impulses. A physical therapist or pain specialist teaches the patient where to place the electrodes and how to operate the unit. The patient decides when to use it and at what settings. This allows the patient to actively participate in his or her care and have some control over the pain level.

**Surgical Management.** Surgeries are less common today than in the past, because conservative measures have been found to be successful for most patients. If surgery is indicated, several options are available. A laminectomy removes one of the laminae, the flat pieces of bone on each side of a vertebra. This may be done to relieve pressure or to gain access for removal of a herniated disk. A diskectomy removes the entire disk. A spinal fusion uses a bone graft to fuse two vertebrae together if the area is unstable. Surgery can be done through a microscope for less scarring and faster recovery. Most patients are discharged within 24 hours of surgery.

A diskectomy is generally done for a herniated cervical disk. This can be accomplished via an anterior or posterior approach. Most surgeons use the anterior approach for cervical herniations because the muscles in the front of the neck are much smaller and more mobile than those in the back of the neck. Therefore, there is less pain and muscle spasm following surgery. It is also safer than the posterior approach, which involves more maneuvering around the spinal cord.

Most surgeons replace the disk with bone or another material. This prevents collapse of the disk space and creates a spinal fusion. If bone is used, it may be harvested from the patient’s iliac crest or donated from a cadaver. Mobility of the spine is lost in the area of a fusion. Spinal fusions may also be done to correct instability of the spine from other causes, such as scoliosis or degenerative disorders.

A posterior approach is used for a herniated lumbar disk. Typically, the vertical incision is 1 to 2 inches long. It is necessary to pull some of the muscle away from the bone, which accounts for some of the postoperative pain patients experience. A laminectomy is done, and the herniated portion of the disk is resected. The remainder of the disk continues to provide a cushion between the intra vertebral bodies. The surgeon removes any free fragments and any disk material that appears unstable.

Percutaneous diskectomy involves insertion of a large needle into the disk under local anesthesia to aspirate herniated disk material. This technique is not used for severely herniated disks. Laser disk surgery may be used to disintegrate the herniated tissue. Laparoscopic techniques may also be used.

In 2004, the U.S. Food and Drug Administration approved an artificial disk for use with selected patients. It is made of two plastic disks designed to slide so that mobility is not impaired as with spinal fusion. The artificial disk is attached to the vertebra above and below after the damaged disk is removed. This alternative to spinal fusion has been effective for those with single-disk problems.

**Complications After Surgery**

**Hemorrhage.** As with any surgery, intraoperative hemorrhage is possible, although it is not common in disk surgery. If a postoperative hemorrhage occurs in a patient who has had an anterior cervical diskectomy, the airway can become occluded. The patient is monitored for bleeding from the incision and respiratory distress.

**Nerve Root Damage.** If the nerve root is severed during surgery, the patient experiences loss of motor and sensory functions in that nerve’s distribution area. This can result in decreased use of the extremity. If the nerve root is damaged or excessive scarring occurs, the patient can experience pain, weakness, or paresthesias. In some cases, physical therapy and NSAIDs may be effective in improving function and reducing pain.

**Reherniation.** Lumbar disks can reherniate. This can occur anywhere from 1 week to several years after the initial surgery. If the reherniation occurs within a few weeks to months after the first surgery, the patient usually undergoes another microdiskectomy. Reherniation of a cervical disk does not occur because the entire disk is removed.

**Herniation of Adjacent Disk.** Fusion of the cervical spine results in loss of motion at that motion segment. This can place increased stress on the disks above and below the fusion. This can increase the risk of another herniated disk, especially if the patient already has degeneration of other disks. The patient should be instructed to maintain an exercise program and to frequently move the spine through ROM exercises.

**Nursing Process for the Patient Having Spinal Surgery**

**Preoperative Care**

Routine preoperative care is appropriate for the patient undergoing spinal surgery. In addition to routine teaching, instruct the patient in how to logroll following surgery. This procedure involves keeping the body in alignment and rolling as a unit, without twisting the spine, to prevent injury to the operative site.
Postoperative Care

DATA COLLECTION. In addition to routine postoperative data collection, monitor extremities for changes in circulation, movement, and sensation. Monitor color, warmth, and presence of pulses in the extremities. Assess movement by asking the patient to move the extremities. Assess sensation by gently touching the patient’s extremity and asking if feeling is present. Report any changes immediately to the physician because this can indicate nerve or circulatory damage.

Monitor pain frequently. The pain that necessitated surgery should be relieved, but the patient can still have muscular and incisional pain. Reassure the patient that it will gradually subside. Monitor the surgical dressing and drain (if present) for CSF drainage or bleeding. Any sign of CSF drainage or significant bleeding should be reported to the physician immediately. If bone was taken from a separate donor site, this site must also be monitored. Intake and output are measured to ensure that the patient is able to void. Notify the physician if the patient has difficulty voiding.

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.

Goals of nursing are to keep the patient safe and free from injury or complications, and free from pain. Gradual return to normal physical activity is expected. Possible postoperative diagnoses are discussed next.

Acute Pain related to surgical procedure as evidenced by patient’s pain rating

**EXPECTED OUTCOME:** The patient will verbalize an acceptable pain level.

- Monitor pain following surgery using an appropriate pain scale. The patient’s self-report is the most reliable method for assessing pain.
- Administer muscle relaxants, analgesics, and NSAIDs as ordered. If a local anesthetic was injected into the surgical site during surgery, the patient may not have pain immediately postoperatively. Medications to relieve pain help the patient to mobilize following surgery, which helps prevent complications.
- Position the patient in bed in correct body alignment. If ordered, keep the patient flat for 6 to 8 hours. Correct alignment avoids twisting and injury to the operative site.
- Place a pillow between the legs when lying on the side to promote alignment and comfort.

Risk for Impaired Urinary Elimination related to effects of surgery

**EXPECTED OUTCOME:** The patient will be able to empty bladder without assistance.

- Monitor urine output for retention. Patients may have difficulty voiding following lumbar surgery because of anesthesia, immobility, or occasionally because of nerve damage related to surgery.
- If activity orders allow, assist the patient to get up to urinate (or to stand for men). This may help the patient urinate.
- If unable to void, try running warm water over the perineum, or taking a warm bath or shower. This may stimulate voiding.

Spinal Stenosis

Spinal stenosis is a condition in which the spinal canal compresses the spinal cord (Fig. 48.10). Arthritis is a major cause of spinal stenosis. The facet joints of the spine become

- If difficulty urinating occurs, contact the physician for an order for intermittent catheterization until the problem resolves. Urine retention that is not resolved can lead to bladder rupture. Intermittent catheterization is a safe way to empty the bladder.

Risk for Impaired Physical Mobility related to neuromuscular impairment

**EXPECTED OUTCOME:** The patient will be able to ambulate and prevent complications of immobility after surgery.

- Assess mobility of affected extremities following surgery. A reduction in expected mobility following surgery indicates nerve damage in surgery and should be reported immediately.
- Assist the patient to logroll to get out of bed and ambulate on the first postoperative day, as ordered. If spinal fusion has been done, the fused area of the spine will be immobile. Early mobilization after surgery helps prevent complications.
- Apply a soft cervical collar to the patient with a cervical laminectomy as ordered for neck support.

EVALUATION. The patient is expected to be free of complications and pain, be able to urinate, be able to move all extremities, and return gradually to preillness activity level.
inflamed and enlarged, narrowing the diameter of the spinal canal and compressing the spinal cord. Patients may report pain and weakness. Compression of the cervical portion of the spinal cord can result in hyperreflexia and weakness of the legs and arms.

A laminectomy may be done to relieve pressure on the spinal cord. The size of the incision depends on the number of vertebrae involved. These patients are often older and may have concurrent illnesses. They may require inpatient rehabilitation before returning home.

**SPINAL CORD INJURIES**

Injuries to the spinal cord affect people of all ages but take their greatest toll on young people. These injuries are characterized by a decrease or loss of sensory and motor functions below the level of the injury.

**Pathophysiology**

The spinal cord is made up of nerve fibers that allow communication between the brain and the rest of the body. Damage to the spinal cord results in interference with this communication process. Damage may be caused by bruising, tearing, cutting, edema, or bleeding into the cord. The damage can be caused by external forces or by fragments of fractured bone.

**Etiology and Types**

The causes of spinal cord injury are similar to those of traumatic brain injury. It is not uncommon for a patient to have both a spinal cord injury and traumatic brain injury. Motor vehicle accidents are the most common causes of spinal cord injury in the United States. Females are more often injured by falls and males are more often injured during acts of violence or contact sports. Assaults can cause cord injury if a knife or bullet penetrates the spinal cord. Diving into shallow water is a common cause of cervical cord injury.

Spinal cord injuries can be classified by location or by degree of damage to the cord. A complete spinal cord injury means that there is no motor or sensory function below the level of the injury. With an incomplete lesion, some function remains. This does not necessarily mean that the remaining function will be useful to the patient. Some patients find that having areas where sensation is intact may be more painful than useful.

The cervical and lumbar portions of the spine are injured more often than the thoracic or sacral segments. This is because the cervical and lumbar areas are the most mobile portions of the spine.

**Signs and Symptoms**

**Cervical Injuries**

Signs and symptoms depend on the level at which the cord is damaged (Fig. 48.11). Cervical cord injuries can affect all four extremities, causing paralysis and paresthesias, impaired respiration, and loss of bowel and bladder control. Paralysis of all four extremities is called quadriplegia; weakness of all extremities is called quadriparesis. If the injury is at C3 or above, the injury is usually fatal because muscles used for breathing are paralyzed. An injury at the fourth or fifth cervical vertebra affects breathing and may necessitate some type of ventilatory support. Such patients typically need long-term assistance with activities of daily living.

**Thoracic and Lumbar Injuries**

Thoracic and lumbar injuries affect the legs, bowel, and bladder. Paralysis of the legs is called paraplegia; weakness of the legs is called paraparesis. Sacral injuries affect bowel and bladder continence and may affect foot function. Individuals with thoracic, lumbar, and sacral injuries can usually learn to perform activities of daily living independently.

**Spinal Shock**

Spinal cord injury has a profound effect on the autonomic nervous system. Immediately after injury, the cord below the injury stops functioning completely. This causes a disruption of sympathetic nervous system function, resulting in vasodilation, hypotension, and bradycardia—called neurogenic shock or spinal shock. Dilution of the blood vessels allows more blood flow just beneath the skin. This blood cools and is circulated throughout the body, causing hypothermia. The patient is unable to maintain control of body temperature. In addition, all reflexes below the level of the injury are lost, and retention of urine and feces occurs. Spinal shock can last from a week to many weeks in some patients.

**Complications**

**Infection**

Impaired respiratory effort, decreased cough, mechanical ventilation, and immobility all predispose a patient with a spinal cord injury to pneumonia. Urinary catheterization, whether indwelling or intermittent, places patients at risk for urinary tract infection.

**Deep Venous Thrombosis**

Lack of movement in the legs inhibits normal blood circulation. Compression stockings, sequential compression devices, and subcutaneous heparin or enoxaparin may be used to reduce the risk of deep venous thrombosis.

**Orthostatic Hypotension**

Most patients with spinal cord injuries no longer have muscular function in their legs to promote venous return to the heart. They also have impaired vasoconstriction. This leads to pooling of the blood in the legs when the patient moves from a supine to a sitting position. If the movement is sudden, the patient can become dizzy or light-headed. Gradual elevation of the legs may help to reduce symptoms.

**Word Building**

quad—four + plegia—paralysis
quadriparesis: quad—four + paresis—partial paralysis
paraplegia: para—beside + plegia—paralysis
paraparesis: para—beside + paresis—partial paralysis
of the head, use of elastic stockings, and a reclining wheel-
chair help lessen this response.

Skin Breakdown

Patients or their caregivers must be diligent about relieving
pressure on the skin by position changes and cushioning of
bony prominences. It is important to realize that the patient
may not be able to feel pain and therefore may not ask for
position changes. Development of pressure ulcers can lead
to infection and loss of skin, muscle, or bone. Treatment
of pressure ulcers is time-consuming and expensive and can
interfere with work or school.

Renal Complications

Urinary tract infections are an ongoing concern for patients
with spinal cord injuries. Caregivers as well as the patient
need to be taught to observe the color, clarity, and odor of
urine and to report changes promptly. Both urinary reflux and
untreated urinary tract infections can cause permanent damage to the kidneys.

**Depression and Substance Abuse**

Patients with spinal cord injury have a higher than a verage incidence of depression and substance abuse. Both of these factors can interfere with the patient’s ability to care for himself or herself. Individual or family counseling may be helpful. Some rehabilitation centers have support groups for patients with spinal cord injuries.

**Autonomic Dysreflexia**

This life-threatening complication occurs in patients with injuries above the T6 level. The spinal cord injury impairs the normal equilibrium between the sympathetic and parasympathetic divisions of the autonomic nervous system. If a noxious stimulus below the spinal cord injury causes activation of the sympathetic system, it will continue unchecked because the parasympathetic responses cannot descend past the spinal cord injury.

The most common cause of autonomic dysreflexia is bladder distention. Other causes include bowel impaction, urinary tract infection, ingrown toenails, pressure ulcers, pain, and labor in a pregnant woman. Stimulation of the sympathetic nervous system results in cool, pale skin, gooseflesh, and vasoconstriction below the level of the injury. Blood pressure can rise as high as 300 mm Hg systolic. The parasympathetic response results in vasodilation, causing flushing and diaphoresis above the lesion, and bradycardia as low as 30 beats per minute. The patient reports a pounding headache and nasal congestion secondary to the dilated blood vessels.

Care of the patient with autonomic dysreflexia is discussed in the care plan later in this section.

**Diagnostic Tests**

Plain radiographs are done to identify fractures or displacement of vertebrae. A CT scan is also useful for identifying fractures. An MRI can demonstrate lesions within the cord.

**Therapeutic Measures**

Patients with spinal cord injuries typically are brought to the emergency department. They should be kept immobilized until they are assessed by a physician. If injury to the spinal cord is detected, the patient needs to remain immobilized.

**Emergency Management**

Emergency management involves careful monitoring of vital signs and airway and keeping the patient immobilized. Intubation and mechanical ventilation may be necessary, especially with cervical spine injuries. IV normal saline may be used for fluid replacement and provision of an access site for medication administration. The physician does not rely on fluid administration alone to correct hypotension. It is possible to administer enough fluid to cause pulmonary edema and not correct the hypotension. Vasoactive drugs may be required. The use of various medications to reduce the extent of injury, including IV methylprednisolone (a steroid), is routine. Often treatment is started by emergency medical services (EMS) personnel before arrival at the emergency department.

**Respiratory Management**

Patients with injuries above C4–C5 have some degree of respiratory impairment. The patient may require a tracheostomy and continuous mechanical ventilation or require a ventilator only at night or when fatigued. Some patients are able to breathe by using a phrenic nerve stimulator. This device, similar to a pacemaker, artificially stimulates the phrenic nerve, causing the diaphragm to contract. These patients use a mechanical ventilator at night to lessen the stress on the phrenic nerve and remove the risk of the system failing while the patient is asleep.

Patients can be breathing independently when they first arrive in the emergency department and then experience respiratory compromise as the spinal cord becomes edematous. Edema can compress the spinal cord above the lesion, leading to symptoms at a higher level. This deterioration is usually temporary. Fatigue of the accessory muscles can also cause respiratory compromise. The intercostal muscles are not normally of major importance in respiration. However, if the diaphragm is paralyzed, the intercostal muscles become very important. As these muscles fatigue, the patient’s breathing becomes shallow and rapid. Elective intubation and mechanical ventilation protect the patient from expending huge amounts of energy trying to breathe. Feeling their breathing becoming more labored is terrifying to these patients, and they need to be reassured that it is probably a temporary setback. As the edema recedes and the accessory muscles become stronger, the patient may be weaned from the ventilator.

**Gastrointestinal Management**

Absence of bowel sounds is a common finding on examination. Oral or enteral feedings are not started until bowel function resumes. The metabolic needs of the patients are influenced by the work of breathing and the extent of other injuries. If positioning or paralytic ileus precludes oral or enteral feedings, IV hyperalimentation is begun.

**Genitourinary Management**

An indwelling urinary catheter is placed to prevent bladder distention and protect skin integrity until spinal shock resolves. Once it is determined what degree of hand function the patient will have, a bladder management program is devised.

**Immobilization**

The cervical spine can be immobilized with skeletal traction such as Crutchfield or Gardner-Wells tongs (Fig. 48.12). Some patients have a halo brace, a device that attaches to the skull with four small pins. The skull ring attaches to a rigid plastic vest by four poles (Fig. 48.13). This device keeps the head and neck immobile while fusion and healing take place. The advantage over traction is that the patient is not confined to bed.

**Surgical Management**

The goal of surgery following spinal cord injury is to stabilize the bony elements of the spine and relieve pressure on the
spinal cord. Surgery may or may not improve functional outcome. Stabilization of the spine allows for earlier mobilization of the patient. This decreases the risk of complications from immobility and speeds the transition to a rehabilitation setting. Patients who have been in cervical traction before surgery may be placed in a halo brace postoperatively.

Unstable thoracic and lumbar fractures may also be treated with surgical implantation of rods to stabilize the spine. It is more difficult to stabilize these areas in the postoperative recovery period. Patients may wear a supportive corset, a rigid brace, or occasionally a body cast to supplement the support provided by the internal fixation devices. For more information, visit the Spinal Cord Injury Information Network at www.spinalcord.uab.edu.

Research is being conducted now with stem cells to help with nerve regeneration. Stem cells can be harvested and then processed in a laboratory before reinjection into the body. The goal is improvement in mobility and/or sensation.

**Nursing Process for the Patient With a Spinal Cord Injury**

Patients with spinal cord injury need ongoing evaluation of all body systems. Frequent neurologic and respiratory assessments are essential. Early assessment of the patient’s support systems can help with discharge and rehabilitation planning. Initial goals for the patient include maintenance of safety and prevention of complications. Long-term goals include rehabilitation and maximizing remaining function.

See the “Nursing Care Plan for the Patient With a Spinal Cord Injury,” “Gerontological Issues,” and Table 48.8.

**Gerontological Issues**

**Aging With Spinal Cord Injury**

Individuals aging with a spinal cord injury have an increased risk for developing complications in the following areas:

- Blood pressure control
- Abnormalities in carbohydrate and lipid metabolism related to immobilization
- Cardiovascular disease
- Respiratory complications
- Osteoporosis
- Bladder infections
- Skin ulcers
- Chronic pain
# NURSING CARE PLAN for the Patient With a Spinal Cord Injury

**Nursing Diagnosis:** *Impaired Gas Exchange* related to respiratory muscle weakness as evidenced by Spo₂ less than 90%, abnormal ABGs

**Expected Outcome:** The patient will maintain oxygenation as evidenced by Spo₂ of 90% or greater, PaO₂ of 75 mm Hg or greater, PaCO₂ of 45 mm Hg or less.

**Evaluation of Outcome:** Are ABGs and Spo₂ within normal limits?

**Intervention** Monitor respiratory rate, effort, ABGs, and Spo₂. **Rationale** These are indicators of respiratory function. The patient may have difficulty maintaining normal respiration if diaphragm or accessory muscles are weak related to injury.  
**Evaluation** Are ABGs and SaO₂ within normal limits? Does patient appear distressed?

**Intervention** Notify physician immediately if Spo₂ or PaO₂ drops, or if PaCO₂ rises. **Rationale** If patient is unable to maintain blood gases, mechanical ventilation may be needed.  
**Evaluation** Are changes recognized and reported promptly?

**Nursing Diagnosis:** *Ineffective Airway Clearance* related to ineffective cough and decreased muscle control as evidenced by adventitious breath sounds, Spo₂ less than 90%

**Expected Outcome:** The patient will maintain a clear airway as evidenced by clear breath sounds and Spo₂ of 90% or greater.

**Evaluation of Outcome:** Are breath sounds clear? Is Spo₂ 90% or greater?

**Intervention** Monitor cough and lung sounds. **Rationale** Patient may not have adequate muscle strength to cough effectively.  
**Evaluation** Is patient able to cough up secretions? Is there evidence that secretions are retained?

**Intervention** Suction patient prn if unable to cough effectively. **Rationale** To keep the airway clear.  
**Evaluation** Is suctioning effective in clearing airway?

**Intervention** Once the patient is stable, try assisting him or her to cough to clear secretions. Gently push upward and inward on the patient’s chest while he or she coughs as strongly as possible. **Rationale** This can help the patient clear secretions without invasive suctioning. This is similar to the Heimlich maneuver but not as forceful.  
**Evaluation** Does the assisted cough technique help the patient to clear the airway?

**Intervention** Provide humidified air and oral or enteral fluids. **Rationale** Humidification helps keep secretions thin and mobile.  
**Evaluation** Are secretions thin and easily expectorated?

**Nursing Diagnosis:** *Risk for Autonomic Dysreflexia* related to stimuli below the level of injury

**Expected Outcomes:** The patient will not demonstrate signs of autonomic dysreflexia as evidenced by stable vital signs. If dysreflexia occurs, it is recognized and corrected promptly.

**Evaluation of Outcomes:** Is patient free of signs or are signs recognized and promptly treated?

**Intervention** Monitor for signs of autonomic dysreflexia: sudden high blood pressure, bradycardia, headache, pale skin below the injury, gooseflesh. Remember that patients with spinal cord injury are typically hypotensive, so a finding of even mild hypertension can represent a dramatic increase from their baseline blood pressure. **Rationale** Autonomic dysreflexia must be recognized quickly to remove cause and prevent complications such as seizures, intracerebral hemorrhage, or death.  
**Evaluation** Are signs of dysreflexia present?
NURSING CARE PLAN for the Patient With a Spinal Cord Injury—cont’d

**Intervention** If you suspect autonomic dysreflexia, immediately take the patient’s blood pressure and continue to monitor it every 5 minutes. **Rationale** Blood pressure must be continually monitored until it is under control, to prevent complications. **Evaluation** Is blood pressure higher than normal for patient? Are emergency interventions warranted?

**Intervention** Place the patient in high-Fowler’s position. Remove elastic stockings or any other garment that could prevent blood from pooling in the periphery. **Rationale** High-Fowler’s position uses the effect of orthostasis to control blood pressure. Allowing blood to pool in periphery can help reduce blood pressure. **Evaluation** Does position change reduce blood pressure?

**Intervention** Evaluate the indwelling catheter for patency. If it is not patent or a catheter is not in place and the bladder is full, obtain an order to insert a catheter immediately. Monitor blood pressure during catheterization. **Rationale** A full bladder can be the cause of the stimuli causing the dysreflexia. **Evaluation** Is catheter patent? Is bladder full? Does emptying bladder resolve dysreflexia?

**Intervention** Perform a rectal examination to determine if an impaction is present. Apply anesthetic ointment to the rectum before disimpaction. Simultaneously monitor blood pressure and stop disimpaction if the blood pressure increases. **Rationale** Fecal impaction can be the stimulus causing the dysreflexia. Anesthetic is used because further rectal stimulation can exacerbate symptoms. **Evaluation** Is impaction present? Does removal resolve dysreflexia?

**Intervention** If bowel or bladder distention is not present, examine the patient for other causative mechanisms. If a cause cannot be identified, or removal of the cause does not relieve hypertension, notify the physician immediately. **Rationale** If the cause cannot be found and removed, an antihypertensive agent may be ordered. **Evaluation** Are other causes identifiable? Is an antihypertensive agent ordered?

**Intervention** If hypertension is treated with medication, continue to carefully monitor blood pressure. **Rationale** Blood pressure can decrease rapidly once the cause of the autonomic dysreflexia is corrected. **Evaluation** Is blood pressure stabilized?

**Intervention** Once the acute episode is past, work with patient and significant others to devise a plan to prevent reoccurrence. Teach the patient how to direct caregivers in treating autonomic dysreflexia. **Rationale** Episodes of dysreflexia can recur, and most can be prevented. **Evaluation** Do patient and caregivers verbalize understanding of how to prevent and treat future episodes of dysreflexia?

**Nursing Diagnosis:** Reflex Urinary Incontinence related to spinal cord damage and no sensation to void as evidenced by inability to control flow of urine

**Expected Outcomes:** The patient’s skin will be dry and free of urine; urine elimination will be controlled.

**Evaluation of Outcomes:** Is patient clean and dry at all times?

**Intervention** Assess patient’s ability to control urination. **Rationale** If patient has some control, a bladder training program may be effective. **Evaluation** Is patient able to sense need to urinate? Is any degree of control present?

**Intervention** Implement a bladder training program, using set times for voiding. **Rationale** Following a voiding schedule can help reduce incontinence. **Evaluation** Is patient able to avoid incontinence with regular voiding?

**Intervention** Use bladder ultrasound to scan bladder for residual urine. **Rationale** Incomplete voiding can increase risk for urinary tract infection. **Evaluation** Is patient effectively emptying bladder?

**Intervention** Teach the patient or caregiver self-catheterization as ordered, if bladder training is not effective. **Rationale** Intermittent self-catheterization is associated with fewer complications than an indwelling catheter. **Evaluation** Is patient able to perform self-catheterization correctly?
NURSING CARE PLAN for the Patient With a Spinal Cord Injury—cont’d

**Intervention** Monitor appearance of urine, temperature, and white cell count. **Rationale** Cloudy urine, and an increase in temperature and white cell count indicate urinary tract infection. **Evaluation** Is urine clear, and temperature and white blood cell count within normal limits?

**Intervention** Consult with physician regarding indwelling Foley catheter if patient is not a candidate for intermittent self-catheterization. **Rationale** An indwelling catheter can increase risk for infection, but may be necessary as a last resort for some patients. **Evaluation** Is Foley catheter necessary? Are signs of infection avoided?

**Nursing Diagnosis:** Constipation related to immobility and nerve damage as evidenced by passage of hard, dry, or infrequent stools

**Expected Outcome:** The patient will return to preinjury bowel pattern.

**Evaluation of Outcome:** Does patient pass soft stool at regular intervals?

**Intervention** Assess previous and current bowel pattern and continence. **Rationale** Decreased or absent sphincter tone, inability to detect the need to defecate, and immobility put the patient at risk for incontinence and constipation. **Evaluation** What was previous pattern? How can it be maintained for the patient?

**Intervention** Monitor bowel sounds and abdominal distention. **Rationale** These are indicators of bowel function. **Evaluation** Are bowel sounds present? Is abdomen soft?

**Intervention** Institute a bowel management program as soon as oral feedings are resumed. Include a suppository on a scheduled daily or every-other-day basis as ordered. **Rationale** A management program including stool softeners and routine suppository use can help to restore regular defecation. **Evaluation** Does management program keep bowel movements soft and regular and maintain continence?

**Intervention** If possible, have patient sit on a toilet or bedside commode to move bowels. **Rationale** Sitting allows gravity to help evacuate the bowel. **Evaluation** Does sitting help patient move bowels?

**Intervention** Provide a high-fiber diet with adequate fluid intake. **Rationale** Fiber and fluids help keep stool soft. **Evaluation** Is patient receiving adequate fiber and fluids?

**Nursing Diagnosis:** Impaired Physical Mobility related to hemorrhage, ischemia, and edema of cord as evidenced by paresis or paralysis

**Expected Outcomes:** The patient will maintain maximum mobility and be free from complications of immobility.

**Evaluation of Outcomes:** Is patient kept mobile without contractures? Is skin intact? Can patient complete ADLs with assistance?

**Intervention** Determine patient’s ability to move independently. **Rationale** Assessment should guide interventions. **Evaluation** What can patient do independently?

**Intervention** Assess patient’s ability to feel pressure and pain. **Rationale** If the patient is unable to feel pain or pressure, it will be even more important to monitor skin and prevent prolonged pressure. **Evaluation** Can patient feel pressure and pain?

**Intervention** Reposition every 2 hours, using supportive devices. **Rationale** Unrelieved pressure on the skin, especially bony prominences, will result in ischemia and necrosis. **Evaluation** Is skin intact without redness?

**Intervention** Change positions slowly; have patient sit at side of bed before standing (if able) or getting up to a chair. **Rationale** Patients with cervical spine injuries or patients remaining immobile for long periods are prone to orthostatic hypotension. **Evaluation** Does patient become dizzy when getting up?
**NURSING CARE PLAN for the Patient With a Spinal Cord Injury—cont’d**

**Intervention** Perform active or passive ROM exercises at least once every 8 hours. If patient has arm mobility, teach patient to participate in doing as much ROM as possible. **Rationale** ROM exercises maintain mobility and prevent contractures. **Evaluation** Is patient able to perform ROM exercises with minimal difficulty?

**Intervention** Teach patient importance of repositioning self at least every 2 hours. **Rationale** Patients with some mobility can learn to reposition themselves; this helps prevent total dependence on caregivers. **Evaluation** Does patient demonstrate correct repositioning every 2 hours?

**Intervention** Teach patient to direct own care, if unable to reposition independently. **Rationale** This allows the patient some control over his or her situation. **Evaluation** Does patient direct own care and prevent complications of immobility?

**Nursing Diagnosis:** *Self-Care Deficit* related to paralysis

**Expected Outcome:** The patient’s self-care needs will be met by self or caregivers.

**Evaluation of Outcome:** Are patient’s needs met? Does patient verbalize satisfaction with care?

**Intervention** Determine patient’s level of function and ability to perform ADLs. **Rationale** The patient should be encouraged to be as independent as possible. **Evaluation** What is patient able to do? Is it incorporated into plan of care?

**Intervention** Explain the rationale for nursing activities, and encourage the patient and significant others to participate in hands-on care as much as possible. **Rationale** This will help prepare the patient and significant others to assume responsibility for care at home. **Evaluation** Do patient and significant others verbalize understanding of care? Are they able to demonstrate procedures correctly?

**Intervention** If the patient will not be able to perform self-care, assist him or her to learn to direct care. **Rationale** This allows the patient some control over his or her care. **Evaluation** Does patient participate by directing care?

**Intervention** Consult with physical and occupational therapists. **Rationale** Physical and occupational therapists can help the patient learn to adapt to physical limitations; they can provide a wheelchair or other mobility aids. **Evaluation** Is patient adapting to limitations with help?

**Intervention** Discuss discharge to a rehabilitation facility with patient, physician, and discharge planner. **Rationale** A rehabilitation facility can teach the patient to function independently. Some patients may require long-term care. **Evaluation** Is the patient a candidate for rehabilitation?

**Intervention** Assist patients and caregivers to determine contingency plans. These include what to do in the event of a power failure, fire, or illness of the caregiver. **Rationale** Planning ahead what to do in an emergency can mean the difference between life and death for an immobile patient. **Evaluation** Do patient and caregivers have a plan to keep the patient safe?

**Intervention** Encourage the patient to establish a relationship with a primary practitioner who is familiar with spinal cord injury. **Rationale** Patients with spinal cord injuries experience the same basic health care needs as individuals without injuries. **Evaluation** Does patient have a primary care practitioner who understands his or her unique needs?

**Nursing Diagnosis:** *Risk for Impaired Skin Integrity* related to immobility and possible paresthesias

**Expected Outcome:** The patient’s skin will remain intact without redness or breakdown.

**Evaluation of Outcome:** Is patient’s skin intact?
**NURSING CARE PLAN for the Patient With a Spinal Cord Injury—cont’d**

**Intervention** Monitor skin frequently. When permitted by the physician, turn the patient frequently and assess bony prominences for redness. **Rationale** The patient who does not have sensation is at increased risk of developing pressure ulcers. **Evaluation** Is the patient turned and repositioned at least every 2 hours? Is skin intact?

**Intervention** Start preventive measures in the emergency department by being sure to remove anything between the patient and the backboard. **Rationale** Patients have developed pressure ulcers from lying on keys or other objects in their pockets. **Evaluation** Are skin surfaces protected from pressure?

**Intervention** Use a pressure-reducing mattress. **Rationale** Specialty mattresses or beds can reduce pressure, but do not reduce the need to turn the patient. **Evaluation** Is the patient on an appropriate mattress?

**Intervention** If on a self-turning bed, make sure the patient is not sliding as the bed turns. Avoid pulling and friction on skin when repositioning patient in bed. **Rationale** Sliding can cause friction and shearing damage to the skin. **Evaluation** Is friction damage to skin avoided?

**Intervention** Ensure that the patient’s extremities do not get caught in side rails or wheelchair spokes. **Rationale** The patient may not be aware this is happening, and a pressure ulcer can result. **Evaluation** Are all patient’s body parts accounted for and safe?

**Intervention** If a patient is in traction or a halo brace, assess pin sites frequently. Keep the sites clean and dry, and report any sign of infection. **Rationale** Skin sites are at risk for infection and breakdown. **Evaluation** Are pin sites clean and dry?

**Intervention** Monitor temperature of bath water (no more than 102 degrees F). **Rationale** Patient may not be able to feel burning if water is too hot. **Evaluation** Are burns prevented?

**Nursing Diagnosis:** *Risk for Ineffective Role Performance* related to effects of injury

**Expected Outcome:** The patient will identify new ways to carry out essential roles.

**Evaluation of Outcome:** Is patient able to identify ways to carry out roles?

**Intervention** Allow the patient to verbalize concerns about his or her roles if desired. **Rationale** This can help to clarify potential role problems for the patient, and begin the process of developing a plan. **Evaluation** Is patient able to identify roles he or she has filled in the past that will be difficult to carry out due to injury?

**Intervention** Help patient and family to identify resources. **Rationale** Interpersonal relationships can be significantly stressed by spinal cord injury. Friends, family, and members of the patient’s religious affiliation can provide emotional and physical help. **Evaluation** Does patient have adequate support systems in place to provide help?

**Intervention** Consult a social worker to help the patient gain access to appropriate physical and financial assistance. **Rationale** Loss of income can be temporary or permanent and can add to the burden of spinal cord injury. Not all insurance policies cover the extensive inpatient rehabilitation needed by patients with spinal cord injuries. Adaptive equipment is expensive and may not be covered by insurance. **Evaluation** Is patient able to access appropriate financial assistance if needed?

**Intervention** Provide information about area support groups. **Rationale** Individuals who have been through similar experiences can provide support and information for the patient and family. **Evaluation** Is patient willing to contact support groups?

**Nursing Diagnosis:** *Risk for Sexual Dysfunction* related to autonomic nervous system dysfunction

**Expected Outcome:** The patient will state he or she has an acceptable means for sexual expression.

**Evaluation of Outcome:** Does patient state satisfaction with sexual function?
Intervention: If a male patient has an erection during a bath or catheterization, discontinue the procedure and continue at a later time if possible. Maintain a matter-of-fact attitude. Rationale: Male patients with quadriplegia may develop an erection during any penile stimulation. Evaluation: Is patient’s dignity maintained during personal care?

Intervention: Allow patient to voice concerns about sexual function if desired. Rationale: Male patients with paraplegia can have difficulty achieving and maintaining an erection. Evaluation: Is patient able to voice concerns? Is a consult with a urologist or other specialist needed?

Intervention: Encourage the patient and partner to explore alternative methods of sexual expression. Rationale: Closeness and touching may be a satisfying alternative. Evaluation: Is patient able to discuss alternative methods with partner?

Intervention: If a male patient wishes to have children, encourage a consult with a fertility specialist or urologist. Rationale: Men with spinal cord injuries may not ejaculate in the normal manner. A specialist can provide some help for conception if desired. Evaluation: Is patient given information about conception if desired?

Intervention: Advise women who wish to become pregnant to seek an obstetrician familiar with spinal cord injuries. Rationale: A specialist may be needed to meet the unique needs of these patients. Evaluation: Is the patient interested in pregnancy? Does she have the information needed related to pregnancy with spinal cord injury?

Intervention: If the patient does not wish to become pregnant, provide information about contraception. See Table 48.9 for contraception for women with spinal cord injuries. Rationale: Spinal cord injury does not impair female fertility. Evaluation: Does the patient have information and resources to prevent pregnancy if desired?

Intervention: Encourage partners to verbalize feelings about caregiving activities such as catheterizations and make alternative arrangements for care if possible. Some patients with the financial resources to do so may choose to hire an attendant rather than rely on significant others for personal care. Rationale: Performing tasks such as catheterization or bowel care may interfere with feelings of intimacy between partners. Evaluation: Are patient and partner able to discuss feelings about caregiving activities and find alternate arrangements if desired?

Nursing Diagnosis: Anxiety related to change in health status as evidenced by behavioral changes such as insomnia, poor eye contact, and irritability

Expected Outcomes: The patient will participate in rehabilitation activities. The patient will be able to verbalize fears, concerns, and expectations.

Evaluation of Outcomes: Is the patient able to participate in rehabilitation? Does patient verbalize that anxiety is controlled?

Intervention: Allow patient to voice feelings of fear and anxiety. Rationale: Communication is vital to assess the patient’s coping abilities. Evaluation: Is the patient able to verbalize anxiety?

Intervention: Provide information about what is happening to the patient physiologically and about procedures. Rationale: Understanding of what is happening can help the patient cope with changes. Evaluation: Does patient verbalize understanding of what is happening? Does information help keep patient less fearful?

Intervention: Consult a social worker, pastoral care, and/or support groups. Rationale: A social worker or pastor can help provide emotional and spiritual support. Discussing rehabilitation with patients and their families who have had similar experiences can provide insight and encouragement. Evaluation: Does patient state talking with support persons helps reduce anxiety?

Intervention: Encourage the patient to participate in physical and occupational therapy. Rationale: Seeing progress toward becoming independent can help reduce anxiety and fear about the future. Evaluation: Does patient participate in therapies? Is anxiety lessening?
### TABLE 48.8 SPINAL CORD INJURY SUMMARY

| Signs and Symptoms | Flaccid paralysis and paresthesias (depending on level of the lesion)  
| Loss of reflex activity below the level of the lesion  
| Spinal shock initially  
| Risk for autonomic dysreflexia (injuries above sixth thoracic vertebra) |
| Diagnostic Tests | Radiograph  
| CT scan  
| MRI |
| Therapeutic Measures | Immobilization  
| Maintenance of airway and respiratory status  
| Bowel and bladder training  
| Nutrition/diet  
| Activity/rehabilitation  
| Prevention of dysreflexia  
| Prevention of skin breakdown  
| Sexual counseling  
| Education |
| Complications | Infection  
| Deep venous thrombosis  
| Paralysis  
| Orthostatic hypotension  
| Pressure ulcers  
| Depression |
| Priority Nursing Diagnoses | Impaired Gas Exchange  
| Ineffective Airway Clearance  
| Risk for Autonomic Dysreflexia  
| Reflex Urinary Incontinence  
| Constipation  
| Impaired Physical Mobility |

### TABLE 48.9 BIRTH CONTROL ISSUES FOR PATIENTS WITH SPINAL CORD INJURY

| Method | Oral contraceptives |
| Comments | Contraindicated because of the risk of deep venous thrombosis |
| Diaphragm | May be difficult to insert for a patient with poor hand function |
| Intrauterine device | Patient may not feel device move out of position  
| Patient may not feel perforation of uterus |
| Implantable device | No contraindications |
| Condom | No contraindications |

Neurodegenerative is a term that can apply to any nervous system disorder that causes degeneration, or wasting, of the neurons in the nervous system. The disorders discussed in this section are some of the most common neurodegenerative disorders. Neurocognitive is the term used to describe acquired neurological disorders that cause cognitive decline. By 2030, it is estimated that 150 million Americans will have one or more chronic conditions. Management of chronic conditions does not focus on the short-term stay in the hospital due to an exacerbation of the disease process but rather on the long-term goal of facilitating the patient and family to cope with the disease process and maintain the patient’s independence for as long as possible. Nursing care involves providing information on management of the illness, education related to prevention and treatment of complications, and referrals to support groups or case managers. As patients decline, many families will come to a time when they can no longer care for their loved one in their homes and must consider care in a long-term facility.

**Dementia**

Dementia is not a disease but rather a symptom of a number of neurocognitive disorders. According to the National Institute of Neurological Disorders and Stroke (2013), “People with dementia have significantly impaired intellectual functioning that interferes with normal activities and relationships. They also lose their ability to solve problems and maintain emotional control, and they may experience personality changes and behavioral problems, such as agitation, delusions, and hallucinations. While memory loss is a common symptom of dementia, memory loss by itself does not mean that a person has dementia.” Some patients can have mild mental status changes that do not interfere significantly with day-to-day functioning. This is sometimes referred to as mild cognitive impairment, or MCI. However, patients with MCI are more likely to go on to develop Alzheimer’s disease than those without MCI.

**Etiology and Pathophysiology**

There are many causes of dementia, including Huntington’s, Parkinson’s, and Alzheimer’s diseases, which are discussed later in this chapter. Multiple “mini-strokes” (multi-infarct dementia or vascular dementia) are another common cause. Chronic alcoholism, neurologic infections, head injuries, and many medications (Box 48-2) also can cause changes.
in mental status leading to dementia. Although aging is associated with more frequent dementia diagnoses, dementia is not a normal part of aging. Pathophysiologies vary depending on the cause. In general, thinking is affected by changes in the brain that result from reduced blood flow or from structural changes related to disease states.

Much research has been done to determine factors related to dementia; such knowledge helps in its prevention. Some studies indicate that patients who have more education, have higher socioeconomic status, and engage in stimulating intellectual and leisure activities are less likely to develop dementia. Some experts believe these individuals develop a sort of cognitive reserve that keeps them functioning at a high level, even when changes in their brains on autopsy indicate dementia. People with less education, fewer leisure activities, and less intellectual stimulation are more likely to develop symptoms of Alzheimer’s disease.

Signs and Symptoms

Have you ever forgotten something important? Most people have occasional memory lapses. Students may have memory lapses during examinations, but they do not generally have dementia. In patients with dementia, recent memories are usually affected first. Patients may have difficulty recalling whether they ate breakfast or may accuse a family member of not calling when in reality they called just a few hours earlier. This same patient, however, may easily recall an event or even a phone number from childhood.

As patients become more forgetful, they may ask the same questions repeatedly. They can get lost driving or walking in a familiar neighborhood. They can become disoriented to time, and not be a ware of the year. Patients might say that Eisenhower is president, for example, because they remember that as true when they were younger. Later, they may not recognize where they are, and last, they can lose recognition of even their own family members.

Later in the course of the dementia, remote memory can be lost. Patients can forget how to perform simple tasks, such as doing the dishes or making a phone call. They may wander and become lost. Safety is a significant issue with a wandering patient—patients have been found wandering in their nightclothes in the middle of a road, unaware of what they are doing. Patients can develop aphasia and become unable to communicate their needs or follow simple instructions. This can become frustrating to both the family and nursing caregivers. Behavioral problems may necessitate admission to a long-term care facility. In very late stages, the patient becomes totally dependent on caregivers.

Diagnostic Tests

Diagnosis of dementia is twofold: First, dementia must be identified, and then the focus moves to finding the cause of the mental status change. Early diagnosis is essential, because some causes of MCI may be reversible, and early treatment may delay progression. Neuropsychological testing can determine the degree of memory, personality, and behavior changes. The Mini-Mental State Examination is commonly used. The patient should also be tested for depression, which can cause mental status changes but is often easily treated. A review of medications by a knowledgeable nurse, physician, or pharmacist may reveal a medication that is contributing to the mental changes. MRI, CT scan, positron emission tomographic (PET) scan, and blood tests help diagnose underlying causes.

Therapeutic Measures

Medical interventions depend on the cause of the dementia. See Table 48.10 for medications that can be used to delay progression of Alzheimer’s dementia. If medical treatment cannot alter the course of the disease, the focus will shift to delaying progression of symptoms and maintaining patient safety. Excellent nursing care becomes essential for both the patient and family at this point. An important aspect of care in early dementia is determination of the patient’s wishes while the patient is still able to make decisions. Some difficult decisions relate to the patient’s continued ability to drive and live alone. Other decisions related to resuscitation, guardianship, and powers of attorney for health care and finances are essential to discuss.

Nursing Process for the Patient With Dementia

See the “Nursing Care Plan for the Patient With Dementia.”

Delirium

Whereas dementia is chronic and progressive, delirium is a mental disturbance that is temporary and can have either a rapid or gradual onset. Delirium is considered to be a medical emergency and should be diagnosed and treated promptly. Delirium is characterized by disorganized thinking and difficulty staying focused and is seen most commonly in older adults when experiencing an illness. Patients who are severely ill or who have a history of hypertension, alcoholism, or preexisting dementia are most at risk. Many times response to medications is the cause (see Box 48-2). The disturbance can also be the result of anything that is a stressor to the person’s body, such as pain, oxygen deficiency, urinary catheters, fluid and electrolyte imbalances, a change in environment, or nutritional deficiency. Often the most effective nursing intervention is
to have a family member present to assist with orientation and reassurance. Additionally, it is beneficial to have continuity in nursing personnel when possible.

### NURSING CARE TIP

Patients with delirium or dementia must be kept safe, and interventions are similar for both. One important difference, however, is in how you respond to confusion. If a patient is experiencing delirium, reorient him or her to the present time and situation. If a patient with dementia is chronically confused, however, reorientation may not be effective. In this case, validate their feelings. An example would be comforting a patient who is calling for a long-lost parent, rather than reminding the patient the mother has been gone for 30 years.

It is essential that delirium not be mistaken for dementia. If an older adult is hospitalized and exhibits new-onset confusion, consider that it might be delirium. Correcting electrolyte levels, controlling pain, changing medications, or administering oxygen can be helpful in reversing delirium. See the “Nursing Care Plan for the Patient With Dementia” for nursing interventions.

### PARKINSON’S DISEASE

Parkinson’s disease (PD) is a chronic degenerative movement disorder that arises in the basal ganglia in the cerebrum. PD has typically been considered a disease of older adults; however, there are many people with young-onset Parkinson’s. An example is Michael J. Fox (actor and founder of the Michael J. Fox Foundation for Parkinson’s Research), who was diagnosed at age 30. The disease is...
NURSING CARE PLAN  for the Patient With Dementia

Nursing Diagnosis: Risk for Injury related to impaired memory, thought processes, and judgment

Expected Outcome: The patient will remain free from injury.

Evaluation of Outcome: Is patient safe and free from injury? Is environment safe?

Intervention  Monitor patient’s ability to maintain safety. Rationale  As dementia worsens, the patient’s needs change. Evaluation Is patient able to make decisions and negotiate the environment safely?

Intervention  Keep environment simple and familiar; label doors and objects. Keep patient in familiar environment as long as possible. Rationale  Change can result in confusion; even a minor change in furniture arrangement can result in falls. Evaluation Is patient able to make decisions and negotiate the environment safely?

Intervention  Remove harmful objects (scissors, matches); store medicines in locked cabinet; remove knobs from stoves. Rationale  Impaired judgment can make safety a major concern for patients who live at home. Evaluation Is the environment safe for the patient?

Intervention  Make sure patient has eyeglasses and hearing aids if necessary. Rationale  Impaired sensory perception can increase confusion and risk for falls. Evaluation Is patient able to see and hear effectively?

Intervention  Use nightlights; remove throw rugs; use safety gates on stairs. Rationale  These can reduce the risk for falls. Evaluation Is environment set up to reduce risk for falling?

Intervention  Have identification bracelet on patient and ID tags sewn into clothes, and locks on doors to prevent leaving. Rationale  Patients can wander, making them prone to injury. Evaluation Is wandering confined to a monitored area? Is environment set up to allow movement within a safe area?

Intervention  Provide daily walks or exercise. Rationale  Exercise can decrease wandering. Evaluation Does exercise reduce wandering?

Nursing Diagnosis: Imbalanced Nutrition: Less Than Body Requirements related to impaired thought processes and lack of interest in eating or refusal to eat

Expected Outcomes: The patient will maintain adequate food intake and weight within normal limits for height.

Evaluation of Outcomes: Does patient maintain appropriate weight?

Intervention  Monitor intake, weight, and serum albumin. Rationale  Loss of weight or a serum albumin level of less than 3.5 indicates poor nutrition. Evaluation Are weight and serum albumin level stable and within normal limits?

Intervention  Develop meal plan to include likes and dislikes, snacks, and protein supplements as necessary. Rationale  Using the patient’s favorite foods will encourage eating. Evaluation Is patient consuming majority of meals?

Intervention  Offer larger meal when patient has the greatest appetite or serve small meals five to six times a day. Rationale  A lot of food at one time can feel overwhelming to the patient. Evaluation Is patient eating meals that are served?

Intervention  Offer one food at a time if patient is not successful with a whole plate full. Rationale  Too many choices on a plate can feel overwhelming to the patient. Evaluation Does patient eat more if one food at a time is offered?

Intervention  Offer finger foods. Rationale  Utensils can be difficult for the patient to use and can discourage eating. Evaluation Does patient eat more when finger foods are offered?

For additional information, see also “Nutrition Notes.”
### Nursing Diagnosis: Chronic Confusion related to dementia

**Expected Outcome:** The patient will function at optimal cognitive level.

**Evaluation of Outcome:** Is patient maintaining optimum cognitive function?

**Intervention** Monitor changes in thought processes. **Rationale** As cognitive function declines, care plan will need to be revised. **Evaluation** Is patient able to correctly identify objects, remember tasks, speak clearly, identify person, place, and time?

**Intervention** Provide a box of safe, familiar items, such as empty thread spools, or pretty handkerchiefs for women. **Rationale** Patients often rummage through drawers, closets, or boxes. These patients may not recognize the difference between their own possessions and those of others. Keeping them occupied with a box of safe items may decrease their need to look for things. **Evaluation** Does a box of items keep patient occupied and content?

**Intervention** Place calendars, clocks, personal items, and seasonal decorations in patient’s environment. **Rationale** These provide orientation to the present. **Evaluation** Can patient identify the season or year?

**Intervention** If patient hallucinates or has delusions, do not attempt to correct. Focus instead on the feelings related to the hallucinations, such as “Do you feel frightened?” **Rationale** Having feelings validated can help develop trust, while not validating the hallucination. **Evaluation** Does patient respond to refocusing on feelings?

**Intervention** Reduce stressors such as fatigue, overstimulation, or pain. **Rationale** Stress may increase dysfunctional behaviors. **Evaluation** Are stressors eliminated as much as possible? Is patient’s behavior calm?

**Intervention** Maintain patient’s usual routines as much as possible. **Rationale** Familiar routines such as sleeping or eating habits are more comfortable for patients. Change can be stressful. **Evaluation** Are routines organized around the patient rather than the staff?

**Intervention** Communicate clearly. Make eye contact, speak slowly and directly to the patient, use nonverbal gestures. Use a tone of voice conveying respect and sincerity. **Rationale** Unclear communication can increase confusion and stress. Research indicates that the tone of voice plays a role in the ability of the patient to cooperate (Barnes & Brannelly, 2008). **Evaluation** Do all staff members communicate clearly and respectfully with the patient?

**Intervention** Involve family in care planning and implementation. **Rationale** The family knows the patient’s preferences and routines best. **Evaluation** Does family presence help patient stay calm and function at optimum level?

**Intervention** Provide video or audiotapes of patient’s family members. **Rationale** Familiar sounds and pictures can reduce agitation when family is not present. **Evaluation** Do video or audiotapes help calm the patient?

### Nursing Diagnosis: Risk for Caregiver Role Strain related to demands of caring for patient with declining mental status while balancing other demands

**Expected Outcomes:** The caregiver will have support needed to safely manage care of patient. The caregiver will be able to identify when the patient is too difficult to care for and requires more structured observation.

**Evaluation of Outcomes:** Is caregiver managing demands of caring for patient? Is patient safe? Is additional support or a change in environment for patient indicated?

**Intervention** Allow caregiver to verbalize concerns related to burden of caring for patient. **Rationale** An assessment of caregiver concerns and challenges can help the nurse plan appropriate support. **Evaluation** Does the caregiver share concerns? What are the caregiver’s current support systems?
characterized by tremors, changes in posture and gait, rigidity, and slowness of movements. Approximately 50,000 to 60,000 new cases of PD are diagnosed each year in the United States; it ranks 14th in causes of death according to the Centers for Disease Control and Prevention (National Parkinson Foundation, 2013).

Pathophysiology

The substantia nigra is a group of cells located within the basal ganglia, which is situated deep in the brain. These cells are responsible for the production of dopamine, an inhibitory neurotransmitter. Dopamine facilitates the transmission of impulses from one neuron to another. Parkinson’s disease is caused by destruction of the cells of the substantia nigra, resulting in decreased dopamine production. Loss of dopamine function results in impairment of semiautomatic movements. Parkinson’s disease is sometimes referred to as an extrapyramidal disorder because the extrapyramidal tracts in the spinal cord that contain motor neurons are affected.

Acetylcholine, an excitatory neurotransmitter, is secreted normally in individuals with Parkinson’s disease. The normal balance of acetylcholine and dopamine is interrupted in these patients, causing a relative excess of acetylcholine, which results in the tremor, muscle rigidity, and akinesia (loss of muscle movement) characteristic of Parkinson’s disease.

Etiology

The etiology of Parkinson’s disease is unknown. It was first described in 1817 by London surgeon James Parkinson. Although scientists now know that the symptoms are caused by death of dopamine-producing cells in the substantia nigra, they do not know what causes the cells to die. There may be a genetic component, especially in younger patients. Certain environmental toxins can also play a role. Parkinson’s disease–like symptoms, referred to as parkinsonism, can be associated with use of certain drugs, such as phenothiazines. Parkinsonism was also linked to an outbreak of encephalitis in the 1920s.

Signs and Symptoms

The onset of symptoms in patients with Parkinson’s disease is usually gradual and subtle. A substantial percentage of the dopamine-producing cells are nonfunctional before the
Nutrition Notes

Nutrition Issues in Dementia

Efforts are ongoing to identify influences that might delay or mitigate dementia. Preliminary evidence on the role of nutrients in cognitive aging and dementia is fairly strong for protective associations of vitamin E from food, vitamin B₁₂ and folate, DHA (the omega-3 fatty acid found in fish), and a high ratio of polyunsaturated to saturated fats (Morris, 2012). In patients with Alzheimer’s disease, synapse loss is the structural change that correlates most strongly with cognitive impairment. Experimental use of a medical food containing antioxidants promoting synthesis of neuronal membranes improved memory in patients with very mild Alzheimer’s disease (de Wilde, Kamphuis, Sijben, & Scheltens, 2011).

For caregivers of the 4.5 million people in the United States already afflicted with dementia, the immediate problem may be providing the patient with sufficient nutrients. Most commonly, patients with dementia demonstrate a slowing of the swallowing process that may increase time required to finish a meal. They also often have difficulties self-feeding. Both situations increase the risk for malnutrition (Sura, Madhavan, Carnaby, & Crary, 2012). (See Chapter 49, Box 49-2, for dysphagia interventions.)

Dining rooms should be quiet and have adequate lighting. Occupying the same chair for every meal lends familiarity. Serving one course at a time and providing necessary but not extraneous flatware, with large handles if needed, limits distractions. Dishes with high sides enable the patient to scoop the food onto a spoon or fork. Finger foods that the patient can manage may increase intake with minimal staff assistance.

Patients with dementia must be reminded of the steps involved in self-feeding:

• Putting the food on the spoon
• Directing it to the mouth
• Chewing
• Swallowing

Use of verbal cues or guiding the patient’s hand to start the necessary movement helps the process. Common courtesies model social expectations and help maintain a person’s dignity:

• Introducing the patient to the other persons at the table
• Providing a cup rather than a carton for milk
• Offering foods separately rather than mixing them all together.
• Providing color contrast between foods and plate
• Ensuring use of eyeglasses if needed
• Ascertaining favorite foods, especially aromatic ones, to tempt poor eaters
• Playing music with a slow tempo to relax the patient and mask distracting noises

Nearly all patients with advanced dementia develop feeding problems. Health care providers may advise families that high caloric supplements, perhaps in combination with assisted feeding, foods modified in taste or texture, and appetite stimulants can promote weight gain for several months. Given the progressive nature of dementia, families should be counseled not to expect improvements in function or survival with any available form of feeding (Hanson, Ersek, Gilliam, & Carey, 2011).

References

Nearly all patients with advanced dementia develop feeding problems. Health care providers may advise families that high caloric supplements, perhaps in combination with assisted feeding, foods modified in taste or texture, and appetite stimulants can promote weight gain for several months. Given the progressive nature of dementia, families should be counseled not to expect improvements in function or survival with any available form of feeding (Hanson, Ersek, Gilliam, & Carey, 2011).

The primary symptoms of Parkinson’s disease are muscular rigidity, bradykinesia (slow movement) or akinesia, changes in posture, and tremors. The brain is no longer able to direct the muscles to perform in the usual manner. This lack of communication between the brain and the muscles can have a profound impact on the patient’s ability to ambulate safely, perform ADLs and job functions, or enjoy leisure activities. The symptoms may also have a significant negative impact on the patient’s self-esteem.

The patient may have difficulty initiating movement; this can be particularly apparent when the patient tries to start walking, rise from a sitting position, or begin dressing. Because considerable effort is required to move the rigid muscles, the patient performs voluntary movements very slowly. At times, the patient can experience freezing of gait and be unable to initiate ambulation or negotiate a turn during ambulation.

• WORD • BUILDING •

bradykinesia: brady—slow + kinesia—movement
The extensor muscles are more affected by Parkinson’s disease than the flexor muscles. This impaired function of the extensor muscles results in the stooped posture typical of patients with Parkinson’s disease (Fig. 48.14). Flexion of the hips, knees, and neck shifts the center of gravity forward. The gait is characterized by shuffling, short steps that may increase in speed once the patient finally gets walking. Once in motion, the patient may have difficulty stopping. The patient maintains a broad base when making turns to try to compensate for imbalance. These changes place patients at high risk for falls. Slowness of movement and stiff muscles make it much harder for patients to catch themselves if they start to fall or to relax the muscles to minimize injury.

Tremors typically begin in the hand and then progress to the ipsilateral foot. In most patients, the tremor then moves to the contralateral side. Many patients identify one side of the body as being more affected by the tremor than the other. Tremor of the hand has been described as a pill-rolling tremor; the thumb typically moves back and forth across the fingers and looks like the patient is rolling a pill. Tremors typically lessen or disappear during movement and are more noticeable when the extremity is at rest or when trying to hold an object still (this is called a resting tremor). The tremors disappear when the patient is asleep. The inability to hold an object still can make simple acts such as drinking a glass of water or reading a book nearly impossible. The signs and symptoms of Parkinson’s disease tend to increase in severity when the patient becomes fatigued. Another type of tremor, a benign familial (or essential) tremor, can sometimes be mistaken for Parkinson’s disease. Treatment is different for each. See Table 48.11 for differentiation of these tremors.

The secondary symptoms of Parkinson’s disease include generalized weakness, muscle fatigue and cramping, and difficulty with fine motor activities. This fine motor dysfunction can make it difficult for the patient to button a shirt or tie shoes. Handwriting typically deteriorates as the disease progresses. A soft, monotone voice and masklike facial expression can make the patient appear to be lacking in emotional responses. It may be necessary to ask patients about their emotional status and help them develop ways to express their emotions. The normal blink response is diminished, so the patient and significant others must be educated about eye care to prevent corneal abrasions.

Dysfunction of the autonomic system can cause diaphoresis, constipation, orthostatic hypotension, drooling, dysphagia, seborrhea, and frequent urination. Patients who experience seborrhea and diaphoresis need frequent attention to personal hygiene. Drooling and dysphagia can make the patient reluctant to appear in public. Slowness in initiating walking, balance problems, and frequent urination place the patient at risk for urinary incontinence, which can also increase the patient’s reluctance to leave home.

Late in the disease, mental function may become slowed, and the patient may develop dementia. This is compounded by the side effects of many anti-Parkinson’s drugs. Death is usually from complications of immobility.

**Complications**

The most typical acute complications of Parkinson’s disease are related to the patient’s difficulties with mobility and balance.
Patients are prone to falls, which can result in injuries ranging from bruises or fractures to head or spinal cord injuries. Constipation is common because of decreased activity, diminished ability to take in food and fluids, and side effects of anticholinergic medications. Patients are encouraged to increase fiber and fluids in their diets. If constipation is not alleviated by dietary modifications, the patient may need to use stool softeners.

Muscular rigidity and bradykinesia contribute to joint immobility, which decreases patients’ ability to ambulate and care for themselves. Position changes can be painful for patients. A turning sheet and adequate personnel are necessary when turning a patient in bed to prevent stress on the joints. Tremors interfere with ADLs, consume immense amounts of energy, and can prevent the patient from working or performing leisure activities. Swallowing can become so impaired that enteral (tube) feeding is required. Depression is a common complication at any stage of Parkinson’s disease and may compromise communication, ability to learn, and performance of ADLs. Patients may require counseling or antidepressants.

**Diagnostic Tests**

No specific tests are used to diagnose Parkinson’s disease. The diagnosis is based on the history given by the patient and a thorough physical examination. An MRI may be done to rule out alternative causes of the patient’s symptoms.

**Therapeutic Measures**

There is no cure for Parkinson’s disease. Treatment is aimed at controlling symptoms and maximizing the patient’s functional level. Drugs used to control symptoms are listed in Table 48.12.

### Table 48.12 Medications Used to Treat Parkinson’s Disease

<thead>
<tr>
<th>Medication Class/Action</th>
<th>Examples</th>
<th>Nursing Implications</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Cholinergic Blockers</strong></td>
<td>Trihexyphenidyl (Artane), benztrapine (Cogentin)</td>
<td>Monitor I&amp;O for urinary retention. Teach patient not to discontinue abruptly. Implement measures to prevent constipation.</td>
</tr>
<tr>
<td><strong>Dopamine Agonist</strong></td>
<td>Amantadine (Symmetrel)</td>
<td>Use caution with alcohol and other CNS agents.</td>
</tr>
<tr>
<td><strong>Dopamine Agonists</strong></td>
<td>Levodopa (L-dopa), levodopa/carbidopa combination (Sinemet). Carbopida prevents peripheral breakdown of levodopa so more is available in the CNS.</td>
<td>Teach patient to take food shortly after (not before or with) each dose to prevent gastric irritation. May discolor urine and sweat. Teach patient to take ATC to control symptoms.</td>
</tr>
<tr>
<td><strong>Dopamine Agonists</strong></td>
<td>Pramipexole (Mirapex), ropinirole (Requip)</td>
<td>Patients can fall asleep suddenly; caution patient to avoid driving until effects known. Giving with meals may reduce nausea. Caution about drowsiness and sleep attacks (falling asleep during activities that require alertness).</td>
</tr>
<tr>
<td><strong>Monoamine Oxidase B Inhibitor</strong></td>
<td>Selegiline (Eldepryl, Zelapar), rasagiline (Azilect)</td>
<td>Can slow progression of Parkinson’s disease. Administer daily at noon to prevent insomnia. Can cause dangerous interaction with meperidine (Demerol), alcohol, CNS depressants.</td>
</tr>
<tr>
<td><strong>COMT Inhibitor</strong></td>
<td>Entacapone (Comtan)</td>
<td>Report elevated temperature, muscular rigidity, altered LOC, elevated CPK.</td>
</tr>
</tbody>
</table>

*Note.* With all anti–Parkinson’s disease agents, teach patient to check with physician before taking over-the-counter medications, especially cold preparations. Teach to rise slowly to prevent orthostasis. ATC = around the clock; COMT = catechol-O-methyltransferase; CNS = central nervous system. CPK = creatine phosphokinase; I&O = input and output; LOC = level of consciousness.
Many patients with Parkinson’s disease experience fluctuations in motor function related to their drug therapy. This is referred to as the on–off phenomenon. Patients may experience a decreased response to levodopa, or off period, particularly as the dose is wearing off. As the disease progresses, patients may notice that the off periods become less predictable and occur more rapidly. The patient may have a delayed or absent response to the next dose of levodopa, resulting in the patient being stuck in the off stage and being significantly disabled for that period. Fluctuations in motor function can be accompanied by other symptoms, such as pain, diaphoresis, anxiety attacks, hallucinations, or mood swings. These symptoms significantly increase the disability associated with the episodes.

Patients who are taking maximum doses of medication for Parkinson’s disease symptoms may benefit from a “drug holiday.” During a drug holiday, patients are taken off all drugs for a time, then restarted on lower doses. Hospitalization may be necessary during this time to maintain patient safety.

**Surgical Treatments**

Pallidotomy may be an option for patients whose rigidity, tremor, and bradykinesia are uncontrollable by medical management. During this stereotactic procedure, a destructive lesion is placed in the basal ganglia. The surgery is only performed on one side of the brain. The patient remains awake during the surgery to make sure that the lesion is being placed in the appropriate location. These patients need a great deal of education and support before and during the surgery.

Deep-brain stimulation is another surgical treatment, in which a tiny electrode is placed into brain tissue. A generator is then implanted under the skin on the chest, and is connected to the electrode. The generator delivers electrical pulses to the electrode, which may help control symptoms.

Some centers have experimented with implanting stem cells into the brain to develop into dopamine-producing cells; research into gene therapies is also ongoing. These therapies are only experimental at this time. For more information, visit the National Parkinson Foundation at www.parkinson.org.

**Nursing Process for the Patient With Parkinson’s Disease**

**DATA COLLECTION.** Ask the patient about symptoms of Parkinson’s disease and their effect on level of functioning. Observe ability to move, walk, and perform ADLs safely. Determine risk for injury related to immobility or falls. Assess nutritional status and condition of skin. Identify presence of confusion and side effects of medications. Psychosocial assessment includes the patient’s and caregiver’s responses to the disease, coping strategies, and support systems.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.** The patient with Parkinson’s disease is at risk for many problems. Priority diagnoses are addressed below. If confusion is present, also see the “Nursing Care Plan for the Patient With Dementia.”

**Impaired Physical Mobility related to muscle stiffness and tremor**

**EXPECTED OUTCOME:** The patient will maintain optimal mobility and ability to ambulate as long as possible.

- Assist patient to plan daily activities based on anticipated response to medications. Certain times of day may be less troublesome than others.
- Consult with physical and occupational therapists to provide assistive devices to help maintain mobility and provide diversional activities.
- Provide assistance with ROM exercises to maintain flexibility of muscles.
- Teach patients who have difficulty initiating walking to pick up one foot as though attempting to step over something to take the first step. It may also help to take several steps in place before starting to walk. This may help overcome freezing of gait.

**Self-Care Deficit related to reduced mobility**

**EXPECTED OUTCOME:** The patient’s self-care needs will be met as evidenced by patient statement.

- Encourage the patient to participate in ADLs as much as possible. This helps the patient maintain independence and self-esteem.
- Consult occupational therapist to assist with devices and strategies for maintaining independence.
- Instruct the patient or family to provide clothing without buttons and supply shoes with adherent fasteners, rather than shoelaces, to help maintain independence.
- Assist the patient and family to make decisions about long-term care. Consult a social worker as needed for assistance. As the patient ages, so do the significant others who are providing care. The point may be reached at which the caregiver is no longer able to meet the increasing needs of the patient. The decision to place the patient in a skilled nursing facility is extremely difficult and emotional.

**Risk for Injury related to reduced mobility and balance**

**EXPECTED OUTCOME:** The patient will remain safe and without injury.

- If the patient is in the hospital or extended care facility, keep the call light within reach at all times. Remind the patient to request assistance with ambulation. The patient is at risk for injury from falls related to problems with mobility.
- Maintain bed in the low position, with side rails raised if appropriate (side rails may be prohibited in some institutions). Maintaining the bed in a low position reduces the risk for injury or fall when getting out of bed. Side rails can increase the risk for injury, and must be used carefully.
- Use an alarm system that alerts the staff that the patient is getting up so that staff can assist the patient to get up and ambulate.
- Avoid use of restraints. Restraints can increase the risk for injury.
• Keep environment free from clutter, throw rugs, or other items that can cause a patient to trip.
• Provide walkers and other assistive devices to provide support and prevent falls.

EVALUATION. The care of the patient with Parkinson’s disease has been successful if the patient remains as mobile and independent as possible. Self-care needs should be met by the patient or others, and the patient should remain safe from injury.

**CRITICAL THINKING**

**Ms. Simpson**

Ms. Simpson is a 47-year-old Caucasian woman. She has had Parkinson’s disease for the past 5 years, and the symptoms are becoming progressively worse. She is now admitted for a urinary tract infection.

1. What problems do you foresee when caring for Ms. Simpson?
2. What safety measures should you implement?
3. Ms. Simpson is receiving IV fluids of 5% dextrose in 0.45% saline, 1000 mL over 12 hours. The RN on duty is accountable for her IV, but as you are bathing her you notice that the bag is nearly full and it has been hanging for 4 hours. How many milliliters should still be in her IV bag after 4 hours?
4. What members of the health team should you collaborate with in providing Ms. Simpson’s care?

Suggested answers are at the end of the chapter.

---

**Huntington’s Disease**

Huntington’s disease is a progressive, hereditary, degenerative, incurable neurologic disorder. It was first described in 1872 by George Huntington, a general practitioner in New York. The uncontrolled movements associated with Huntington’s disease caused some sufferers in the 17th century to be accused of and executed for witchcraft. Many of the cases around the world can be traced back to specific individuals.

**Pathophysiology and Etiology**

Huntington’s disease (also known as Huntington’s chorea) is inherited in an autosomal dominant manner which means that each offspring of an affected parent has a 50% chance of inheriting the disorder. A mutation in a specific gene has been identified; however, the cause of the mutation is not known. According to a study completed recently at Johns Hopkins in Baltimore, Maryland, a protein called rhes may be responsible for the activation of a mutant protein that causes destruction of the cells in the corpus striatum (Saey, 2009). Destruction also occurs in the caudate nucleus and other deep nuclei of the brain and portions of the cerebral cortex. This degeneration results in progressive loss of normal movement and intellect. The rate of disease progression varies from person to person.

**Signs and Symptoms**

Signs and symptoms usually begin in middle age and develop slowly, becoming progressively more apparent. Cognitive signs can be noticed before movement problems. Patients who are not aware of their hereditary risk for Huntington’s disease may be incorrectly diagnosed as being mentally ill.

The patient can display personality changes and inappropriate behavior. The patient may be euphoric or irritable and can rapidly alternate between moods. Paranoia is common, and behavior can become violent as dementia worsens. The patient eventually progresses to the point at which he or she is incontinent and totally dependent on others for care. These symptoms are difficult for family and friends as well as professional caregivers to cope with. The disease progression and associated symptoms are particularly devastating for offspring, who may or may not know whether they have inherited the disease.

Physical symptoms also develop slowly. Huntington’s disease is characterized by involuntary, irregular, jerky, dancelike (choreiform) movements. Initially these symptoms can take the form of mild fidgeting and facial grimacing. In the early stages of the disease, the patient may try to cover the movements by incorporating them into a voluntary movement such as crossing the arms or scratching. The involuntary movements usually start in the arms, face, and neck and progressively involve the remainder of the body. Patients display hesitant speech, eye blinking, irregular trunk movements, abnormal tilt of the head, and constant motion (Fig. 48.15). The gait is wide, and the patient may appear to be dancing. Emotional upset, stress, or trying to perform a voluntary task can significantly increase the severity and rate of the abnormal movements; the movements typically diminish or disappear during sleep. Dysphagia can significantly impair the patient’s nutritional status.

Depression and suicide are common in the earlier stages of the disease, when the patient still has the cognitive ability to carry out a suicidal act. As the disease progresses, the patient becomes more and more dependent. Aspiration resulting in respiratory failure is the primary cause of death. Life span following diagnosis is about 10 to 30 years.

**Diagnostic Tests**

Huntington’s disease has typically been diagnosed based on the clinical examination and a family history of the disease. MRI or CT may be helpful. Genetic testing is a viable option for prenatal use and to determine if an individual has Huntington’s disease before he or she becomes symptomatic. This is important because Huntington’s disease does not become symptomatic until patients are in their 30s or 40s, when they may already have children who could be affected (see “Patient Perspective”).
Patient Perspective

Betty

I was born the second of six children. My mom was diagnosed with Huntington’s chorea (an old name for Huntington’s disease) after she had all of us. My brother was diagnosed with Huntington’s disease at the age of 60. He started out with terrible mood swings and a bad temper, but eventually he had a lot of movement problems, including pronounced facial and tongue movements.

By the time we knew the disease had affected our family, many of us had children and grandchildren of our own. My kids wanted me to be tested. It is a hereditary disease and you have a 50/50 chance of having it if a parent has it. If I had Huntington’s, then my kids would have a 50/50 chance of having it. If I tested negative, then they and their children would not be at risk.

I was very nervous and afraid of being tested. When I went for the initial visit at the University of Michigan, they observed my movements, how I walked and talked, and my facial movements. They made me go to a psychologist to see if I could handle the results if they did the blood test that would tell for sure. I understand the suicide rate is kind of high for people with Huntington’s. After talking for an hour and a half, they decided I could handle the results.

At my next visit, they just drew blood, which was sent out for testing. I had to return to the university 6 weeks later for the results. When I went back, I was a nervous wreck. A friend went with me. When the technician came in, she said the doctor would be with me soon. I immediately had bad thoughts. Then when the technician and doctor came back, they were both smiling and had tears in their eyes—I had tested negative. So my friend, the doctor, the technician, and I all hugged and cried.

It is a very hard disease to live with, whether you or another family member has it. My brother has it very bad. Out of my five siblings, four have it for sure, and we think the fifth has it because of mood swings we have observed.

I am the only one of the six who tested clear. I felt very guilty at first that they all had it and I didn’t. I’m starting to get over that, but when I see one of them having a bad time with talking, or temper, or movement, the guilt starts to kick in again.

Therapeutic Measures

Because there is no cure, treatment of Huntington’s disease focuses on minimizing symptoms and preventing complications. Antipsychotic, antidepressant, and antichoreic drugs may be used to treat both the involuntary movements and behavioral outbursts. A new medication, tetrabenazine (Xenazine), may help reduce involuntary movements by increasing dopamine in the brain. Physical and occupational therapy can help keep the patient mobile and independent for as long as possible. Research has been done on the benefits of transplanting stem cells into the brains of patients with Huntington’s disease, but this is still experimental at this time.

Nursing Care

Patients with Huntington’s disease are typically cared for on an outpatient basis. When a patient with Huntington’s disease is admitted to an inpatient facility, it is important to obtain as much information as possible about that person’s response to medication, daily routine, and emotional and cognitive functioning from the caregivers. For example, knowing that a certain patient is intensely afraid of bathtubs but willingly takes showers can prevent unnecessary struggles and outbursts. Providing some objects from home can make the new environment seem less threatening. The caregivers may relate that the patient has better cognitive functioning at a particular time of day. As the dementia progresses, the patient responds less
to attempts at reasoning. Giving directions in a calm but firm tone may help the patient cooperate with activities. The environment should be modified to keep the patient safe. Keep in mind that forceful, involuntary movements of the patient’s extremities can happen at any time and should not be misinterpreted as an attempt to harm caregivers.

Difficulty swallowing typically begins toward the middle of the disease course. Patients exhibit trouble swallowing liquids in particular. At this stage, it may still be possible to teach the patient to hold the chin down to the chest while swallowing, which lessens the chance of aspiration. Have patients sit straight upright while eating. Thickening agents can be added to thin liquids to help prevent aspiration. Adaptive devices can prolong the patient’s ability to eat independently. Soft foods that are easily manipulated in the mouth are most suitable. These patients may have difficulty taking in adequate calories to maintain a normal body weight, even if a caregiver assists with feeding them. One of the many ethical issues faced by these patients and their significant others is whether artificial feeding should be used and, if so, for how long. Patients and their significant others should be encouraged to discuss end-of-life decisions early in the course of the disease.

Also see the “Nursing Care Plan for the Patient With Dementia.”

Alzheimer’s Disease

Alzheimer’s disease (also called dementia of the Alzheimer’s type [DAT]) is the most common of several types of dementia. Dementia is a progressive loss of mental functioning that interferes with memory, ability to think clearly and learn, and eventually ability to function (see discussion of dementia earlier in this chapter).

Alois Alzheimer, a German neurologist, first described the disease in 1907. He described pathological changes, now referred to as neurofibrillary tangles and neuritic plaques, that he discovered while performing an autopsy on a patient with dementia. Alzheimer’s disease is a progressively degenerative disease that is inevitably fatal. The incidence of Alzheimer’s disease is more common in women than men and doubles for every 5 years a person lives beyond age 65.

Etiology and Pathophysiology

Many etiologies have been theorized for Alzheimer’s disease, including viral or bacterial infection and autoimmune dysfunction. Markers associated with Alzheimer’s disease can be found on several chromosomes. Chromosome 21 in particular has been associated with Alzheimer’s disease, and is also the location of the genetic abnormality responsible for Down syndrome. Patients older than age 40 who have Down syndrome usually develop Alzheimer’s disease. The exact correlation between the two disorders is still being studied. Lifestyle factors that increase risk of Alzheimer’s disease include hypertension, hypercholesterolemia, and poorly controlled diabetes.

Although the exact cause of Alzheimer’s disease is unknown, the structural changes associated with it have been well documented. An abnormality exists within the protein of the cell membrane of a neuron. As the axon terminals and dendrite branches disintegrate, they collect in neuritic plaques. Inside the normal brain is a precise arrangement of filaments and tubules that are responsible for cell integrity. Individuals with Alzheimer’s disease develop neurofibrillary tangles instead of the normal orderly arrangement. Instead of remaining a small area of abnormality, these neuritic plaques and neurofibrillary tangles spread via axons to other areas of the brain. In addition, patients tend to have a deficiency of acetylcholine in the cerebral cortex. Remember that acetylcholine is a neurotransmitter important for nervous system function.

Advancement of neurofibrillary tangles and neuritic plaques typically affects the hippocampus first, resulting in short-term memory dysfunction. As the tangles and plaques spread to the temporal lobe, the memory impairment becomes more severe. It may be at this point that the patient accesses the health care system. Personality changes and incontinence are inevitable results of Alzheimer’s disease. These symptoms can be attributed to the spread of plaques and tangles to the frontal lobes of the brain.

It is believed that the younger the patient is at the time of onset, the faster the neurofibrillary tangles and neuritic plaques spread. Therefore, these patients tend to deteriorate faster, require complete care earlier, and have a shorter life span.

One area of the brain that is left relatively untouched by Alzheimer’s is the subcortical area. This structure is responsible for our subconscious urge to survive. The needs for basic requirements such as shelter, food and water, security, and reproduction are controlled by the subcortical area, as are emotional responses to situations. The patient with Alzheimer’s disease may experience hunger but no longer know how to meet that basic need. Left to their own devices, these individuals would starve.

Signs and Symptoms

The signs and symptoms of Alzheimer’s disease are typically broken down into three stages.

ALZHEIMER’S STAGE 1. The early stage, stage 1, lasts from 2 to 4 years and is characterized by increasing forgetfulness. At this stage, the patient may attempt to cope by using lists and reminders. Interest in day-to-day activities, acquaintances, and surroundings tends to diminish. The patient is reluctant to take on tasks because of uncertainty in how to perform them. If the patient is still working, his or her performance deteriorates and can result in being terminated from the job.

ALZHEIMER’S STAGE 2. The middle stage, stage 2, is the longest in duration, lasting 2 to 12 years. Progressive cognitive deterioration causes difficulty doing simple calculations or answering questions. Patients may become irritable, particularly when asked to perform a task that they know they should be able to perform but cannot. It may help the patient to break down the task into manageable steps. Depression is common. Aphasia and the resulting inability to make
themselves understood can exacerbate patients’ irritability. It is during the middle stage, as cognitive function significantly deteriorates, that the patient may become more physically active. The normal sleep–wake cycle is disrupted, and the patient tends to wander aimlessly, particularly at night. The patient may become lost in familiar surroundings, which compounds the anxiety that typically develops during this stage. Hallucinations and seizures can occur. Management of day-to-day activities such as feeding a pet or paying bills becomes overwhelming. Personal hygiene deteriorates, as does appropriate social behavior. Patients may make up stories to cover for deficits, saying that possessions they misplaced were stolen. Some patients hoard food or money.

**ALZHEIMER’S STAGE 3.** The third stage of Alzheimer’s disease is characterized by progression to complete dependency. The patient loses the ability to converse or control bowel or bladder function. If the patient is still mobile, constant supervision is required to protect from wandering and avoid injury. Emotional control and the ability to recognize significant others are lost. This lack of recognition is particularly devastating for family members. Eventually the patient is unable to move independently, swallow, or express needs. Death usually occurs from complications of immobility.

The duration of the final stage of Alzheimer’s disease, characterized by complete dependence, depends in part on the physical stamina and general health of the individual. The healthier the patient, the longer the body will continue to function. Another factor is the decisions that have been made regarding artificial feeding and respiratory support. Few significant others or HCPs advocate intubation and mechanical ventilation for patients with Alzheimer’s disease. The issue of enteral (tube) feedings, however, is an emotional one with few easy answers. The use of enteral feedings can prolong the patient’s life, despite the absence of cognitive functioning. As with patients suffering from Huntington’s disease, every effort should be made to determine the patient’s wishes before cognitive impairment makes that impossible. See Table 48.13 for a comparison of the symptoms of Parkinson’s, Huntington’s, and Alzheimer’s diseases.

### Diagnostic Tests

The only absolute method of confirming a diagnosis of Alzheimer’s disease is by pathological examination at autopsy. In actuality, the disease is diagnosed on the basis of clinical examination, history, and elimination of other possible causes of the symptoms. MRI can reveal the presence of classic neurofibrillary tangles and neuritic plaques. Positron emission tomography (PET) and single photon emission computed tomography (SPECT) scans show areas of neuronal inactivity. A recent study by Roe et al (2013) found biomarkers that can predict the risk of Alzheimer’s disease using brain imaging and spinal-fluid testing. It is also thought that these biomarkers may be able to be used to test new treatments for efficacy in controlling the onset of the disease.

### Therapeutic Measures

There is no known cure for Alzheimer’s disease. Treatment has traditionally focused on minimizing the effects of the disease and maintaining independence as long as possible. Acetylcholinesterase (AChE) inhibitors such as donepezil (Aricept) or rivastigmine (Exelon) are thought to inhibit the breakdown of the neurotransmitter acetylcholine (see Table 48.10). Increased levels of acetylcholine in the brain allow for better functioning of the remaining neurons. They appear to be most effective for those patients who exhibit mild to moderate symptoms of Alzheimer’s disease. It can take some time to notice any effects of the drugs. Use of AChE inhibitors diminishes the amount of medical care and social service interventions required and delays admission to skilled nursing facilities. This delay in institutionalization can result in significant positive impact on quality of life, as well as financial savings for the patient and family.

Another class of medications, NMDA (N-methyl-D-aspartate) antagonists, can prevent overexcitation of NMDA

| **TABLE 48.13** COMPARISONS OF PARKINSON’S DISEASE, HUNTINGTON’S DISEASE, AND ALZHEIMER’S DISEASE |
|---------------------------------|----------------|----------------|----------------|
| **Symptom**                     | Parkinson’s Disease | Huntington’s Disease | Alzheimer’s Disease |
| Tremors                         | Present           | Absent           | Absent         |
| Bradykinesia/akinesia           | Present           | Absent           | Absent         |
| Muscle rigidity                 | Present           | Absent           | Absent         |
| Memory dysfunction              | Late              | Early            | Late           |
| Cognitive dysfunction           | Late              | Early            | Present        |
| Inability to perform ADLs       | Progressive       | Progressive      | Progressive    |
| Involuntary movements           | Absent            | Absent           | Present        |
| Depression                      | Present           | Present          | Present        |
receptors in the brain and allow more normal function. Memantine (Namenda, Axura) is the only drug currently available in this class. These drugs can be given at any stage of Alzheimer’s disease and, like AChE inhibitors, simply slow the patient’s decline.

Antidepressants, antipsychotics, and antianxiety drugs can be used as a last resort to control symptoms of depression and behavioral disturbances, but they do not treat the dementia. Patients should be carefully monitored for drug interactions and side effects. For more information, visit the Alzheimer’s Association at www.alz.org.

Nursing Process for the Patient With Alzheimer’s Disease

See the earlier discussion of dementia and the “Nursing Care Plan for the Patient With Dementia.”

CRITICAL THINKING

Mrs. Johnson

Mrs. Johnson has just become a resident at the Valley Bend extended care facility. She is diagnosed with Alzheimer’s disease and is in the second stage with some signs of stage 3 disease. When you check on her during the evening, you find her walking around her room, talking to herself. What other signs and symptoms are typical for stage 2 and stage 3 Alzheimer’s disease? How should you address her behavior?

Suggested answers are at the end of the chapter.

Home Health Hints

To assess a patient’s neurologic status at home:

• Note whether the patient’s clothes are matched and properly fastened. Is the patient clean and well groomed?

SUGGESTED ANSWERS TO CRITICAL THINKING

Mr. Chung

1. Be prepared to assist with a lumbar puncture.
2. You should use short, simple sentences because he may be very anxious or disoriented. Involve his family. Further education can be provided when he is feeling better.

3. Because meningococcal meningitis is contagious, he should be placed in isolation. Gloves, gowns, and masks should be used. Explain the need for these practices to Mr. Chung and his visitors.

4. Comfort measures include tepid baths, a quiet, dark environment, and minimal stimulation. Administer acetaminophen and analgesics as ordered.
5. The health service at his college should be notified of his diagnosis. Close contacts may require prophylactic treatment. If Mr. Chung lives at home rather than at college, his family members should be advised to see their HCP and begin prophylactic treatment.

**Mr. Evans**

1. You might expect to see impaired speech, right-sided weakness, and a rapid decrease in consciousness if Mr. Evans’ hematoma is enlarged.

2. Intubation equipment, mannitol, and IV access should be ready. He should be given nothing by mouth (NPO) and the results of laboratory tests should be ready in the event of emergency surgery. The location of Mr. Evans’ next of kin must be known.

3. Who are Mr. Evans’s support people? Was this drinking episode an isolated incident or a chronic problem that should be addressed if he is discharged safely?

4. Health team members needed for Mr. Evans depend on the extent of his injury and include a social worker; physical, occupational, and speech therapists; neuropsychologist; dietitian; and others.

**Ms. Simpson**

1. Urinary tract infection is often accompanied by urinary urgency. Ms. Simpson may have difficulty getting to the bathroom quickly and safely.

2. Keep a bedside commode nearby if the bathroom is not close. Assist Ms. Simpson to the bathroom or commode at regular intervals to prevent urgency. Remind her to ask for help if she needs to get up. Make sure that her call light is within reach.

3. \[
\frac{1000 \text{ mL}}{12 \text{ hours}} \times \frac{4 \text{ hours}}{4 \text{ hours}} = 333 \text{ mL}
\]

After 4 hours: 1000–333 mL = 667 mL should remain in the bag. Because it is still nearly full, the RN should be notified.

4. Occupational, physical, and speech therapy may be involved in Ms. Simpson’s care. Speech therapy can help with swallowing problems. Work with nursing assistants to be sure she is mobilized and protected from falls.

**Mrs. Johnson**

Being admitted to a new and unfamiliar facility can increase confusion. Signs of second-stage Alzheimer’s disease include memory loss, wandering at night, sleeplessness, irritability, loss of way in familiar surroundings, losing possessions and searching for them, and neglect of personal hygiene. During the third stage of the disease, the patient will lose weight, recognize hunger but be unable to eat, be unable to communicate verbally or in writing, lose ability to recognize family, become incontinent of urine and feces, and eventually lose ability to stand and walk. Address Mrs. Johnson by her name and ask her what she needs. Reorient her to where she is and assure her that she is safe and being cared for.

**REVIEW QUESTIONS**

1. A college student is admitted to the hospital with a severe headache. Which finding in the student’s history is consistent with the diagnosis of meningitis?
   1. A sore throat for 3 days
   2. A family history of migraine headaches
   3. A muscle injury in the neck
   4. A recent motor vehicle accident

2. A patient with meningitis has photophobia and a severe headache. Which nursing interventions will be most helpful to relieve symptoms?
   1. Administer antibiotics as ordered, and prepare the patient for a lumbar puncture.
   2. Darken the room and administer analgesics.
   3. Administer acetaminophen as ordered and maintain isolation.
   4. Check level of consciousness with the Glasgow Coma Scale and monitor vital signs.

3. A patient makes an appointment to see a primary care practitioner for recurrent severe headaches. Which instruction by the nurse will help gather the best additional data before the appointment?
   1. “Try relaxation and warm moist compresses for your headaches and document your response.”
   2. “Call and come in the next time you have a headache so you can be examined.”
   3. “Keep track of how many headaches you have before you come in.”
   4. “Keep a diary of your headaches, recording symptoms, timing, and headache triggers.”
4. A patient who has had a generalized tonic-clonic seizure is sound asleep 30 minutes after the seizure. Meals are about to be delivered. Which nursing action is most appropriate? 
   1. Wake the patient because nourishment is essential following a seizure.
   2. Wake the patient to do a neurologic assessment before the meal.
   3. Let the patient sleep during the postictal state, and keep the meal warm.
   4. Do not attempt to wake the patient because of the risk of a repeat seizure.

5. A patient with a history of seizures reports experiencing an aura and is concerned about an impending seizure. Place the nurse’s interventions in the correct order. 
   1. Protect the patient from injury during the seizure.
   2. Document the events of the seizure.
   3. Help the patient lie down in a safe place.
   4. Turn the patient on his or her side to sleep.

6. Which patients should be closely monitored by the nurse for symptoms of increased intracranial pressure? Select all that apply.
   1. The patient who has a history of epilepsy
   2. The patient admitted with a high fever and severe headache
   3. The patient in the postanesthesia care unit following craniectomy
   4. The patient with a brain tumor who is admitted for radiation therapy
   5. The patient with a history of migraine headaches, admitted for orthopedic surgery
   6. The patient with Alzheimer’s disease admitted with a urinary tract infection

7. Which of the following actions should the nurse take to help prevent increased intracranial pressure in a patient following a traumatic brain injury? 
   1. Cluster care so the patient can have long periods of rest.
   2. Keep the head of the bed elevated at 30 degrees.
   3. Suction frequently to keep the airway clear.
   4. Do not give anything by mouth.

8. A patient is admitted following a T4 spinal injury. When taking morning vital signs, the nurse notes that the patient appears restless and the blood pressure is elevated. Which of the following actions by the nurse is appropriate? 
   1. Recheck the patient’s blood pressure in 30 minutes.
   2. No action is necessary. This is an expected finding.
   3. Check for a full bladder or bowel.
   4. Encourage the patient to express any anxiety.

9. Which nursing interventions are appropriate for the patient with a neurodegenerative disorder who has difficulty swallowing? 
   1. Have the patient tuck his or her chin down during swallowing.
   2. Provide clear to full liquids; avoid solid foods.
   3. Place the patient in semi-Fowler’s position for eating.
   4. Provide adaptive eating utensils.

10. A resident of an extended care facility who has Alzheimer’s disease is sitting in a corner, crying loudly that no one is paying attention. Several staff members have tried to find out what’s wrong, but the patient won’t answer, and just keeps rocking back and forth and crying. Which approach by the nurse might best help the patient? 
   1. Say in a quiet voice, “What is wrong? We can’t help you if you don’t tell us what’s wrong.”
   2. Sit quietly by the patient and say, “I’m here; you aren’t alone.”
   3. Say in a firm voice, “Several staff members have asked what you need. Now it is time to stop crying.”
   4. Ignore the continued crying. Continuing to respond will encourage the behavior.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Describe the causes, risk factors, and pathophysiology of transient ischemic attack, ischemic stroke, and hemorrhagic stroke.
2. Identify emergency interventions for transient ischemic attack, ischemic stroke, and hemorrhagic stroke.
3. Plan therapeutic measures for transient ischemic attack, ischemic stroke, and hemorrhagic stroke.
4. Identify outcomes that can be expected for a stroke victim.
5. Plan nursing care for a patient with a cerebrovascular disorder.

KEY TERMS

aphasia (uh-FAY-zhuh)
ataxia (ah-TAK-see-ah)
diplopia (dip-LOH-pee-ah)
dysphasia (dis-FAY-zhah)
embolic (em-BOL-ik)
embolism (EM-buh-lizm)
endarterectomy (end-AR-tur-EK-tuh-mee)
hemiplegia (HEM-ee-PLEE-jee-ah)
hemorrhagic (hem-uh-RAH-jik)
intracerebral (IN-trah-sur-EE-brul)
ischemic (i-SKEE-mik)
penumbra (puh-NUM-brah)
thrombolytic (throm-buh-LIT-ik)
thrombosis (throm-BOH-sis)
thrombotic (throm-BOT-ik)
Cerebrovascular disorders occur when the supply of blood and oxygen to brain cells is inadequate, allowing brain tissue to die, and causing a cerebrovascular accident (stroke). The most common cerebrovascular disorders include transient ischemic attack, ischemic stroke, and hemorrhagic stroke.

**TRANSIENT ISCHEMIC ATTACK**

A transient ischemic attack (TIA) is a temporary blockage of blood to the brain that causes a transient (brief) neurologic impairment. The episode typically lasts minutes to hours, and the patient recovers completely. The risk factors, causes, and symptoms of a TIA are identical to those of a cerebrovascular accident (CVA), commonly known as a stroke. Indeed, if the blockage that causes a TIA does not reverse, an area of the brain is permanently damaged, and the event is a stroke. About 15% of all strokes are preceded by a TIA (American Stroke Association, 2013). Urgent evaluation of a TIA is essential to decrease the risk of stroke.

Treatment of a TIA is focused on preventing a full stroke. The cause of the TIA may be discovered with diagnostic tests, which can then guide treatment. However, there may be no clear etiology of the TIA. Treatment, therefore, is mostly centered on minimizing the patient's risk factors for a stroke.

**STROKE (CEREBROVASCULAR ACCIDENT)**

A stroke is caused by the disruption of blood flow to the brain, resulting in death of brain cells. In most cases, permanent disability results. A stroke is more likely to happen as one ages; about 795,000 people of all ages are affected each year. Because of their increased longevity, 60,000 more women have strokes each year than men. Stroke is our nation’s number four cause of death and the leading cause of disability African Americans, Hispanic Americans, American Indian/Alaska Natives, and multiracial people are at higher risk than non-Hispanic whites (American Heart Association [AHA], 2013). There is also a higher incidence of stroke in people with lower levels of education, lower socioeconomic status, and those living in the southeastern United States.

**Pathophysiology**

Cerebral function depends on oxygen and glucose delivery to neurons in the brain. The brain cannot store oxygen or glucose, so it relies on a constant supply of these nutrients. If the supply of oxygen and glucose is stopped, brain tissue dies. When a stroke occurs, brain cells begin dying immediately. There is an area of brain tissue surrounding the damage, called the penumbra, which contains brain cells that are “stunned” and can be revived if the brain is reperfused quickly. However, they will die if the blood supply is not restored.

The particular vessel or vessels involved determine the area of the brain affected and the symptoms that result. The duration of ischemia determines whether the symptoms are transient or permanent. TIA symptoms generally resolve within 24 hours; however, a TIA can be a warning of an impending stroke.

**Etiology**

Strokes are classified as either ischemic or hemorrhagic. Ischemic strokes are more common, accounting for about 87% of all strokes (AHA, 2013). Hemorrhagic strokes account for the remaining 13% of strokes.

**Ischemic Stroke**

Ischemic stroke occurs when the blood supply to the brain is blocked or significantly slowed. It can be one of two major types: thrombotic or embolic (Fig. 49.1).

**THROMBOTIC STROKE.** Thrombotic strokes occur when an occlusion builds up in an artery until it significantly decreases or stops blood flow to the brain. Thrombotic strokes most often occur in the internal or common carotid arteries.

**EMBOLIC STROKE.** An embolic stroke is typically caused by a blood clot that is created somewhere in the body, often within the heart, and travels through the arteries until it becomes trapped in a smaller vessel, preventing the passage of blood. Typically, the embolism will travel and become lodged in the middle, anterior, or posterior cerebral arteries.

**Risk Factors**

Risk factors for ischemic stroke are classified as modifiable or nonmodifiable (Box 49.1). Nonmodifiable risk factors are those that cannot be altered, such as age or gender. Modifiable risk factors are those that can be changed with treatment, such as high blood pressure. Women have additional risks due to hormone changes in pregnancy and menopause. Children with sickle cell disease, cardiac anomaly, and hyperlipidemia are also at risk for stroke. Minimizing or eliminating these modifiable risk factors can significantly lower risk of a stroke. See Fig. 49.2, Stroke Risk Scorecard, to find out your risk for stroke.

**Hemorrhagic Stroke**

Hemorrhagic strokes are caused by the rupture of a cerebral blood vessel that allows blood to escape into brain tissue and not travel beyond the point of the rupture. It can be further classified into two major types: subarachnoid hemorrhage and intracerebral hemorrhage.

**NURSING CARE TIP**

Print the Stroke Risk Scorecard from DavisPlus and keep it in your pocket for patient teaching opportunities.
Chapter 49  Nursing Care of Patients With Cerebrovascular Disorders

Very serious and require surgery to correct. They are often fatal.

**INTRACEREBRAL HEMORRHAGE.** This type of stroke occurs in the deeper tissues of the brain and is usually caused by uncontrolled hypertension. Patients can experience multiple undetected intracerebral hemorrhages, with minimal deficits noted. However, damage will eventually accumulate and the patient will develop major deficits. Maintaining blood pressure below 120/80 mm Hg should be the goal for these patients. (More specific information related to special care of patients with hemorrhagic strokes will be addressed later in the chapter.)

**Warning Signs of Any Type of Stroke**

Patients and family members should be taught to recognize signs and symptoms and how to activate emergency medical services (EMS) if these signs occur. There is evidence that if treatment begins within 1 hour of the onset of symptoms, permanent loss of function can be avoided or minimized.

The acronym FAST can be used to teach emergency triage nurses, first responders, nonlicensed personnel, and community members to recognize a stroke and respond quickly. Time is extremely important to preserve brain cells. Quick access to the EMS system is of particular importance. Research has shown that patients arriving by ambulance are admitted to an emergency department (ED) and evaluated faster than those who “walk in” on their own. Those arriving by ambulance are also more likely to arrive within 2 hours of symptom onset (Table 49.1).

In addition to FAST, the following five signs or symptoms recognized by the American Heart Association and American Stroke Association require immediate EMS activation:

- Sudden numbness or weakness of face, arm, or leg, especially on one side of the body
- Sudden confusion or trouble speaking or understanding
- Sudden trouble seeing in one or both eyes
- Sudden trouble walking, dizziness, loss of balance, or coordination
- Sudden severe headache with no known cause (American Stroke Association, 2013).

Women have other unique symptoms such as sudden onset of:

- Nausea
- Facial and limb pain
- General weakness
- Chest pain
- Shortness of breath
- Hiccups
- Palpitations (Ennen, 2013)

**SUBARACHNOID HEMORRHAGE.** This type of stroke occurs on the surface of the brain and is most often the result of a ruptured cerebral aneurysm (covered later in this chapter). Strokes caused by subarachnoid hemorrhage usually are...
### Stroke Risk Scorecard

Each box that applies to you equals 1 point. Total your score at the bottom of each column and compare with the stroke risk levels on the back.

### Risk Scorecard Results

- **High Risk $\geq 3$:** Ask about stroke prevention right away.
- **Caution 4-6:** A good start. Work on reducing risk.
- **Low Risk 6-8:** You’re doing very well at controlling stroke risk!

**Ask your healthcare professional how to reduce your risk of stroke.**

**To reduce your risk:**
1. Know your blood pressure.
2. Find out whether you have atrial fibrillation.
3. If you smoke, stop.
4. Find out if you have high cholesterol.
5. If diabetic, follow recommendations to control your diabetes.
6. Include exercise in your daily routine.
7. Enjoy a lower-sodium (salt), lower-fat diet.

**Act FAST and CALL 9-1-1 IMMEDIATELY at any sign of a stroke:**

**FACED:** Ask the person to smile. Does one side of the face droop?

**ARMS:** Ask the person to raise both arms. Does one arm drift downward?

**SPEECH:** Ask the person to repeat a simple phrase. Is their speech slurred or strange?

**TIME:** If you observe any of these signs, call 9-1-1 immediately.

---

Acute Signs and Symptoms

Most patients with stroke symptoms present with sudden or rapidly evolving symptoms. Symptoms are varied and depend on the area of the brain affected (Table 49.2). Common symptoms include visual disturbances, language disturbances, weakness or paralysis on one side of the body, and difficulty swallowing (dysphagia). Signs and symptoms are generally the same for both ischemic and hemorrhagic stroke. Patients may have drowsiness and a severe headache, often described as “the worst headache of my life.”

Language Disturbances

Difficulty with language is commonly associated with a TIA and stroke. Aphasia refers to the absence of language; dysphasia refers to difficulty with speech and is not as severe as aphasia. The patient may experience trouble selecting the correct words, use incomprehensible or nonsense speech, have trouble understanding others’ speech, and have trouble writing or reading. Aphasia can be expressive, in which the patient knows what he wants to say but cannot speak or make sense, or receptive, with an inability to understand spoken and/or written words. When both expressive and receptive aphasia are present, it is called global aphasia. Slurred or indistinct speech because of a motor problem (lack of coordination) is referred to as dysarthria. This speech impairment is often the cause of delay in treatment and emphasizes the importance of observation of symptoms by others.

Motor Disturbances

Motor disturbances include paralysis, weakness, and numbness. Sometimes the first evidence of paralysis or weakness is clumsiness or a feeling of heaviness in a limb. The onset will be sudden and typically involves one side of the body—the side opposite the damaged area of the brain. Deficits can appear on both sides of the body if the patient has had a brainstem or vertebrobasilar stroke.

Most commonly, paralysis or weakness affects the arm and face together. Some patients present with complete hemiparesis, with one entire side of the body flaccid. Ataxia may be present, which is poor balance or a stumbling, staggering gait. This can be related to damage to the cerebellum or to poor coordination due to weakness or paralysis. If the swallowing muscles are affected, the patient will have trouble swallowing (dysphagia).

BE SAFE!

BE VIGILANT! Before giving a patient with a suspected stroke anything to eat or drink, including medications, the patient should pass a swallow (dysphagia) screening test to prevent possible aspiration. Evaluate the patient’s facial features and, if there is any apparent weakness or asymmetry, stop and do not give the patient anything by mouth. If no weakness is evident, have the patient swallow about 30 mL of water. If the patient coughs, has difficulty swallowing, or has a wet or gurgly voice afterward, keep the patient NPO (nothing by mouth) until evaluated and cleared by a physician or speech and language pathologist.

Visual Disturbances

Visual field disturbances are also a common symptom of a stroke. The vision loss is painless and can involve loss of all or part of the vision in one eye. Patients often describe the change as a curtain dropping, as fog, or as a gray-out or blackout of vision. The involved eye is on the same side as the diseased artery. Potential visual field abnormalities are shown in Figure 49.3. When you are assessing the patient, stop talking and keep moving across the room. If the patient’s eyes do not follow you, there is a good chance he or she has a deficit in that visual field.

Diagnostic Tests

On arrival at the ED, a computed tomographic (CT) scan will be performed immediately. The purpose of the CT scan is to identify whether symptoms are caused by a hemorrhagic stroke so that the health care provider (HCP) can determine the appropriate course of treatment. Ischemic stroke changes will not be visible on a CT until several days after the event. Interventions for hemorrhagic strokes are different than for ischemic strokes. Care for hemorrhagic strokes is discussed later in this chapter.

After the CT scan, patients may have an electrocardiogram (ECG) to determine if atrial fibrillation is present. An echocardiogram may be done to determine the presence of other heart disease that increases the risk of thrombus formation. Other tests that may be performed in the ED include complete blood count (CBC), blood glucose level, metabolic panel, blood typing, prothrombin time (PT), international normalized ratio (INR), and serum pregnancy, if indicated. Stools and emesis may be checked for blood if indicated. The patient will be placed on a cardiac monitor and pulse oximeter. The ED nurse will complete a dysphagia screen before the patient consumes anything.

ED staff may complete the National Institutes of Health Stroke Scale (NIHSS) to determine the patient’s neurologic deficit level. This 11-point scale determines the severity of a stroke. Nurses can be specially trained and certified to use it. Find out more about the NIHSS at www.nihstrokescale.org.

Once the patient is stabilized, additional tests can be done. Carotid Doppler testing uses ultrasound to detect stenosis of the carotid arteries. Carotid angiography can be done to further determine degree of blockage and help guide treatment.

Therapeutic Measures

Initial emergency care is supportive while test results are pending. ABCs (airway, breathing, and circulation) are monitored. Oxygen is administered if oxygen saturation is less than 92% and the patient’s level of consciousness (LOC) is reduced. Vital
signs and heart rhythm are monitored. A temperature greater than 99.6°F is treated because hyperthermia is associated with poorer outcomes. If intravenous (IV) fluids are needed, only solutions without glucose, such as normal saline solution, are used to prevent hyperglycemia. When test results verify whether the stroke is hemorrhagic or ischemic, therapeutic interventions are begun.

Some hospitals have a stroke team that evaluates all patients who arrive at the hospital within 2 hours of symptom onset. The stroke team will assess the patient within the first 15 minutes of arrival and have lab tests, ECG, and CT scans done with results back within 45 minutes after assessment. The HCP will make a decision regarding thrombolytic therapy within 1 hour of arrival.

Patients suffering from a stroke can develop increased intracranial pressure (ICP), which further adds to brain damage. Stroke patients are also at risk for repeated strokes. Careful serial neurologic assessments and vital signs are needed to promptly detect and report changes.

**Thrombolytic Therapy**

Some patients with ischemic stroke may be candidates for thrombolytic therapy. This is a “clot Buster” medication (alteplase [tissue plasminogen activator; tPA]) that can dissolve a clot and potentially completely reverse stroke symptoms. tPA works best when administered within 4.5 hours of symptom onset, so it is only an option if the patient arrives at the ED quickly after symptoms begin. Some patients awaken after a night’s sleep to discover they have had a stroke; their symptom onset is considered the time they went to bed, so they are not candidates for thrombolytic therapy.

Thrombolytic agents can lyse (disintegrate or break down) a thrombus by causing conversion of plasminogen to plasmin. Plasmin is the enzyme that causes thrombi to break down. Patients treated effectively with tPA may be able to leave the hospital within 1 or 2 days with no residual effects from the stroke. Thrombolytics are associated with a significant

**LEARNING TIP**

*Remember: Time lost is brain lost. This means the faster the patient with a stroke receives treatment, the more brain (and brain function) can be saved. Teaching your patients to recognize the signs and symptoms of a stroke and encouraging them to call 911 if needed could mean the difference between leading a normal life and total disability. Act FAST!*
risk of hemorrhage, so all risk of bleeding must be ruled out before these drugs will be considered. They are used very cautiously.

**Pharmacological Management**

Blood pressure control is vital for the stroke patient. Because of the lack of perfusion to certain areas of the brain, the body’s response is to increase the systolic blood pressure to force blood into the affected areas. If the patient will receive tPA, the blood pressure must be maintained below 185/110 mm Hg to reduce the risk of bleeding. This is often done through the use of a beta blocker (labetalol) or calcium channel blocker (nicardipine), because of their fast-acting effects and ability to be given IV. See Table 49.3 for medications commonly used for cerebrovascular disorders.

If tPA is not being given, the HCP may allow the blood pressure to remain high for a period of time to help salvage brain tissue, depending on the source of the stroke and the location of the clot. This “permissive hypertension” helps blood travel through collateral blood vessels in the brain to reach the affected area. Antihypertensive agents should be given if the systolic pressure exceeds 220 mm Hg or the diastolic pressure exceeds 120 mm Hg.

**Postemergent Care**

Once emergent treatment is completed, medical management focuses on controlling the cause of the TIA or stroke. The results of the diagnostic tests assist HCPs in determining the course of treatment. If the patient has residual physical deficits, the HCP will order physical, occupational, and speech therapy consultations to evaluate the patient’s functional status and make recommendations for further treatment.

The American Stroke Association recommends that patients who have a TIA or stroke receive an antiplatelet drug such as clopidogrel (Plavix), aspirin/dipyridamole (Aggrenox), or aspirin within 24 hours of symptom onset. Decreasing platelet aggregation lessens the likelihood of thrombus formation. The patient in atrial fibrillation may also receive an anticoagulant to prevent clot development.

Cholesterol-lowering medication, preferably a statin, will be ordered for patients who have a low-density lipoprotein (LDL) cholesterol level greater than 100 mg/dL. This will also help minimize the development of atherosclerotic plaques. Statins also may have a neuroprotective effect and may further decrease risk of a stroke.

Deep vein **thrombosis** (DVT) is of concern when caring for patients who have had a stroke. The decrease in movement, confinement to a hospital bed, and hypercoagulable state all increase risk of DVT. Not only can DVTs cause severe pain and complications in the affected leg, but the blood clot can dislodge and travel to the lungs and cause a pulmonary **embolism**, or to the brain and cause a repeat stroke. Prevention involves anticoagulant medication, or nondrug treatments such as sequential compression devices and elastic stockings.

 Patients are at risk for respiratory complications for several reasons, such as an increase in intracranial pressure. Patients with stroke are prone to aspiration because of a decreased level of consciousness and possibly impaired swallowing ability. Patients should be suctioned as needed to keep the airway clear. A patient who vomits should be turned to the side to reduce the risk of aspiration. Oral feedings should be started carefully and progressed slowly and only after the patient is alert and the ability to swallow safely has been determined by an appropriate swallowing evaluation.

Surgery

Patients with warning signs of stroke or patients who have been stabilized after a stroke may be candidates for surgery. In patients with significant carotid artery occlusion, a carotid endarterectomy may be performed. This involves a small incision in the neck and surgical removal of the occlusion from the artery.

Alternatively, a patient who is at high risk for complications with a carotid endarterectomy may have a carotid stent placed. This is placed during a carotid angiogram procedure. A catheter is advanced to the carotid artery, where a balloon is inflated to open the artery by pushing on the plaque. Then a stent (a tiny metal or polymer-based tube) is expanded inside the artery to keep it open and allow better blood flow to the brain.

CRITICAL THINKING

Mr. Jankowski

■ You are caring for Mr. Jankowski, a 56-year-old man who has been admitted to your orthopedic unit after knee surgery. As you listen to his lungs at the start of the shift, you notice that his lung sounds are diminished. You ask if he is a smoker and find that he has smoked for 40 years. You realize this will place Mr. Jankowski at risk for stroke.

1. What further data should you collect?
2. What preventive measures can you provide?
3. What resources can you provide to support smoking cessation?
4. What other interdisciplinary team members should you work with regarding your respiratory assessment?

Suggested answers are at the end of the chapter.

Prevention of Stroke

The incidence of stroke can be lessened by reducing risk factors (refer back to Box 49-1). Keeping hypertension, cholesterol level, weight, and diabetes controlled can go a long way toward preventing strokes. Smoking cessation is essential. Emboli may be prevented with warfarin in people at high risk from atrial fibrillation. Aspirin or other antiplatelet agents help prevent abnormal clotting.

It is important to educate all patients about new treatments for stroke and the potential for reversal of symptoms with the use of thrombolytic agents. Patients must be educated about risk factors for a stroke, warning signs, and the importance of immediate EMS transport if symptoms occur.

Long-Term Effects of Stroke

Impaired Motor Function and Sensation

Paresthesias and paralysis are common long-term effects of strokes that were not treated with a thrombolytic agent. The side of the body opposite the side of the cerebral infarct (the contralateral side) is affected because nerve fibers cross over as they pass from the brain to the spinal cord (Fig. 49.4). Bralitysis on one side of the body is called hemiplegia (Fig. 49.5). The affected limbs may be weak or totally paralyzed (flaccid).
arm or the leg may be weaker, depending on the artery affected. These patients are particularly prone to contractures, which cause permanent immobility of a muscle or joint from fibrosis of connective tissue. Adaptation or assistance with activities of daily living (ADLs) is required. Motor involvement also affects swallowing and control of urination and bowel function. Patients should be mobilized within 24 hours if possible to prevent complications of immobility. Physical and occupational therapy are provided to maximize functioning and to progress the patient toward a return to baseline functioning.

Sensation changes may prevent the patient from being aware of pressure, temperature, or injuries on the affected side. Patients must be taught to be aware of these changes and protect the involved limbs.

APHASIA. If a stroke affects the temporal lobe region, especially on the dominant side, the speech center will likely be affected. Aphasia may be expressive, receptive, or global, as described earlier. Patients may be able to say words but be unable to form coherent speech, such as the patient who picks up a fork but calls it a comb. If a patient does not understand what is said, avoid the temptation to speak louder to help the patient understand. Remember that it is not the patient's hearing that is affected. You need to be patient and understanding as the patient tries to communicate with you. Speech therapy can help the patient relearn to communicate. See the “Nursing Process for the Patient With a Cerebrovascular Disorder” section for interventions for the aphasic patient.

Emotional Lability

Emotional lability, or instability, is a common consequence of stroke. Patients may move rapidly from profound sadness to an almost euphoric state and back again. Laughing or crying may have no relationship to the patient’s situation at any given moment. Families can be upset by this behavior because they do not understand why a once happy person is now crying all the time or why the patient laughs inappropriately. For help in explaining that these responses probably do not reflect how the patient is feeling but rather are caused by the stroke damage.

Impaired Judgment

All patients who have had a stroke, especially those with right-sided lesions, present a high safety risk. Patients may have poor understanding of their own limitations and believe that they are capable of performing tasks they did before the stroke. These patients often have left-sided lesions are more likely to be hesitant even to try performing ADLs. These generalizations may be the opposite if the individual is predominantly left-handed. Precautions must be taken to protect the patient from injury.

If the frontal lobes are involved, learned social behaviors may be lost. The patient may undress in public, use profanity, or make inappropriate sexual advances. These behaviors are extremely difficult for significant others to cope with. Education and emotional support of significant others are essential. Allowing them to talk about their frustration and anger may facilitate coping. Distracting the patient from inappropriate behavior may help. The patient should never be reprimanded or punished because he or she no longer has the cognitive ability to control the behaviors.

Unilateral Neglect

The phenomenon of unilateral neglect is seen predominantly in patients who have right hemisphere infarcts. It has been estimated to affect up to 30% of all patients who have had a stroke. These patients do not acknowledge the left side of their environment and may not even be aware of their own body on the affected side. Safety is the primary consideration. Essential items such as the call light and telephone should be placed on the patient’s right side. Position the bed so the patient’s right side is to ward the door. Treatment should focus on providing stimuli to all senses on the patient’s affected side and teaching the patient to focus on the left side: This involves teaching the patient to purposefully check where the left limbs are positioned and to look for safety risks. The patient can learn to turn his or her head and scan the environment. Patients may also need reminders to accomplish simple tasks such as turning their plates during meals to recognize the food on the left side of the plate.

Other Long-Term Effects

The stroke patient may experience other complications after the acute phase of the stroke has passed. These include pneumonia, deep venous thrombosis, pulmonary embolism, pressure ulcers, malnutrition, and depression. For the homeward-bound patient, education for the patient and family regarding prevention and recognition of these complications will assist the patient in a successful recovery. If a patient needs to receive rehabilitation in a skilled nursing facility, prevention of these issues will be a part of the care plan at the facility. For more information, visit the National Stroke Association at www.stroke.org or the American Stroke Association at www.strokeassociation.org.

CEREBRAL ANEURYSM, SUBARACHNOID HEMORRHAGE, AND INTRACRANIAL HEMORRHAGE

A cerebral aneurysm is a weakness in the wall of a cerebral artery. It may be congenital, traumatic, or the result of disease. If the aneurysm ruptures, the result is often a subarachnoid hemorrhage. It is unknown what causes the formation of congenital aneurysms or what causes them to rupture. Unruptured aneurysms are typically asymptomatic. The exception is a very large aneurysm, which can cause symptoms similar to a brain tumor. Aneurysms often affect children and young, otherwise healthy adults.

Pathophysiology and Etiology

Aneurysms can occur in any of the cerebral arteries, although most occur in the circle of Willis. The most common site is at the bifurcation of an artery. It is theorized that increased turbulence at the bifurcation can cause an outpouching of a congenitally weak arterial wall.

Subarachnoid hemorrhage is the collection of blood beneath the arachnoid mater following aneurysm rupture. Rupture of
an arteriovenous malformation or head trauma may also result in subarachnoid hemorrhage (Fig. 49.6). The presence of blood outside the blood vessels is very irritating to brain tissue. It is believed that irritation from blood breakdown is the major cause of vasospasm, a common complication of subarachnoid hemorrhage.

It is unclear what causes an aneurysm to rupture. Some people develop a subarachnoid hemorrhage while performing Valsalva’s maneuver, engaging in sexual activity, or physically exerting themselves. For others, the aneurysm ruptures during a quiet, inactive period. If the aneurysm rupture is associated with a particular activity, the patient may be very frightened of engaging in that activity again. This may have a negative effect on the patient’s interpersonal relationships if the associated activity was sexual in nature. The patient’s partner may feel guilty or responsible for the hemorrhage. Education, emotional support, and confidentiality are essential to help both the patient and significant other.

**Signs and Symptoms**

Some patients experience a small hemorrhage before diagnosis of subarachnoid hemorrhage. This leakage of blood may cause a mild headache, vomiting, or disorientation. The symptoms may be attributed to a flulike syndrome. Patients may dismiss the symptoms and not seek medical care.

The most common presentation of rupture of an aneurysm is sudden onset of a severe headache. Typically, a patient will state, “I have never had a headache this bad in my life.” Patients may hold their heads and moan or cry in pain. Sensitivity to light is a common finding. This may make patients reluctant to cooperate with pupil examinations.

**LOC** varies based on the severity of the hemorrhage. Patients may be alert and coherent, may lose consciousness immediately, or may gradually become less responsive. The decreased LOC is caused by ICP and impairment of cerebral blood flow. Patients may experience generalized seizures.

Blood in the subarachnoid space causes meningeal irritation. The patient may exhibit nuchal rigidity. The most commonly affected cranial nerves are III and VI. This is manifested as an enlarged pupil or abnormal gaze. Motor dysfunction may involve one or both limbs on the side opposite the hemorrhage.

**Diagnostic Tests**

Because of the severe nature of the symptoms, patients with subarachnoid hemorrhage almost always come to the ED rather than seeking care from a primary HCP. A CT or an MRI scan is done to identify and locate a hemorrhage. Precise diagnosis of an aneurysm requires a cerebral angiogram. The contrast material fills the aneurysm if one exists. For a patient with a severe headache and facing a life-threatening illness, this test can be very frightening. If the patient’s neurologic status does not allow him or her to cooperate, sedation may be required before and during the examination.

**Therapeutic Measures**

Patients with subarachnoid hemorrhage are cared for in an intensive care unit (ICU) setting. They typically have an arterial line and a central venous pressure monitoring catheter. Blood pressure is carefully monitored because high pressures increase the risk of rerupture of the aneurysm and low pressures can be associated with ischemia. Values outside parameters identified by the HCP are reported. Typically, the systolic blood pressure is kept between 120 and 160 mm Hg. Vasoactive drugs may be required to maintain blood pressure within the prescribed parameters.

There is no cure for subarachnoid hemorrhage. Treatment consists of correcting the cause of the hemorrhage if possible. Preventing or managing complications and providing supportive care are important aspects of nursing care.

**Surgical Management**

Definitive treatment of the aneurysm involves performing a craniotomy and exposing the aneurysm. If the aneurysm has a neck (berry aneurysm), it is identified and clamped with a metal clip (Fig. 49.7). An aneurysm without a neck
may be wrapped with a sterile plastic or muslin wrap. This provides stability to the aneurysm walls, lessening the chance of rupture. In some situations, it is possible to clamp the artery on either side of the aneurysm, removing that portion of the vessel, and the aneurysm, from the circulation. After the removal, the ends are reconnected to maintain blood flow.

**Nonsurgical Management**

Nonsurgical intervention may be provided for aneurysms that are inoperable because of size, configuration, or the patient’s medical status. A foreign material such as a metallic or polymer-based coil may be introduced into the aneurysm. A thrombus develops around the foreign body and, if the treatment is successful, occludes the aneurysm. The goal is to fill the aneurysm enough to prevent blood flowing into it, without causing rupture.

**Complications**

**Rebleeding**

Recurrent rupture of a cerebral aneurysm carries significant morbidity and mortality rates. Patients are at risk for rebleeding until the aneurysm is surgically repaired. If the aneurysm is wrapped or embolized, there is a risk of rebleeding, but risk is much lower than if the aneurysm is left untreated.

**Hydrocephalus**

Blood in the ventricular system interferes with the circulation and reabsorption of cerebrospinal fluid (CSF), and hydrocephalus can develop. Early in the course of subarachnoid hemorrhage, an external ventricular drain may be used to treat hydrocephalus.

About 25% of patients with subarachnoid hemorrhage require placement of a ventriculoperitoneal shunt to treat hydrocephalus (Fig. 49.8). This surgical procedure involves placement of a catheter into a ventricle in the brain. The catheter is then connected to a valve, which regulates the rate of CSF drainage. Another catheter connects to the valve and is passed down to the peritoneal cavity. The CSF drains out of the peritoneal catheter and is absorbed into the peritoneal cavity.

**Vasospasm**

Vasospasm is responsible for most long-term complications of subarachnoid hemorrhage. Vasospasm causes a blood vessel’s diameter to narrow. Although it typically begins in the vessel giving rise to the aneurysm, vasospasm may spread to other vessels. This explains why the ischemia or infarct caused by vasospasm can be so widespread and devastating.

The long-term complications of subarachnoid hemorrhage are similar to those of stroke.

**Rehabilitation**

If the patient can tolerate intensive therapy, discharge from the hospital may be to a rehabilitation center. Rehabilitation and long-term care are similar whether the patient has had an aneurysm, intracerebral bleed, or an ischemic stroke.

---

**CRITICAL THINKING**

**Mrs. Washington**

- Mrs. Washington is a 68-year-old African American woman and retired office worker. She was admitted to your unit after a right-sided intracerebral hemorrhage. Her daughter states that Mrs. Washington has taken antihypertensive medication for the past 20 years. However, she states that her mother has been forgetful lately, and that there are five more pills in the medicine bottle than expected. On admission, Mrs. Washington is oriented only to person and has hemiparesis.

1. What may have precipitated Mrs. Washington’s stroke?
2. On which side do you expect Mrs. Washington’s extremities to be affected?
3. List two safety concerns and strategies to promote patient safety.
4. List at least two educational needs for Mrs. Washington and her daughter.
5. What health care providers are important in the interdisciplinary team caring for Mrs. Washington?

What is the role of nursing on this team?

*Suggested answers are at the end of the chapter.*
Nursing Process for the Patient With a Cerebrovascular Disorder

Data Collection

Observe the patient for signs and symptoms of decreased cerebral tissue perfusion: decreased level of consciousness, irritability or restlessness, syncope, blurred or dimmed vision, 

**diplopia** (double vision), change in visual fields, unequal pupils or a sluggish or absent pupillary reaction to light, paresthesias, motor weakness, paralysis, or seizures. Reassess frequently and report any decline. Monitor vital signs and oxygen levels. Monitor laboratory tests: CBC, lipid profile, and INR/PT if the patient takes warfarin (Coumadin). Perform a routine respiratory assessment. Monitor lung sounds for adventitious sounds or a change in breath sounds. Assess pain level. Assess swallowing ability before offering oral intake. Promptly report any changes in vital signs, laboratory values, respiratory function, or neurologic status.

Nursing Diagnoses, Planning, and Implementation

See the “Nursing Care Plan for the Patient With Stroke” for nursing diagnoses during acute care. Possible postacute nursing diagnoses are listed next with outcomes and interventions.

---

**NURSING CARE PLAN for the Patient With Stroke**

**Nursing Diagnosis:** Ineffective Cerebral Tissue Perfusion related to interruption of blood supply

**Expected Outcomes:** The patient will experience improved cerebral tissue perfusion as evidenced by:

- Absence of or reduction in dizziness, syncope, visual disturbances
- Improved level of consciousness
- Pupils equal and reactive to light
- Improved motor and sensory function.

**Evaluation of Outcomes:** Are the patient’s symptoms of ineffective perfusion improving?

**Intervention** Monitor neurologic status at least every 30 minutes initially and then every 4 hours or as ordered. Report changes. **Rationale** A change in status could indicate decreased perfusion. **Evaluation** Is there a change in neurologic status since the previous documented assessment?

**Intervention** Assess vital signs every 30 minutes initially and then every 4 hours or as ordered. **Rationale** High or low blood pressure can lead to decreased tissue perfusion and recurrent stroke. Temperature above 99.6°F can worsen ischemic injury to brain tissue. **Evaluation** Are vital signs within normal limits? Are changes reported?

**Intervention** Monitor oxygen saturation and administer oxygen as ordered for SpO2 less than 92%. **Rationale** Hypoxemia can increase brain damage. **Evaluation** Is SpO2 92% or greater?

**Intervention** Monitor blood glucose as ordered and report value greater than 140 mg/dL. **Rationale** Elevated glucose is associated with worsening of infarct and hemorrhage. **Evaluation** Is glucose level greater than 140 mg/dL? Was HCP notified?

**Intervention** Keep head of bed elevated 20 to 30 degrees. Keep neck in neutral position. **Rationale** This facilitates venous return and reduces risk of cerebral edema. **Evaluation** Is head of bed elevated? Is neck in neutral position?

**Intervention** Monitor medication for therapeutic and nontherapeutic effects. Monitor coagulation studies if appropriate. **Rationale** Anticoagulant therapy must be closely monitored to make sure it is at a therapeutic level and not increasing risk for bleeding. **Evaluation** Are coagulation studies within normal or therapeutic ranges? Are signs of bleeding present?

---

*Continued*
NURSING CARE PLAN for the Patient With Stroke—cont’d

Nursing Diagnosis: Ineffective Airway Clearance related to stasis of secretions associated with decreased mobility and poor cough effort and airway obstruction resulting from tongue falling back in throat

Expected Outcome: The patient will maintain an open airway as evidenced by respirations quiet and unlabored, 12 to 20 per minute, \( \text{SpO}_2 \) greater than 92%.

Evaluation of Outcome: Are respirations quiet, 12 to 20 per minute, with \( \text{SpO}_2 \) greater than 92%?

Intervention Monitor lung sounds, cough, and respirations. Rationale Assessment provides the basis for intervention. Evaluation Are lung sounds clear? Is cough effective? Are respirations quiet and easy?

Intervention Position the patient to maintain an open airway. Rationale Side lying may keep tongue from obstructing airway. Evaluation Is patient positioned to keep airway clear?

Intervention Consult with RN or HCP about an oral airway if airway is not clear. Rationale An oral airway will keep tongue from obstructing airway if needed. Evaluation Is an airway indicated?

Intervention Encourage patient to deep breathe and cough if able. Rationale Coughing and deep breathing will help clear secretions from airway and prevent atelectasis. Evaluation Is patient able to deep breathe and cough? Is cough effective?

Intervention If cough is ineffective, suction as needed. Rationale Suctioning may be needed if patient is unable to swallow secretions or cough effectively. Evaluation Is suctioning indicated? Is airway clear after suctioning?

Nursing Diagnosis: Risk for Injury related to seizure, repeat stroke, or hemorrhage secondary to thrombolytic therapy

Expected Outcome: The patient will remain free from injury.

Evaluation of Outcome: Is patient free from injury? Are problems recognized and reported quickly?

Intervention Monitor neurologic status frequently and report changes promptly. Rationale Prompt recognition of a repeat stroke is essential. Evaluation Are neurologic checks within normal limits? Are changes reported promptly?

Intervention Monitor for signs of hemorrhage for 24 to 36 hours following thrombolytic therapy. Rationale Hemorrhage is the most common side effect of thrombolytic therapy. Evaluation Are signs of hemorrhage present? Are they reported promptly?

Intervention Administer anticonvulsant agent as ordered. Rationale Patient is at increased risk for seizures following a stroke. Evaluation Is patient seizure free?

Intervention Implement seizure precautions (see Chapter 48). Rationale Precautions help protect patient in event of a seizure. Evaluation Are precautions in place and patient protected? Is patient assisted with mobility?

Intervention Assist with transfers and ambulation. Rationale Patient is at risk for falls because of motor and sensory deficits and impaired judgment. Evaluation Is patient able to call for help when needed?
Impaired Physical Mobility related to decreased motor function

**EXPECTED OUTCOME:** The patient will maintain physical mobility as evidenced by maximum physical mobility within limitations of deficits. Patient will not experience complications related to immobility.

- Consult physical and occupational therapists to assess the patient’s abilities and make specific recommendations related to mobility.
- Discuss use of constraint therapy with physical and occupational therapists. Constraint therapy forces the use of the affected limbs by restraining the unaffected side.
- Maintain the patient in correct body alignment to prevent contractures and promote comfort.
- Support affected extremities with pillows to prevent dislocation injuries and promote comfort.
- Perform range-of-motion exercises as prescribed by the physical therapist to prevent contractures and atrophy.
- Follow physical/occupational therapy recommendations for being up in chair or ambulation. Prolonged bedrest is associated with complications and poor outcomes.
- If patient is unable to get out of bed, turn and reposition at appropriate level for height, and no signs of aspiration.
- If swallowing appears to be intact, have patient swallow a sip of water from a cup before offering other foods or fluids. Observe for coughing, choking, or noisy lung sounds. These are signs of difficulty swallowing.
- Request speech pathologist evaluation if indicated to diagnose specific swallowing problems and make recommendations.
- Implement measures to prevent aspiration. Aspiration can lead to pneumonia, which will greatly complicate the patient’s recovery.
- Stay with patient during meals.
- Ensure that patient is fully alert before feeding.
- Place the patient in high-Fowler’s position or chair for meals.
- Avoid use of straws.
- Use a thickening agent if swallowing study recommends.
- Place food on unaffected side of mouth.
- Teach the patient to swallow twice after each bite.
- Check the patient’s mouth for pocketing of food.
- Have suction equipment available.
- Notify primary care provider if patient is unable to take in adequate oral calories. A feeding tube may be needed if the patient cannot take in enough calories to maintain nutrition. Advance directives should be consulted before a feeding tube is placed.
- Assist with insertion and care of feeding tube if needed. If patient cannot swallow effectively, a feeding tube may be needed to maintain nutrition.
- See “Nutrition Notes” and Chapter 47 for additional interventions.

**REFERENCE**

Imbalanced Nutrition, Less Than Body Requirements, related to impaired swallowing and motor deficits

**EXPECTED OUTCOME:** The patient will maintain adequate nutrition without aspiration as evidenced by stable weight at appropriate level for height, and no signs of aspiration.

- Keep patient NPO until swallowing can be evaluated to prevent aspiration.
- Perform dysphagia screening. This quick assessment can identify problems before a complete evaluation can be done.
- Observe for facial weakness or inability to completely close mouth.
- Ask patient to stick out tongue and move it side to side.
- Observe for drooling.
- If swallowing appears to be intact, have patient swallow a sip of water from a cup before offering other foods or fluids. Observe for coughing, choking, or noisy lung sounds. These are signs of difficulty swallowing.
- Request speech pathologist evaluation if indicated to diagnose specific swallowing problems and make recommendations.
- Implement measures to prevent aspiration. Aspiration can lead to pneumonia, which will greatly complicate the patient’s recovery.
- Stay with patient during meals.
- Ensure that patient is fully alert before feeding.
- Place the patient in high-Fowler’s position or chair for meals.
- Avoid use of straws.
- Use a thickening agent if swallowing study recommends.
- Place food on unaffected side of mouth.
- Teach the patient to swallow twice after each bite.
- Check the patient’s mouth for pocketing of food.
- Have suction equipment available.
- Notify primary care provider if patient is unable to take in adequate oral calories. A feeding tube may be needed if the patient cannot take in enough calories to maintain nutrition. Advance directives should be consulted before a feeding tube is placed.
- Assist with insertion and care of feeding tube if needed. If patient cannot swallow effectively, a feeding tube may be needed to maintain nutrition.
- See “Nutrition Notes” and Chapter 47 for additional interventions.

Disturbed Sensory Perception related to CNS damage

**EXPECTED OUTCOME:** The patient will adapt to sensory-perceptual deficits as evidenced by avoidance of injury to affected areas.

- Assist occupational therapist to assess for visual and/or spatial deficits and decreased sensory perception: heat and cold, position of body parts, pressure. Identification of specific deficits is the first step in creating a plan of care.
- Teach patient to scan the environment to compensate for a visual deficit.
- Implement plans for skin integrity and mobility to protect patient from complications related to sensory deficits.
Risk for Impaired Skin Integrity, Irritation or Breakdown, related to immobility and incontinence

EXPECTED OUTCOME: The patient’s skin integrity will be maintained as evidenced by absence of redness or breakdown.

• Examine the skin often for redness or breakdown, especially around bony prominences, dependent areas, and perineum. Any signs of breakdown must be treated immediately to prevent further damage.
• Thoroughly cleanse and dry the perineal area after each episode of incontinence. Urine and feces can be very irritating to the skin.
• If incontinence is unavoidable, use a barrier cream such as zinc oxide to protect skin.
• Turn and position the patient at least every 2 hours, or more often if the patient experiences breakdown. Pressure impairs circulation and increases risk of breakdown.
• Use a lift sheet to move patient in bed to avoid damage from friction and shear.
• Consider the use of a pressure-reducing mattress if patient cannot be out of bed for long periods. This helps reduce pressure but does not eliminate the need to reposition the patient every 2 hours.
• If breakdown occurs, contact the HCP or wound care specialist to obtain treatment recommendations.

Incontinence related to loss of voluntary control of elimination

EXPECTED OUTCOME: Episodes of incontinence are avoided, or if unavoidable, they will be cleaned up quickly and skin complications avoided.

• Monitor for incontinence of bowel or bladder so patient can be cleaned promptly and skin protected.
• Determine usual pattern of urinary and bowel elimination. Keeping the patient on his or her regular prehospitalization pattern may help prevent incontinence.
• Provide assistance with toileting according to the patient’s usual schedule. The patient who is unable to get up unaided may wait too long for help or try to get up alone and be injured.
• Respond quickly to requests for assistance with toileting to avoid accidental incontinence.
Self-Care Deficit related to impaired motor function, spatial-perceptual alterations, and fear of injury

**EXPECTED OUTCOME:** Self-care will be accomplished as evidenced by patient’s ADL needs being met and patient becoming increasingly independent.

- Determine the patient’s ability to perform ADLs. Good baseline data will guide development of a care plan.
- Work with the patient to create a plan for meeting daily physical needs. The patient will be more likely to participate in a plan if he or she participated in creating it.
- Encourage the highest level of independence possible; facilitate patient’s ability to do ADLs. Providing too much assistance can promote dependence and further loss of mobility.
  - Place objects within reach and within visual field.
  - Place food/fluids within patient’s visual field.
  - Encourage use of assistive devices.
  - Assist patient with learning to use nondominant side of body. If dominant side is affected, the patient may have to use the nondominant side.
  - Provide positive feedback to help reduce discouragement with slow progress.
  - Provide education for family members and significant others regarding patient’s deficits and recovery plan. The family can assist the patient with mobility if they understand what needs to be done.

Impaired Verbal Communication, Dysarthria, related to loss of motor function of the muscles of speech articulation, or aphasia or dysphasia related to ischemia of the dominant hemisphere

**EXPECTED OUTCOME:** Communication will be effective as evidenced by the patient communicating needs and desires effectively and by avoidance of frustration.

- Listen for difficulties in verbal communication (difficulty speaking, articulating or incorrect ordering of words, inability to find or name words and objects). Good baseline data will guide planning of care.
- Consult a speech pathologist for assistance in determining types of aphasia or dysphasia and need for follow-up treatment. A speech pathologist is specially trained to diagnose and treat communication problems and can work with nursing staff to develop a plan of care.
- Implement measures to facilitate communication. These measures help ensure the patient has his or her immediate needs met while learning to adapt to communication impairment.
  - Answer call light in person rather than over an intercom.
  - Assess needs frequently.
  - Listen carefully; avoid interrupting patient and allow ample time for communication.
  - When patient is tired, ask questions that require short answers.
  - Provide appropriate aids to communication (picture board, magic slate, pencil and paper). See Figure 49.9.
  - Provide education to family members and significant others regarding communication problems and interventions so they can communicate with patient and participate in care.

- If the patient is unable to communicate, do not assume that he or she cannot hear and understand. Make every effort to speak to the patient and to keep conversation appropriate when it is within the patient’s range of hearing. The patient may understand exactly what is being said, even if he or she is unable to respond.
- Contact HCP if impairment increases. This may be a sign of stroke extension.

Acute or Chronic Confusion related to cerebral ischemia

**EXPECTED OUTCOME:** The patient’s thought processes will be as clear as possible within limitations of brain damage as evidenced by responses appropriate to situation; the patient’s safety will be maintained and patient will feel calm and safe.

- Observe patient for thought process impairment such as shortened attention span, impaired memory, confusion, slowed or quick and impulsive responses, and aggressive and/or inappropriate responses. Disturbed thinking can be manifested in a variety of ways. See Chapter 48 for interventions for patients with disturbed thought processes.

Risk for Falls related to changes in mobility, sensation, or confusion

**EXPECTED OUTCOME:** The patient will remain safe and free from falls.

- Perform a fall risk assessment according to agency policy to identify patients at risk.
- Instruct the patient and family to call for help before the patient gets up so staff can assist.
- Keep call light and other essential items within patient’s reach to prevent falls while trying to access needed items.
- Provide frequent toileting. Patients often fall while getting up to use the toilet.
- Avoid restraints if at all possible. Restraints are associated with injuries.

Deficient Knowledge related to diagnosis and treatment

**EXPECTED OUTCOME:** The patient and family will have the necessary knowledge to make decisions and assist with care.

- Explain what has happened to the patient. Explain tests, procedures, and care activities. The patient and significant others are likely to be very frightened about what is happening. Providing correct information about what a stroke is, tests and procedures, and rationale for care activities helps reduce anxiety.
- Present information in small amounts and as simply as possible. The patient may have difficulty managing large amounts of information while acutely ill or if confusion is present.
- Orient the patient and family to the ICU or other setting and the constant monitoring provided. This can help reduce anxiety and reassure the patient and significant others that the patient is receiving competent care.
- If the patient is to be discharged to home, make sure information is provided related to medications, treatments, and follow-up care. The patient and family need to know how to provide appropriate care at home.
• Evaluate the need for home nursing, physical therapy, and occupational therapy, and request appropriate referrals. The patient will likely need continued therapy after discharge to regain as much function as possible.

**Risk for Caregiver Role Strain related to changes in roles, responsibilities, finances, and intimacy**

**Expected Outcome:** The caregiver will be comfortable with role as evidenced by statement that she or he understands how to care for the patient and has the needed resources to do so. The caregiver will maintain her or his own health.

• Work with caregiver to identify how the patient’s functional level will affect their lives. **Assumption of roles or responsibilities previously fulfilled by the patient may be very stressful to significant others. If the caregiver can anticipate the impact, he or she can plan ahead regarding how to make sure needs are met.**

• Encourage patient and caregiver to identify support systems and make use of community resources.

• Provide a list of resources. **If support is in place before discharge, they are more likely to use it after the patient goes home.**

• Consult social worker or case manager. **These individuals have access to many resources and can help the patient and caregiver identify appropriate sources of assistance, including a caregiver support group.**

• Provide support if transfer to a skilled nursing facility is needed. **This can be a very difficult decision for a patient and caregiver.**

**Evaluation**

If interventions have been effective, the patient will not experience increased deficits due to decreased perfusion of brain cells. The patient will recover as much physical ability as possible and adjust to remaining deficits to meet self-care needs. Basic needs, including safety, elimination, nutrition, and skin integrity, will be met by the patient or caregiver. The patient will be able to communicate effectively and have needs and desires understood. Caregivers will identify support systems available to help (Table 49.4).

- Work with a physical therapist, occupational therapist, and speech therapist to assist the patient with rehabilitation.
- Provide assistive devices to aid the patient to function independently.
- Keep home environment clutter-free to prevent falls.
- Offer frequent praise for all achievements.
- Keep regularly used items close by. If the patient is using a walker, have him or her tie a small bag to the top to store these items.
- If the patient does not have a portable phone, encourage the purchase of one. Instruct the patient to keep it near at all times in case of an emergency.
- If necessary, assist the patient with obtaining a medical alert device. If the patient falls, he or she can access an emergency medical service by pushing a button.
- Assist with obtaining homemakers or respite care for caregivers if necessary.
- Patients on a pureed diet can make their own food at home using a food processor. Baby food can also be purchased to meet swallowing guidelines.
- Patients with one-sided paralysis following a stroke can be taught to wear clothes that are easy to get on and off. Examples include pants with elastic waists, shoes with Velcro closures or slip-on shoes, and pullover shirts without buttons.
- If the patient has difficulty speaking (dysarthria), try using magnetic alphabet letters. Ask questions that require a yes or no answer. The patient can respond with the letter Y or N. You can also help the patient and caregiver develop a communication board of frequently used words and objects.
- Keep bedside commode lids up with patches of Velcro attached to the seat and the frame.

INR/PT = international normalized ratio/prothrombin time; PTT = partial thromboplastin time; SpO₂ = peripheral oxygen saturation.
CRITICAL THINKING

■ Mr. Jankowski
1. Ask Mr. Jankowski about other risk factors for stroke, such as his dietary and alcohol habits. Check his chart for history of diabetes, hypertension, or heart disease. Check his weight and cholesterol levels if drawn. Educate him about risk factors for stroke and how they can be modified. Use the Stroke Risk Scorecard and teach him the FAST acronym (see Fig. 49.2). As a nurse, you will be in a position to recognize risks and help patients modify risk factors for many problems before they occur.
2. Discuss use of an anticoagulant agent or sequential compression device with the RN or HCP.
3. Provide written or audiovisual information on stroke prevention and smoking cessation. Ask the HCP about use of a nicotine patch or other medication for smoking cessation, if Mr. Jankowski is willing.
4. Involve a dietitian for dietary counseling if indicated. Consult the smoking cessation coordinator at your agency if one is on staff.

■ Mrs. Washington
1. Uncontrolled hypertension, in the presence of a preexisting aneurysm, might have precipitated Mrs. Washington’s stroke.
2. Her left extremities will be affected.
3. Mrs. Washington is disoriented. Her room should be as close to the nurse’s station as possible. Reorient her to her surroundings and condition frequently. Keep side rails up when Mrs. Washington is alone.
   Mrs. Washington also has hemiparesis. Obtain a commode because Mrs. Washington will probably not be able to walk to the bathroom. Place the call light and telephone on her right side. Assist Mrs. Washington with positioning to prevent injury to her affected limbs.
4. If Mrs. Washington will be going back to her home, you should teach her and her daughter about the relationship of uncontrolled hypertension to intracranial hemorrhage; options for inpatient, outpatient, and in-home therapy; and memory strategies to prevent missed medication doses (e.g., weekly pill box, keeping medications with breakfast food, or an alarm clock or watch).
5. The HCP directs the medical care, but often it is the nurse (typically an RN) who oversees the multidisciplinary team and ensures that everything is being done as ordered. Other important team members include the case manager or discharge planner, dietitian, physical, occupational, and speech therapists, and pastoral care if the patient desires.

REVIEW QUESTIONS

1. Which of the following are modifiable risk factors that should be taught to patients at risk for stroke? Select all that apply.
   1. Heredity
   2. Age
   3. Diabetes
   4. Race
   5. High cholesterol
   6. Obesity

2. What interventions can help prevent aspiration in a poststroke patient with dysphagia? Select all that apply.
   1. Ensure that patient is fully alert before feeding.
   2. Place the patient in high-Fowler’s position or chair for meals.
   3. Use straws for thin liquids.
   4. Use a thickening agent.
   5. Place food on affected side of mouth.

3. How soon after symptom onset must a person who has had a stroke receive thrombolytic treatment?
   1. 30 minutes
   2. 1 hour
   3. 2 hours
   4. 4.5 hours

4. How should the nurse communicate with the patient experiencing receptive aphasia?
   1. Be patient as the patient tries to speak
   2. Listen carefully, while making eye contact
   3. Speak loudly toward the patient’s good side
   4. Use gestures, standing where the patient can see
5. A nurse is caring for a patient who is recovering from an ischemic stroke. Upon entering the room to pick up the supper tray, the nurse notes that the patient has only eaten food on the left side of the tray. What should the nurse do?
   1. Turn the plate 180 degrees and observe the patient’s response.
   2. Remove the tray and do not comment.
   3. Encourage the patient to eat the rest of the meal.
   4. Assist the patient by providing finger foods and feeding the patient items that require a utensil.

6. A nurse is doing an afternoon assessment on a patient transferred to a medical unit from intensive care following a subarachnoid hemorrhage. The patient was alert and oriented during the morning assessment but reported being very tired. Now the patient is difficult to arouse. What action should the nurse take?
   1. Let the patient sleep; transferring from the ICU can be very strenuous.
   2. Reassess the patient in an hour. If the sleepiness continues, notify the RN.
   3. Call the RN immediately.
   4. Call a code.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Identify disorders that are caused by disruption of the peripheral nervous system.
2. Explain the pathophysiology, major signs and symptoms, and complications of selected peripheral nervous system disorders.
3. Identify therapeutic measures used for selected peripheral nervous system disorders.
4. List common nursing diagnoses associated with peripheral nervous system disorders.
5. Plan prioritized nursing interventions for patients with peripheral nervous system disorders.
6. Evaluate the effectiveness of nursing care.
The peripheral nervous system (PNS) consists of all nervous system structures outside the central nervous system (CNS). A variety of disorders affect the PNS. Some of these disorders become chronic and cause degeneration of body systems. Some other disorders are more temporary. Two common types of PNS disorders are discussed in this chapter: neuromuscular disorders and cranial nerve disorders. Both types of disorders present a challenge to the nurse caring for the patient and family.

**NEUROMUSCULAR DISORDERS**

This group of neurologic conditions is chronic and degenerative in nature. Neuromuscular disorders involve a disruption of impulse transmission between neurons and the muscles they stimulate. This breakdown in transmission results in muscle weakness. If the muscles of the respiratory system are affected, deadly complications can develop, including pneumonia and respiratory failure. Common neuromuscular disorders include multiple sclerosis, myasthenia gravis, amyotrophic lateral sclerosis, and Guillain-Barré syndrome.

**Multiple Sclerosis**

**Pathophysiology**

Multiple sclerosis (MS) is a chronic progressive degenerative disease that affects the myelin sheath of the neurons in the CNS. Myelin is responsible for the smooth transmission of nerve impulses. Muscles contract when nerve impulses stimulate the muscle tissue. In MS, the myelin sheath begins to break down (degenerate; Fig. 50.1) as a result of activation of the body’s immune system. The nerve becomes inflamed and edematous, which interrupts impulses to the muscles. As the disease progresses, sclerosis or scar tissue damages the nerve. Nerve impulses become completely blocked, causing permanent loss of muscle function in that area of the body.

**Etiology**

The cause of MS is not really understood. Damage to the myelin sheath is thought to be from an autoimmune process; however, the disease can be related to viral infections, heredity and other unknown factors. Some research indicates that there is an inherited tendency to develop MS, and the manifestations of the disease only appear in the presence of environmental triggers. The disease usually starts between ages 15 and 50. Women are 2 to 3 times more likely to develop MS than men and are more likely to have relapses (National MS Society, 2013). Smokers and those with vitamin D deficiency have a higher risk of MS. Caucasians have a higher incidence of MS than those of African descent (Multiple Sclerosis Association of America [MSAA], 2013). The course of the disease is unpredictable, and there are many variations in symptoms, depending on which nerves are affected. Some individuals have mild illness, while others suffer permanent disability or rapid decline and death.

**Signs and Symptoms**

The patient with MS presents with muscle weakness, tingling sensations, and numbness. Other common symptoms include visual disturbances, usually in one eye at a time. These disturbances may be accompanied by pain with eye movement. Symptoms may begin slowly over weeks to months or start suddenly and dramatically. MS affects many body systems.

![Myelin sheath breakdown in multiple sclerosis](image_url)
Many factors can trigger the onset of symptoms or aggravate the condition, including extreme heat and cold, fatigue, infection, and physical and emotional stress. Hormonal changes after pregnancy can also cause symptom onset or exacerbation.

Periods of exacerbation and remission lead patients with MS to be uncertain about when the disease will flare up and what body system will be affected. Intense fatigue is common; therefore, immobility can become a problem. Accidents and falls are common because of muscle weakness or numbness of the trunk and limbs. Some people with MS experience symptoms such as muscle spasticity, bowel or bladder dysfunction, or paralysis. Difficulty with concentration or forgetfulness can also be problematic. Pneumonia can occur from immobility and from weakness of the diaphragm and intercostal muscles. Death, often resulting from respiratory infection, typically occurs 20 to 35 years after diagnosis.

**Diagnostic Tests**

Diagnosis is based on the patient’s history and signs and symptoms. Analysis of cerebrospinal fluid (CSF) may show an increase in oligoclonal immunoglobulin G (IgG). Magnetic resonance imaging (MRI) can be helpful in diagnosis because sclerotic plaques can be detected. A new blood test, gMS DX, is now available to help identify people likely to have identifying antibodies associated with MS. Evoked potential tests may be done to determine slow transmission of impulses.

**Therapeutic Measures**

MS has no cure. Many people with MS do well with no medication at all, although early treatment can delay progression of the disease. Interferon therapy with beta-interferons such as Betaseron or Avonex can reduce exacerbations and delay disability. Steroids such as adrenocorticotropin hormone (ACTH) and prednisone are given to decrease inflammation and edema of the neurons, which can relieve some symptoms. Immunosuppressants such as azathioprine (Imuran) and cyclophosphamide (Cytoxan) may be given to suppress the immune system. In 2012, oral teriflunomide (Aubagio) was added to the Food and Drug Administration–approved medications, and in 2013, dimethyl fumarate (Tecfidera) was added (MSAA, 2013). Clinical trials have shown that these medications can reduce the number and severity of relapses, reduce the number of new lesions shown on MRI, and for some, delay disease progression and disability. Each of these medications has serious side effects.

Anticonvulsants such as carbamazepine (Tegretol) or duloxetine (Cymbalta) help relieve neuropathic pain. Valium (Diazepam), baclofen (Lioresal), tizanidine (Zanaflex), and physical therapy assist in controlling muscle spasms. Bladder problems are treated with parasympathetic agents such as bethanechol (Urecholine) and oxybutynin (Ditropan). Fatigue can be treated with antidepressants or an antitiam agent such as amantadine (Symmetrel). Table 50.1 reviews additional medications used to treat PNS disorders.

For those who suffer sudden severe attacks or who do not respond to high doses of steroids, plasma exchange or plasmapheresis may be used to remove from the blood antibodies that are attacking the myelin (Box 50-2). New research is focusing on treatments to regenerate myelin.

Rehabilitation after an acute episode includes physical, speech, and occupational therapies. Rehabilitation therapy helps the patient and family adapt the home environment to the patient’s special needs. Assistive devices such as braces, canes, wheelchairs, and splints allow the patient increased mobility and independence. Patients who develop speech difficulties benefit from speech therapy. Exercise also can be beneficial (see “Evidence-Based Practice”).
Nursing Care

See the “Nursing Care Plan for the Patient With a Progressive Neuromuscular Disorder.”

In addition to reviewing routine care, instruct the patient to avoid factors that can exacerbate symptoms. This includes avoiding stressful situations as much as possible. Rest, exercise, and a balanced diet are important self-care steps to control symptoms. In addition, voiding extreme temperature changes, especially heat, and avoiding infection and illness are important. Any infection, especially respiratory, should be reported immediately to the health care provider (HCP). Two excellent sources of information on MS are the National Multiple Sclerosis Society at www.nationalmssociety.org and the Multiple Sclerosis Foundation at www.msfocus.org.

TABLE 50.1 MEDICATIONS USED TO TREAT PERIPHERAL NERVOUS SYSTEM DISORDERS

### Box 50-2  Plasmapheresis

Plasmapheresis, also known as plasma exchange therapy, is a procedure that removes the plasma component from whole blood and replaces it with fresh plasma. The goal is to remove antibodies through plasma exchange, suppressing the immune response and inflammation.

**Preprocedure Nursing Care**
- Teach patient about the procedure and what to expect, including what the machine looks like (similar to but smaller than a dialysis machine), the need for arterial and venous access sites, and the length of the procedure (2 to 5 hours).
- The HCP may order medications held until after the procedure. Some patients may require premedication, especially if they have experienced complications in the past.
- Assess baseline vital signs and weight.
- Assess complete blood cell count (CBC), platelet count, and clotting studies.
- Check blood type and crossmatch for replacement blood products.
- Observe the patient for signs of hypovolemia, such as dizziness and hypotension.
- Apply pressure dressings to the access sites.
- Monitor the patient for infection and bruits at the access site.
- Monitor electrolytes and signs of electrolyte loss. Report imbalances, and administer replacement electrolytes as ordered.
- Compare preprocedure and postprocedure laboratory data, such as CBC, platelet count, and clotting times.

### NURSING CARE PLAN  for the Patient With a Progressive Neuromuscular Disorder

**Nursing Diagnosis:** Ineffective Airway Clearance related to respiratory muscle weakness, with impaired cough and gag reflexes

**Expected Outcomes:** The patient will maintain a patent airway as evidenced by clear lung sounds and freedom from signs and symptoms of respiratory distress.

**Evaluation of Outcomes:** Is patient’s airway patent and are lung sounds clear? Is patient free of signs and symptoms of respiratory distress?
Chapter 50  Nursing Care of Patients With Peripheral Nervous System Disorders

NURSING CARE PLAN  for the Patient With a Progressive Neuromuscular Disorder—cont’d

**Intervention**  Monitor respiratory rate and depth, breath sounds, oxygen saturation (SpO2), and arterial blood gases (as ordered). Report deterioration.  **Rationale**  Increasing respiratory distress indicates progressing muscle weakness that may require mechanical ventilation or end-of-life decisions.  **Evaluation**  Is patient’s respiratory rate status stable or is intervention indicated?

**Intervention**  Encourage patient to cough and deep breathe every 2 hours.  **Rationale**  Effective coughing helps keep airway clear.  **Evaluation**  Does patient have the strength to cough effectively?

**Intervention**  Observe patient for breathlessness while speaking.  **Rationale**  Inability to speak without breathlessness indicates declining respiratory function.  **Evaluation**  Is patient able to finish sentences without needing to take a breath?

**Intervention**  Elevate head of bed.  **Rationale**  Fowler’s position improves lung expansion, decreases work of breathing, improves cough efforts, and decreases risk for aspiration.  **Evaluation**  Does elevation of head of bed help relieve dyspnea and prevent aspiration?

**Intervention**  Evaluate cough, swallow, and gag reflexes frequently. Notify HCP if absent.  **Rationale**  Frequent evaluation of reflexes is needed to prevent aspiration, respiratory infections, and respiratory failure.  **Evaluation**  Is patient able to cough effectively? Is gag reflex intact?

**Intervention**  Suction secretions as needed, noting color and amount of secretions.  **Rationale**  Muscle weakness can result in inability to clear airway.  **Evaluation**  Does patient require suctioning to clear airway? What color are secretions?

**Nursing Diagnosis:**  *Impaired Physical Mobility* related to muscle weakness

**Expected Outcomes:**  The patient will maintain optimum mobility and activity level, identify measures to help maintain mobility, and perform exercises that help maintain current mobility.

**Evaluation of Outcomes:**  Is optimum activity level maintained? Can patient identify measures that will help maintain mobility? Does patient perform exercises that help maintain mobility?

**Intervention**  Determine preillness and current level of mobility.  **Rationale**  Assessment guides care planning.  **Evaluation**  Do assessment findings help determine goals and interventions?

**Intervention**  Identify factors that affect ability to be mobile and active.  **Rationale**  Some factors that interfere with mobility can be modified.  **Evaluation**  Are interfering factors modified effectively?

**Intervention**  Encourage patient to perform self-care to maximum ability.  **Rationale**  Promotes sense of control and independence for patient.  **Evaluation**  Does patient perform self-care activities? Is assistance required?

**Intervention**  Consult physical therapist or occupational therapist to provide assistive devices for walking (canes, braces, walker, wheelchair) and other activities.  **Rationale**  Assistive devices decrease fatigue and promote independence, comfort, and safety.  **Evaluation**  Does patient use assistive devices safely during activities? Do they help keep patient active?

**Intervention**  Reposition frequently when patient is immobile.  **Rationale**  Prevents skin breakdown and stasis of pulmonary secretions.  **Evaluation**  Is patient free from complications of immobility?

**Intervention**  Provide active/passive range-of-motion (ROM) exercises on a regular basis.  **Rationale**  Prevents contractures and disuse atrophy.  **Evaluation**  Does patient have any contractures or atrophy?

**Intervention**  Plan activities with a balance of frequent rest periods.  **Rationale**  Rest decreases fatigue.  **Evaluation**  Is fatigue controlled?
### NURSING CARE PLAN for the Patient With a Progressive Neuromuscular Disorder—cont’d

**Intervention** Administer medications as ordered. **Rationale** Medications can slow progress of disease and reduce symptoms that limit mobility. **Evaluation** Are symptoms controlled?

**Nursing Diagnosis:** Risk for Imbalanced Nutrition: Less Than Body Requirements related to weakness or lack of coordination of muscles for chewing and swallowing

**Expected Outcome:** The patient will maintain body weight within normal limits for height and frame.

**Evaluation of Outcome:** Is patient’s weight stable and within normal limits?

**Intervention** Evaluate cough, swallow, and gag reflexes frequently. Notify HCP if absent. **Rationale** If patient is unable to swallow, a feeding tube may be indicated, depending on patient’s wishes. **Evaluation** Does patient eat and drink without aspirating?

**Intervention** Offer soft foods that are easy to chew and swallow. **Rationale** Soft foods require less effort to chew and are less fatiguing. **Evaluation** Is patient able to chew and swallow without excessive fatigue?

**Intervention** Request speech therapist and dietitian consultations as indicated. **Rationale** Speech therapist can help evaluate swallowing and make recommendations. Dietitian can recommend appropriate foods. **Evaluation** Are consults indicated? Are recommendations implemented?

**Intervention** Institute swallowing precautions as needed. **Rationale** Swallowing precautions help prevent aspiration and allow patient to maintain oral intake as long as possible. **Evaluation** Do precautions prevent aspiration?

**Nursing Diagnosis:** Impaired Verbal Communication related to impaired respiratory and muscle function

**Expected Outcome:** The patient will be able to communicate needs.

**Evaluation of Outcome:** Does patient indicate that needs are met with a minimum of frustration?

**Intervention** Assess ability to speak and communicate. **Rationale** Assessment is essential to planning appropriate communication interventions. **Evaluation** Can patient speak or communicate needs?

**Intervention** Request referral to speech therapist for assistance if indicated. **Rationale** Speech therapist can recommend appropriate alternative communication techniques. **Evaluation** Is speech therapy referral indicated? Is referral completed?

**Intervention** Assess for nonverbal signs of pain or distress, such as restlessness, agitation, grimacing. **Rationale** Patient may not be able to tell you if he or she is in pain or distress. **Evaluation** Are signs of pain or distress present? Are they attended to?

**Intervention** Use picture board or paper and pencil. Ask questions that require a yes or no answer. **Rationale** These do not require the patient to speak to communicate. **Evaluation** Do alternative methods help patient communicate needs?

**Intervention** Use unhurried, calm, and caring approach while providing care. **Rationale** This will help decrease anxiety and provide emotional support to patient and family. **Evaluation** Do patient and family appear anxious? Does calm approach help?

**Intervention** Explain all procedures. **Rationale** Patient can still hear and needs to know what is happening. **Evaluation** Does patient indicate understanding?
Myasthenia Gravis

Pathophysiology

Myasthenia gravis (MG) means “grave muscle weakness,” or weakness of the voluntary or skeletal muscles of the body. MG is a noncommunicable (chronic) disease of the neuromuscular junction (Fig. 50.2). Normally, at the neuromuscular junction, the neuron releases the chemical neurotransmitter acetylcholine (ACh), which crosses the synaptic cleft. Receptors on the muscle tissue take up ACh and contraction of the muscle results. In MG, the body’s immune system is activated, producing antibodies that attack and destroy ACh receptors at the neuromuscular junction. Therefore, ACh cannot stimulate muscle contraction because the number of ACh receptors has been reduced, resulting in loss of voluntary muscle strength.

Etiology

MG is a chronic autoimmune process. No specific cause has been found for MG. However, current thought is that a virus or bacteria may initiate the autoimmune process. Genetic susceptibility may also play a role. Disorders of the thymus gland are often associated with MG. Thymomas or tumors on the thymus gland can account for the malfunction of the immune system that initiates the autoimmune process. All ethnic groups and both genders can develop this disease. Peak age of onset in women is ages 20 to 30. Men are affected more often after age 60. MG occurs slightly more often in women than men.

Signs and Symptoms

MG results in progressive extreme muscle weakness. The classic sign of MG is increased muscle weakness during activity and improvement in muscle strength after rest. Muscles are strongest in the morning, when the person is rested. Activities affected by MG include eye and eyelid movements, chewing, swallowing, speaking, and breathing, as well as skeletal muscle function. Patients often present with drooping of the eyelids (ptosis). Facial expressions become masklike. After long conversations, the patient’s voice can fade. Falls occur because of weakness of the arm and leg muscles. Patients with MG experience periods of exacerbation and remission of symptoms, similar to patients with MS. Exacerbations can be caused by emotional or physical stress such as menses, illness, trauma, extremes in temperature, pregnancy, electrolyte imbalance, surgery, and drugs that block action at the neuromuscular junction.

Complications

Major complications associated with MG result from weakness of muscles that assist with swallowing and breathing. Aspiration, respiratory infections, and respiratory failure are the leading causes of death. Sudden onset of muscle weakness in patients with MG resulting from not enough medication is called a myasthenic crisis. Overmedication with anticholinesterase (anti-ACh) drugs causes a cholinergic crisis (Table 50.2). Both crises require immediate medical attention.

LEARNING TIP

Symptoms of cholinergic crisis can be remembered with the acronym SLUDGE: salivation, lacrimation, urination, diarrhea, gastrointestinal (GI) cramping, and emesis. A severe crisis has been described as “liquid pouring out of every body orifice.”

Diagnostic Tests

Diagnosis of MG is based on history of symptoms and physical examination of the patient. A simple test involves the patient looking upward for 2 to 3 minutes. Increased droop of the eyelids (ptosis) occurs if MG is present. After a brief rest, the eyelids can be opened without difficulty. Another test is done by injecting edrophonium (Tensilon, an anticholinesterase...
drug) intravenously (IV). If muscle strength improves dramatically (e.g., the patient can suddenly open the eyes wide), MG is diagnosed. However, improvement is only temporary. An increased number of anti-ACh receptor antibodies in the blood are present in 90% of patients with MG. Electromyography (EMG) may be done to rule out other conditions. Pulmonary function tests may be done to predict potential myasthenic crisis leading to respiratory failure.

**Therapeutic Measures**

No cure is currently available for MG. Treatment is aimed at controlling symptoms. Removal of the thymus gland (thymectomy) can decrease production of ACh receptor antibodies and decrease symptoms in most patients. Medications used to treat MG include the anticholinesterase drugs neostigmine (Prostigmin) and pyridostigmine (Mestinon). These drugs improve MG symptoms by destroying the acetylcholinesterase that breaks down ACh. Remember that ACh causes muscles to contract. If ACh is allowed more time to attach to muscle tissue receptors, the muscle contracts and strength is increased. Steroids such as prednisone and immunosuppressants are used to suppress the body’s immune response. Plasmapheresis can be used to remove antibodies from the patient’s blood (Box 50-3). Use of immune globulin is being researched.

**Box 50-3 Medications That Can Exacerbate Symptoms of Myasthenia Gravis**

- Antibiotics (some)
- Alpha interferon
- Anticholinergic agents
- Beta blockers
- Botulinum toxin
- Calcium channel blockers
- Chloroquine
- Lithium
- Magnesium
- Neuromuscular blocking agents (such as those used during surgery)
- Penicillamine
- Prednisone
- Procainamide
- Quinidine

**Nursing Process for the Patient With Myasthenia Gravis**

**DATA COLLECTION.** Determine the patient’s baseline muscle strength. Ask how much activity is tolerated before fatigue and muscle weakness occur. Identify the patient’s support systems and determine whether the patient’s needs are being met. Assess the knowledge base of the patient and family. Check respiratory function and swallowing ability.

**NURSING Diagnoses, Planning, and Implementation.**

**Activity Intolerance related to muscle weakness**

**EXPECTED OUTCOME:** The patient will improve activity tolerance as evidenced by ability to carry out necessary activities.

- Schedule anticholinesterase drugs so that peak action occurs at times when increased muscle strength is needed so the patient has strength for activities such as meals and physical therapy.
- Teach the patient to schedule activities such as grocery shopping or errands at times when medication is at peak action, so that muscle strength is adequate for the activity.
- Be aware of symptoms and treatment of myasthenic and cholinergic crises, so quick intervention can be carried out to prevent worsening symptoms.
- Teach the patient and significant others signs and symptoms of crisis conditions because both crises constitute medical emergencies and require immediate medical attention (see Table 50.2).
- Teach methods to conserve energy, such as sitting down to do grooming and housekeeping activities whenever possible. This helps the patient conserve energy to manage ADLs.
- Teach the patient to rest between activities to allow time for muscle strength to be restored.
Chapter 50  Nursing Care of Patients With Peripheral Nervous System Disorders

• Teach the importance of avoiding people with infections and exposure to cold to minimize risk for respiratory infections, which can exacerbate symptoms and increase risk for ineffective airway clearance.
• Instruct the patient to eat nutritious, well-balanced meals to maintain strength and resistance to infections, which can exacerbate symptoms.
• Teach the patient to only use medications that are prescribed by the HCP. If multiple providers are used, all medications should be checked with the provider who is treating the MG. Many medications can exacerbate muscle weakness (Box 50-3).
• Provide information about support groups that can provide encouragement and assistance to patients and their families.

EVALUATION. If the plan of care has been effective, the patient’s activity and self-care needs will be met, either by the patient or by other support individuals.

Also see the “Nursing Care Plan for the Patient With a Progressive Neuromuscular Disorder.” More information can be found at the Myasthenia Gravis Foundation of America website at www.myasthenia.org.

CRITICAL THINKING

Jamie

Jamie is referred to a neurologist because of muscle weakness.

1. What history can help differentiate between MS and MG?
2. What physical examination can be done to differentiate between MS and MG?
3. The neurologist prepares to do a Tensilon test and asks you to prepare 2 mg of Tensilon for IV injection. It is supplied as 10 mg per milliliter. How much should you draw up?
4. In preparing for a case management meeting for a patient with a neuromuscular disease, which other HCPs should be invited?

Suggested answers are at the end of the chapter.

Amyotrophic Lateral Sclerosis

Pathophysiology and Etiology

Amyotrophic lateral sclerosis (ALS, also called Lou Gehrig’s disease) is a progressive, degenerative condition that affects motor neurons responsible for the control of voluntary muscles. In the brain and spinal cord, upper and lower motor neurons begin to degenerate and form scar tissue or die, blocking transmission of nerve impulses. Without stimulation, muscles atrophy, and muscle strength and coordination decrease. As the disease progresses, more muscle groups, including muscles controlling breathing and swallowing, become involved. The heart and GI tract are controlled involuntarily, and so are not affected by ALS. The ability to think and reason also is not affected.

ALS can occur at any age but usually does not appear until adulthood. The cause of ALS is not known, but it is believed to have a genetic component.

Signs and Symptoms

Symptoms are vague early in the course of ALS. Primary symptoms include progressive muscle weakness and decreased coordination. This can begin in the arms, legs, or muscles of speech and swallowing. Atrophy of muscles and fasciculations (twitching) also occur. Muscle spasms can cause pain. Difficulty with chewing and swallowing place the patient at a risk for choking and aspiration as the disease progresses. Inappropriate emotional outbursts of laughing and crying can occur. Speech becomes increasingly difficult. Bladder and bowel functions remain intact, yet problems such as constipation, urinary urgency, hesitancy, or frequency can occur.

Late in the disease, communication becomes limited to moving and blinking the eyes in response to questions. Pulmonary function becomes severely compromised to the point of requiring mechanical ventilator assistance if the patient chooses. Other complications can include extreme malnutrition, falls, pulmonary emboli, and congestive heart failure. ALS eventually leads to death from respiratory complications such as atelectasis, respiratory failure, and pneumonia.

Diagnostic Tests

Diagnosis is made based on clinical symptoms. Additional tests such as CSF analysis, electroencephalogram (EEG), nerve biopsy, nerve conduction velocity (NCV), or EMG may be done to rule out other conditions. Blood enzymes can be increased as a result of muscle atrophy.

Therapeutic Measures

There is no cure for ALS, and treatments are palliative in nature. Goals of treatment are aimed at improving function as long as possible and emotionally supporting the patient and family through the illness. Baclofen (Lioresal) and diazepam (Valium) may be given to relieve muscle spasticity. Quinine may be used for muscle cramps. Riluzole (Rilutek) slows the progression of the disease and can prolong life by 3 to 4 months. New treatments are constantly being researched.

Nonpharmacological measures such as physical therapy, massage, position changes, and diversional activities can help control pain. Tube feedings via a surgically placed gastrostomy tube help provide adequate nutrition. Prevention of infections, such as pneumonia and urinary tract infection (UTI), is vital. Meticulous skin care minimizes the incidence of pressure ulcers. Physical, occupational, and speech therapies allow the patient to maximize function and control for as long as possible. Therapy can also decrease the occurrence of complications such as aspiration, falls, and contractures.

• WORD BUILDING •

amyotrophic: a—without + myo—muscle + trophic—nourishment
atrophy: a—without + trophic—nourishment
Patients with speech problems may benefit from the use of augmentative alternative communication. A variety of such systems are available; most involve laptop computers that patients can use to type in words or symbols to generate speech. Medicare pays at least a portion of the cost for the equipment. Support groups and counseling provide emotional support for the patient and family.

Nursing Care

See the “Nursing Care Plan for the Patient With a Progressive Neuromuscular Disorder.”

PATIENT EDUCATION. Reinforce information given by the HCP to the patient and family about ALS and its prognosis. Support groups can provide emotional support as the patient and family deal with the likely reality of untimely death. Assistive devices and exercises help prevent complications. Teaching family members how to perform physical therapy and other health care activities allows the patient to spend as much time as possible at home. Teach the patient to avoid exposure to persons with infections because an infection can be deadly to a patient with a debilitating disease. Request a consultation with a palliative care specialist or other resource person at your institution to help the patient and family develop an advance directive.

Guillain-Barré Syndrome

Pathophysiology

Guillain-Barré syndrome (GBS) is a rare neuromuscular disease affecting only 1 in every 100,000 persons. Both men and women in the United States are affected equally. Onset is usually between 30 and 50 years of age. GBS is an inflammatory disorder characterized by abrupt onset of symmetrical paresis (weakness) that progresses to paralysis. The myelin sheath of the spinal and cranial nerves is destroyed by a diffuse inflammatory reaction. The peripheral nerves are infiltrated by lymphocytes, which leads to edema and inflammation. Segmental demyelination causes axonal atrophy, resulting in slowed or blocked nerve conduction. Typically, the demyelination begins in the most distal nerves and ascends in a symmetrical fashion. Remyelination, which is a much slower process, occurs in a descending pattern and is accompanied by a resolution of symptoms.

There are four recognized variants of GBS; however, only the most common type, ascending GBS, is addressed in this chapter. It is characterized by progressive weakness and numbness that begins in the legs and ascends up the body. The numbness tends to be mild, but the muscle weakness usually progresses to paralysis. The paralysis can ascend all the way to the cranial nerves or stop anywhere between the legs and head. Deep tendon reflexes are either depressed or absent. Respiratory function becomes compromised in approximately 50% of patients with ascending GBS.

Etiology

GBS is believed to be caused by an autoimmune response to some type of viral infection or to certain vaccines, although the exact cause is not known. Usually the viral illness affects the respiratory or GI system, and occurs within 2 weeks before onset of neurologic symptoms. The most common organism found to be associated with GBS is Campylobacter jejuni, a common cause of gastroenteritis.

Signs and Symptoms

GBS is divided into three stages.

STAGE 1, ONSET OF SYMPTOMS. The first stage starts with the onset of symptoms and lasts until the progression of symptoms stops. This stage can last from 24 hours to 3 weeks and is characterized by abrupt and rapid onset of muscle weakness and paralysis, with little or no muscle atrophy. Many patients give a history of a recent viral illness or vaccination, supporting the theory that the cause is autoimmune in nature. The degree of respiratory involvement correlates to the type of GBS and the level of paralysis. Patients with ascending GBS may gradually notice a reduced ability to take deep breaths or carry on conversations and may feel short of breath. These patients are terrified that they will not be able to breathe and may require intubation and artificial ventilation.

The autonomic nervous system is often affected by GBS. Patients can experience labile blood pressure, cardiac dysrhythmias, urine retention, or paralytic ileus. Patient reports of discomfort range from annoying numbness and cramping to severe pain. The discomfort is exacerbated by the patient’s inability to move voluntarily.

WORD BUILDING

demyelination: de—down or from + myelin—sheath surrounding neurons + ation—process

remyelination: re—repeat + myelin—sheath surrounding neurons + ation—process
STAGE 2, PLATEAU. The second stage is the plateau stage, when symptoms are most severe but progression has stopped. It can last from 2 to 14 days. Patients may become discouraged if no improvement is evident.

STAGE 3, RECOVERY. Axonal regeneration and remyelination occur during the third state, recovery. This stage lasts from 6 to 24 months and symptoms slowly improve. Most patients with GBS recover completely within a few months to a year. A few patients experience chronic disability.

Complications
Complications that can occur include respiratory failure, infection, and depression. Fatigue and paralysis of the respiratory muscles lead to insufficient respiratory effort. Some patients with impending respiratory failure attempt to convince the staff that they are not in distress and do not need to be intubated. It is important to discuss the possible need for intubation early in the patient’s illness. The decision to intubate in GBS is different from that with other PNS disorders because GBS patients are expected to recover. It is important to be vigilant in monitoring pulse oximetry, respiratory rate and depth, and dyspnea to predict the need for intervention and maintain the patient’s safety.

Patients with GBS are prone to pneumonia and UTIs. Maintaining infection control practices and maximizing the patient’s nutritional status help decrease the likelihood of infection. Immobility leads to such problems as skin breakdown, pulmonary embolus, deep vein thrombosis, and muscle atrophy. Patients with GBS have little time to adjust to their illness and deterioration, and often fear they will not recover function. Calm, supportive reassurance is important.

Diagnostic Tests
A lumbar puncture is performed to obtain CSF. The CSF analysis shows a normal cell count with an elevated protein level. Electromyographic and nerve conduction velocity tests are done to evaluate nerve function. Pulmonary function testing helps confirm impending respiratory problems.

Therapeutic Measures
During the initial stages, patients are partially or completely dependent for all needs. They are often frightened and anxious. Oxygen and mechanical ventilation may be required. Plasmapheresis may be used to remove the patient’s plasma and replace it with fresh plasma. This procedure is thought to lessen the body’s immune response. To be most effective, plasmapheresis should begin 7 to 14 days from the onset of symptoms. Immunoglobulin therapy may help reduce the severity of the disease. Steroid hormones, although used in the past, are not effective and may be harmful. Supportive interventions include anticoagulants to prevent deep vein thrombosis, and analgesics for pain.

During the plateau phase, patients can become discouraged because they are not getting any better. Emotional support is important during this phase. Axonal regeneration and remyelination occur during the recovery phase. Intensive rehabilitation helps the patient regain function during this phase.

Nursing Process for the Patient With Guillain-Barré Syndrome
See the “Nursing Care Plan for the Patient With a Progressive Neuromuscular Disorder.” In addition, be prepared to teach the patient and family about the disease and treatment.

DATA COLLECTION. Assess the patient’s vital signs, ABGs, and SpO₂ to monitor respiratory status. Assess gag, corneal, and swallowing reflexes to determine whether safety measures are needed to prevent aspiration or injury to the eyes. Assess the patient’s and family’s knowledge about the disease and treatment.

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.
Deficient Knowledge related to new diagnosis and treatment

EXPECTED OUTCOME: The patient and family will verbalize understanding of what to expect as disease progresses, how treatments will help, and how to participate in care.

- Explain all procedures to the patient and family. Patients and family members who understand the rationale for assessments or interventions are more likely to cooperate and assist.
- Educate the patient and family about the need for frequent respiratory assessments and possible need for temporary respiratory support. Patients may deny respiratory difficulty because of a fear of intubation and mechanical ventilation.
- Teach and encourage use of diversional activities such as visits from family and friends, listening to music or relaxation tapes, and watching television or videos. Recovery can be prolonged, and diversional activities can help alleviate boredom, loneliness, and depression.
- As the patient begins to regain function, assist in teaching patient and family how to participate in patient care and therapies. Encourage family members to attend therapy appointments. Participation in patient care activities and therapies can provide a sense of control over the situation and helps prepare the patient and family for discharge.
- Provide information about the disease, treatments, and recovery. Recovery can take months or years; most of that time will be spent at home.

EVALUATION. If interventions have been effective, the patient and family will demonstrate understanding of the disease process and participate in care appropriately. Table 50.3 summarizes and compares MS, MG, ALS, and GBS.

Postpolio Syndrome
Pathophysiology and Etiology
Postpolio syndrome is a condition that affects survivors of polio 20 to 40 years after they have recovered from infection caused by the poliovirus. Up to 40% of patients who previously had polio develop this syndrome. The severity of the syndrome depends on the degree of residual weakness and disability left from the initial illness.

Signs and Symptoms
Postpolio syndrome involves a further weakening of the muscles that were affected with the first involvement with

CSF = cerebrospinal fluid; EEG = electroencephalography; EMG = electromyography; MRI = magnetic resonance imaging; NCV = nerve conduction velocity; UTI = urinary tract infection.
the poliovirus. Symptoms range from fatigue to progressive muscle weakness and atrophy. Sleeping problems, joint pain, scoliosis, and respiratory compromise can occur. Some people suffer great debilitation; others have fewer problems.

**Diagnostic Tests**

Observation and history and excluding other problems are most important in diagnosis of this syndrome.

**Therapeutic Measures**

No interventions have been found to be effective at this time. Symptoms seem to be best controlled by rest and moderate exercise without pushing the limits of tolerance.

---

**CRANIAL NERVE DISORDERS**

Cranial nerves are the peripheral nerves of the brain. There are 12 pairs of cranial nerves. Areas that the cranial nerves innervate include the head, neck, and special sensory structures (see Chapter 48). Cranial nerve problems are classified as peripheral neuropathies. Disorders can affect the sensory, motor, or both branches of a single nerve. Causes of cranial nerve disorders include tumors, infections, inflammation, trauma, and unknown causes. Two common cranial nerve problems are trigeminal neuralgia (tic douloureux) and Bell’s palsy.

**Trigeminal Neuralgia**

**Pathophysiology and Etiology**

Trigeminal neuralgia (TN), sometimes called tic douloureux, involves the fifth cranial (trigeminal) nerve. This cranial nerve has three branches that include both sensory and motor functions. The branches innervate areas of the face, including the forehead, nose, cheek, gums, and jaw. TN affects only the sensory portion of the nerve. Irritation or chronic compression of the nerve is suspected to initiate symptoms. This condition is seen more often in women and usually begins around age 50 to 60.

**Signs and Symptoms**

Intense recurring episodes of pain, described as sudden, jabbing, burning, or knife-like, characterize this condition. Episodes of pain begin and end suddenly, lasting a few seconds to minutes. Attacks can occur in clusters up to hundreds of times daily. However, some patients have only a few attacks per year. Pain is felt in the skin on one side of the face. A slight touch, cold breeze, talking, or chewing can trigger attacks of pain. The areas of the face where pain is triggered are referred to as trigger zones. Areas affected include the lips, upper or lower gums, cheeks, forehead, or side of the nose (Fig. 50.3). Sleep provides a period of relief from the pain. Therefore, persons with trigeminal neuralgia may sleep most of the time to avoid painful attacks. They also may refrain from activities such as talking, face washing, teeth brushing, shaving, and eating to prevent pain. Frequent blinking and tearing of the eye on the affected side also occur.

**Diagnostic Tests**

History of symptoms and direct observation of an attack confirm diagnosis. Radiological studies, including computed tomography (CT) and MRI, may be used to rule out other causes of the pain.

**Therapeutic Measures**

Initial management includes the use of anticonvulsants such as phenytoin (Dilantin), gabapentin (Neurontin), or carbamazepine (Tegretol) to reduce transmission of painful nerve impulses. Baclofen or clonazepam may also be effective in controlling symptoms. If medications are not effective, a nerve block using a local anesthetic may be performed. This option offers 8 to 16 months of relief. If medications and nerve blocks do not provide relief, a rhizotomy can be done to destroy selected nerve fibers. A neurectomy may be done if no vessel is found to be compressing the nerve. Surgical options leave the patient with varying degrees of numbness. Complementary and alternative therapies such as acupuncture, electrical stimulation, vitamin and nutritional therapy may be used with varying success.

**PATIENT EDUCATION POSTPROCEDURE.** The patient will need to learn to protect anesthetized areas of the face after nerve block or ablation. If corneal sensation is lost, goggles and sunglasses should be used as needed to protect the affected eye. An eye patch may be needed at night to prevent injury during sleep. Artificial tears may also be needed to prevent corneal damage.

**Bell’s Palsy**

**Pathophysiology and Etiology**

In Bell’s palsy, the facial nerve (cranial nerve VII) becomes inflamed and edematous, causing interruption of nerve impulses. The cause is thought to be nerve trauma from a viral infection.
such as Epstein-Barr, herpes simplex, or herpes zoster. Loss of motor control typically occurs on one side of the face; bilateral facial palsy occurs in less than 1% of cases. Contracture of facial muscles can occur if recovery is slow. Men and women are affected equally. Bell’s palsy is more common in women in the third trimester of pregnancy, in people with immune disorders such as human immunodeficiency virus (HIV) infection, and in people with diabetes. It occurs in all ages (including children) and at all times of the year.

**Signs and Symptoms**

Onset of symptoms may be sudden or may progress over a 2- to 5-day period. The severity of the paralysis usually peaks within several days of onset of symptoms. Pain behind the ear may precede the onset of facial paralysis. Other vague initial symptoms are dry eye or tingling around the lips with progression to the more recognizable symptoms of Bell’s palsy. The patient may be unable to close the eyelid, wrinkle the forehead, smile, raise the eyebrow, or close the lips effectively. The mouth is pulled toward the unaffected side (Fig. 50.4). Drooling of saliva occurs, and the affected eye has constant tearing. Sense of taste is lost over the anterior two-thirds of the tongue. Speech difficulties occur. Fifty percent of patients will have complete recovery in a short period of time. Thirty-five percent will experience full recovery in less than 1 year ("Patient Perspective—Angela, Bell’s Palsy").

**Patient Perspective**

Angela, Bell’s Palsy

I woke up that Thursday morning with the same intense pain in my forehead that I had been experiencing for the past week. When I rolled out of bed, I realized that I didn’t have morning breath (or so I thought). Knowing that I had not brushed my teeth yet, I proceeded to do so and noticed that I could not taste the toothpaste. The fruit cup I ate for lunch tasted like Clorox. I chomped up and down on each bite, then carefully attempted to swallow. It was like I had been injected with several shots of Novocain. My throat felt like it had closed up, and each swallow took a concentrated effort. Over the course of eating my fruit, I managed to bite my tongue three times.

I was 35 weeks pregnant and on strict bedrest due to pregnancy-induced hypertension and severe edema (which later spiraled into toxemia). We attributed the numbness in my mouth to the edema. I had already swollen up like a balloon and had experienced intense numbness in my extremities since the 12th week of pregnancy. As the afternoon progressed, I grew more and more concerned. I knew something was not quite right. By 5:30 that evening, I had lost control of the entire left side of my face. I called my obstetrician, and she said to get to the ER because I was either having a stroke or had developed Bell’s palsy. The doctor at the ER confirmed that I had Bell’s palsy and prescribed Valtrex and prednisone to treat it.

The symptoms of Bell’s that I experienced were severe pain in my forehead, not being able to breathe out of the left side of my nose, and difficulty chewing, swallowing, and saying most consonants. I completely lost the ability to smile, blink, close my eye, raise my eyebrow, or use a straw or blow. My eyesight in the left eye blurred, and I could not go out at night due to the intense pain behind my eye triggered by headlights and having to use eyedrops every 5 to 20 minutes.

I delivered my baby (after induction, 2 days of labor, 2 hours of pushing, and emergency C section) 2 weeks after being diagnosed with Bell’s palsy. During labor, I continuously asked for my eyedrops and the pain in my head was so fierce that it overshadowed the contractions.

After delivery, I was desperate for my face to be “fixed.” I tried everything that anyone suggested: herbal supplements, chiropractic, facial massage, laser treatments, facial exercise, shock treatments, a neurologist consultation, and physical therapy. The only thing that has worked for me is time (and lots of it)!

For the first 15 weeks after being diagnosed, I wanted to hide from the world. However, here it is...
Chapter 50  Nursing Care of Patients With Peripheral Nervous System Disorders

Diagnostic Tests
History of the onset of symptoms is used to diagnose Bell’s palsy. Observation of the patient confirms the diagnosis. EMG may be done. The possibility of a stroke must be ruled out.

Therapeutic Measures
Prevention of complications is the goal of treatment. Prednisone may be given over 7 to 10 days to decrease inflammation. Antiviral agents such as acyclovir may be used to fight the virus and can shorten the course of the disease. Analgesics are given for pain control. Moist heat and gentle massage to the face and ear also ease pain. A facial sling can be used to aid in eating and support of facial muscles.

Nursing Process for the Patient with a Cranial Nerve Disorder (Trigeminal Neuralgia and Bell’s Palsy)

DATA COLLECTION. Assess attacks using the WHAT’S UP? format, being sure to include factors that trigger pain. Are sensory or motor problems associated with the pain? Assess the effect of the disorder on the patient’s life, including nutritional status, general and oral hygiene, behavior, and emotional state. Carefully document all findings.

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.

Acute Pain related to inflammation or compression of the nerve

EXPECTED OUTCOME. The patient will state pain is controlled at an acceptable level.
- Assess pain level and response to interventions as needed. Assessment guides intervention.
- Administer medications as needed for pain. Anticonvulsant and antidepressant agents used to treat neuropathic pain must be given routinely to prevent pain. Medications prevent or decrease pain and increase comfort.
- Discuss and implement alternative and complementary pain relief measures to complement medications and increase patient’s control over pain.
  - Biofeedback
  - Diversional activities
  - Plan hygiene activities when pain relief is at its peak to decrease discomfort with activities.
  - Provide alternative communication methods. The patient may not be able to speak clearly or want to speak due to pain.
    - Paper and pencil/pen
    - Dry erase board
    - Communication board
    - Pain scales for pointing to level of pain.
- Teach the patient to chew on the opposite side of the face to avoid triggering pain and injury.
- Encourage use of an electric razor rather than blades to prevent injury to numb areas.
- Provide measures for trigeminal neuralgia to reduce pain triggers.
- Provide soft cloths for facial hygiene using lukewarm water.
- Avoid touching the patient’s face.
- Provide a soft bristle toothbrush for oral care.
- Teach patient to protect face from cold or wind.
- Provide measures for Bell’s palsy to reduce pain and prevent muscle atrophy.
  - Provide warm, moist compresses prn.
  - Massage face.
  - Assist with facial exercises as prescribed by physical therapy.
  - Provide a facial sling.

Imbalanced Nutrition: Less Than Body Requirements, related to fear of triggering pain as evidenced by poor intake, weight loss

EXPECTED OUTCOME. The patient will maintain sufficient nutrition as evidenced by stable weight.
- Weigh patient twice weekly and record to monitor weight loss or gain.
- Provide small, frequent meals to promote nutrition without increasing pain.
- Provide soft, easy-to-chew foods at lukewarm temperature to prevent triggering pain.
- Provide a high-protein and high-calorie diet. Protein and calories are needed for cellular repair.
- Avoid hot or cold foods and drinks. Temperature extremes can trigger pain. If foods are associated with pain, the patient may avoid them.
- Encourage oral hygiene after each meal and at bedtime to prevent gum and tooth disease as triggers for pain.
- Insert a feeding tube as ordered on unaffected side if nutrition is severely impaired and without injury.
- Teach patient to wear glasses or goggles, especially when outside or in areas with particles in the air, to protect the eyes.

Risk for Injury to Eyes related to inability to blink (Bell’s palsy)

EXPECTED OUTCOME. The patient’s cornea will remain intact and without injury.
- Administer eyedrops or eye ointment as ordered by the HCP to protect the eye.
- Teach patient to use a patch over the affected eye to protect the eye.
- Advise patient to wear glasses or goggles, especially when outside or in areas with particles in the air, to protect the eyes.

EVALUATION. Nursing care has been successful if the patient reports that pain is controlled, nutrition is maintained with no inappropriate weight loss, and the eyes are intact and without injury. Table 50.4 summarizes and compares trigeminal neuralgia and Bell’s palsy.

---

**LEARNING TIP**

Remember! TN (cranial nerve V) is a sensory disorder; Bell’s palsy (cranial nerve VII) is a motor disorder.

**Home Health Hints**

- If a homebound patient has difficulty speaking (dysarthria), try using magnetic alphabet letters. Ask questions that require a yes or no answer. The patient can respond with the letter Y or N.
- Keep bedside commode lids up with patches of Velcro attached to the seat and the frame.
- Do a thorough nutritional assessment for patients with a history of trigeminal neuralgia to identify if there is a risk for malnutrition.
- Patients with trigeminal neuralgia may benefit from using a small spoon and softer foods for eating during periods of mild to moderate pain.
Chapter 50  Nursing Care of Patients With Peripheral Nervous System Disorders 1209

SUGGESTED ANSWERS TO CRITICAL THINKING

■ Jamie
1. Muscle weakness caused by myasthenia gravis improves with rest.
2. Have Jamie look up for 2 to 3 minutes. If ptosis occurs, have her close her eyes for several minutes. If she can open her eyelids and look up, myasthenia gravis is likely.
3. \[
\frac{2 \text{ mg}}{1 \text{ mL}} \times \frac{10 \text{ mg}}{1 \text{ mL}} = 0.2 \text{ mL}
\]
4. Team: nurse, OT, PT, neurologist, pharmacist, dietitian, and primary HCP for other health issues.

■ Mr. Miller
1. Priority nursing diagnoses include Ineffective Airway Clearance related to muscle weakness and Risk for Aspiration related to muscle weakness. If a patient’s respiratory system is compromised by a disease, nursing care should be focused on maintaining pulmonary function to preserve life.
2. Providing compassionate care to the patient and providing information about the disease and its prognosis to the patient and family establish an honest and supportive relationship. Support groups provide resources and emotional support.
3. Team: RN, respiratory therapy, speech pathologist, neurologist, dietitian. In addition, find out who at your institution helps patients make end-of-life decisions. A palliative care specialist or social worker can help the patient and family work through some difficult decisions and develop an advance directive.

REVIEW QUESTIONS

1. A patient with trigeminal neuralgia asks the nurse why carbamazepine (Tegretol) has been ordered. Which response is best?
   1. “It will help decrease the inflammation in your nervous system.”
   2. “It will depress your immune system, which can slow the progression of the disease.”
   3. “Carbamazepine is used to help relieve nerve pain.”
   4. “It is an anticonvulsant to prevent seizures.”

2. A patient with amyotrophic lateral sclerosis (ALS) expresses concern about not having enough breath to sing anymore. Which explanation by the nurse is best?
   1. “ALS can damage the nerves to your bronchi and bronchioles, causing constriction and reduced airflow.”
   2. “The demyelination of your nerves caused by ALS causes confusion in the impulses to your lungs.”
   3. “ALS can affect your vocal cords, making it difficult to form sounds as you speak or sing.”
   4. “ALS may be affecting the nerves that go to your respiratory muscles, making them weak.”

3. A patient who is newly diagnosed with ALS says to the nurse, “I do not want to be kept alive on machines.” Which nursing action is best in response?
   1. Ask the patient whether advance directives have been prepared and provide information if indicated.
   2. Reassure the patient that decisions about machines will not have to be made for a long time.
   3. Inform the patient that individuals with ALS are not candidates for artificial ventilation.
   4. Explain to the patient that a ventilator will be necessary to maintain respiratory function as the disease progresses.

4. When caring for a patient admitted with Guillain-Barré syndrome, which nursing diagnosis should take priority?
   1. Anxiety
   2. Imbalanced Nutrition
   3. Impaired Gas Exchange
   4. Impaired Mobility

5. Which nursing interventions are appropriate for the patient with Bell’s palsy? Select all that apply.
   1. Administer moisturizing eyedrops.
   2. Apply an eye patch.
   3. Avoid touching the patient’s face.
   4. Apply warm compresses.
   5. Provide facial massage.
   6. Teach the patient to protect the face from cool breezes.
UNIT THIRTEEN  Understanding the Neurologic System

6. Which meal would be the best choice for a patient with myasthenia gravis?
   1. Baked chicken sandwich, fresh carrots, apple
   2. Meatloaf, mashed potatoes, canned green beans
   3. Steak, baked potato, green salad
   4. Tacos, fresh vegetables, sliced peaches

7. How will the visiting nurse caring for a patient with myasthenia gravis and severe muscle weakness know if interventions have been effective?
   1. The patient verbalizes satisfaction with the plan of care.
   2. The patient states understanding of the medication regimen.
   3. The patient and family state that no further home visits are needed.
   4. The patient is able to perform ADLs with $\text{SaO}_2$ remaining at 95%.

LEARNING OUTCOMES

1. Describe the normal anatomy of the sensory system.
2. Explain the normal function of the sensory system.
3. List data to collect when caring for a patient with a disorder of the sensory system.
4. Identify diagnostic tests commonly performed to diagnose disorders of the sensory system.
5. Plan nursing care for patients undergoing diagnostic tests for sensory disorders.
6. Describe therapeutic measures for patients with disorders of the sensory system.
Our eyes and ears provide us with a great deal of sensory information. It is difficult to imagine what it would be like not to see or hear the world around us. Nurses have an important role in assessing vision and hearing. Patients depend on health care personnel to assist them in maintaining these primary senses. To learn more about ways to promote vision and hearing health, visit http://web.health.gov/healthypeople.

Chapter 51  Sensory System Function, Assessment, and Therapeutic Measures: Vision and Hearing

VISION

Normal Anatomy and Physiology of the Eye

External Structures

Several structures protect the eye from debris and desiccation (extreme dryness; Figs. 51.1 and 51.2).

Eyebrow: Perhaps the most significant role of the eyebrows is to enhance facial expressions, aiding in nonverbal communication. They also help keep perspiration out of the eye and shield the eye from glare.

Eyelids (palpebrae): Formed primarily by the orbicularis oculi muscle covered with skin, the eyelids protect the eye from foreign bodies and block light when closed to allow for sleeping. Periodic blinking also helps moisten the eyes with tears and wash out debris.

Conjunctiva: The conjunctiva is a transparent mucous membrane that lines the inner surface of the eyelid and covers the anterior surface of the eyeball (except for the cornea). It secretes a thin mucous film to help keep the eyeball moist. It is very vascular, which becomes apparent when eyes are “bloodshot”, a result of dilated vessels in the conjunctiva.

Palpebral fissure: This is the opening between the lids.

Tarsal glands: These glands, which lie along the thickened area at the edge of the eye (called the tarsal plate), secrete oil to slow the evaporation of tears and help form a barrier seal when the eyes are closed.

Lacrimal gland: This small gland secretes tears that flow onto the surface of the conjunctiva. Tears clean and moisten the eye's surface and also deliver oxygen and nutrients to the conjunctiva. Furthermore, tears contain a bacterial enzyme called lysozyme that helps prevent infection.

Lacrimal punctum: This is a tiny pore through which tears drain into the lacrimal canal and the nasolacrimal duct.

Nasolacrimal duct: This passageway carries tears into the nasal cavity (which explains why crying or watery eyes can cause a runny nose).

**Structure of the Eyeball**

Most of the eyeball is within the orbit, the bony socket that protects the eye from trauma. The six extrinsic muscles that move the eyeball are attached to the orbit and to the outer surface of the eyeball. There are four rectus muscles that move the eyeball side to side or up and down, and two oblique muscles that rotate the eye. The cranial nerves that innervate these muscles are the oculomotor, trochlear, and abducens (third, fourth, and sixth cranial nerves, respectively). Actions of the six extrinsic eye muscles not only allow voluntary control of movement but also will be innervated by the autonomic nervous system to perform convergence, an alignment of the visual axis of each eye on the same field of view.

The wall of the eyeball has three layers: the outer fibrous tunic (sclera and cornea), the middle vascular tunic (choroid, ciliary body that suspends the lens, and iris), and the inner nervous tunic (retina; Fig. 51.3). The lens divides the interior of the eye into two main cavities: anterior cavity and posterior cavity (Fig. 51.4). Anterior to the lens is the ring-shaped curtain called the iris, which divides the anterior cavity into two chambers: anterior chamber and posterior chamber.

The retina lines the posterior two-thirds of the eyeball and contains the photoreceptors (rods and cones). Rods detect only the presence of light, whereas cones respond to photons of differing wavelengths. The fovea centralis is a small depression in the macula lutea of the posterior retina, directly behind the center of the lens, and contains only cones. It is, therefore, the area of most acute color vision. Rods are proportionately more abundant toward the periphery of the retina, and for this reason night vision is best at the sides of the visual field.

Neurons called ganglion cells transmit the impulses generated by the rods and cones. These neurons all converge at the optic disc and pass through the wall of the eyeball as the optic nerve. The optic disc may also be called the blind spot because no rods or cones are present.

**Physiology of Vision**

Vision involves the focusing of light rays on the retina and the transmission of the subsequent nerve impulses to the visual areas of the cerebral cortex.

The refractive structures of the eye are, in order, the cornea, aqueous humor, lens, and vitreous humor. The lens is the only adjustable part of this focusing system. When the eye shifts focus to an object that is near, accommodation of the lens occurs (Fig. 51.5). Also, the pupil will constrict in near vision to force photons through the thickness of the lens (Fig. 51.6). Accommodation and pupil constriction increase the number of photons that strike the fovea centralis.

When photons strike the retina, they stimulate chemical reactions in the rods and cones. Resultant changes generate a nerve impulse for transmission. Rods generate an action potential in dim light but only allow shades of gray vision. The cones are specialized to respond to a portion of the visible spectrum.
The space between the lens and the cornea is the anterior cavity. This cavity is further divided into an anterior chamber (anterior to the iris) and a posterior chamber (posterior to the iris but anterior to the lens). A clear, watery fluid called aqueous humor fills the anterior cavity.

The posterior cavity is the larger cavity lying posterior to the lens. It is filled with a jelly-like substance called vitreous humor. This semi-solid material helps keep the eyeball from collapsing.

The lens is a transparent disc of tissue just behind the pupil, between the anterior and posterior cavities. The lens changes shape for near and far vision.

Anterior chamber
Canal of Schlemm
Posterior chamber

The nearly parallel light rays from distant objects require little refraction. Consequently, the ciliary muscle encircling the lens relaxes and the lens flattens and thins.

The more divergent light rays from a nearby object require more refraction. To help focus the light rays, the ciliary muscle surrounding the lens contracts. This narrows the lens, causing it to bulge into a convex shape and thicken, giving it more focusing power.

light spectrum; there are red-absorbing, blue-absorbing, and green-absorbing cones. Differing combinations of three cone types allow interpretation of color (Fig. 51.7).

Refraction inverts the image onto the photoreceptors in the retina. The impulses from the rods and cones are transmitted to the ganglion neurons, which con verge at the optic disc and become the optic nerve. The optic nerves from both eyes converge at the optic chiasma, just in front of the pituitary gland. Here, the medial fibers of each optic nerve cross to the other side. This crossing permits each visual area to receive impulses from both eyes, which is important for binocular vision.

The visual areas are in the occipital lobes of the cerebral cortex. It is here that the upside-down retinal images are righted and the slightly different pictures from the two eyes are integrated into one image; this is binocular vision, which also provides depth perception.

Aging and the Eye

The most common changes in the aging eye are those in the lens (Fig. 51.8). With age, the lens may become partially or totally opaque. The lens also loses its elasticity with age; most people become farsighted as they age and by 40 years begin to need corrective lenses. Peripheral vision losses may occur. Depth perception decreases and glare intensifies, both of which can affect safety. Color vision fades with lesser discrimination of blue, green, and violet colors. Red, yellow, and orange colors are best visible.
**The pupillary dilator** looks like the spokes of a wheel. When stimulated by the sympathetic nervous system, this muscle contracts, pulling the inside edge of the iris outward. This widens the pupil and admits more light.

**The pupillary constrictor** muscle encircles the pupil. When stimulated by the parasympathetic nervous system, the muscle constricts, narrowing the pupil to admit less light.

---

**Nursing Assessment of the Eye and Visual Status**

Nursing assessment of the eye begins with the collection of subjective data, then moves to observation and testing, and finally, a more invasive physical examination. Licensed practical nurses/licensed vocational nurses (LPN/L VNs) usually assist the health care provider (HCP) in conducting invasive data collection.

**Health History**

The nurse asks about family history that may affect vision, particularly glaucoma, diabetes, blindness, and cataracts. Many eye disorders are genetically transmitted, so this information alerts the nurse to potential alterations in eye health. Patients are asked about their general health and diseases such as diabetes and hypertension. A patient medication review looks for any ocular (eye) effects. Then, the nurse asks the patient about any changes in visual acuity or symptoms of abnormality (Table 51.1).

**Physical Examination**

**VISUAL ACUITY.** Objective data collection begins by checking the patient’s visual acuity (Table 51.2). Visual acuity is measured in a variety of ways but usually starts with the use of **Snellen’s chart**, an E chart, or a handheld visual acuity chart (Rosenbaum’s card) to test near and far vision. Snellen’s chart...
visual acuity chart is used to indicate visual acuity by having the patient hold the card approximately 14 inches from the eyes. The test is conducted and documented in the same way as the Snellen’s and E chart examinations.

**Visual Fields by Confrontation.** The examiner also tests peripheral vision, which is the ability of the eye to see objects peripherally while the eye is fixed or kept in one position. This is also known as testing visual fields by confrontation. To do this, the examiner compares his or her own ability to see peripheral objects with that of the patient. This test should be done with an examiner who has normal peripheral vision. The examiner stands 2 feet in front of, and facing, the patient and instructs the patient to cover one eye. The examiner covers his or her own corresponding eye (the eye that is aligned with the patient’s eye; e.g., if the patient’s right eye is covered, the examiner’s left eye is covered). The examiner uses the arm opposite the covered eye, extends it to the space midway between the patient and the examiner, and brings it toward the eye from three directions: superior, inferior, and temporal (middle). The examiner wiggles the finger while moving the arm. The examiner asks the patient to look straight ahead and indicate at what point he or she is able to see the examiner’s finger. One eye is tested and then the other. The patient has full visual fields if the point at which the patient sees the finger matches that at which the examiner sees it. The examiner documents the results as “visual fields equal to examiner,” “full visual fields,” or, if abnormal, “visual fields unequal to examiner in . . .” (identify position, e.g., left superior).

**Muscle Balance and Eye Movement.** The examiner tests extraocular muscle balance and cranial nerve function by instructing the patient to look straight ahead and follow the examiner’s finger movement without moving his or her head. As with the confrontation test, the patient and examiner face each other either standing or sitting. The examiner moves his or her finger in the six cardinal fields of gaze, coming back to the point of origin between each field of gaze (Fig. 51.10). If the patient’s eyes are able to follow the examiner’s finger in all fields of gaze without nystagmus, the patient is assessed to have adequate extraocular muscle strength and innervation. Nystagmus is an involuntary, cyclical, rapid movement of the eyes in response to vertical, horizontal, or rotary movement.

The corneal light reflex test assesses muscle balance. This test is conducted by shining a penlight toward the cornea while the patient is staring at an object straight ahead. The light reflection should be at exactly the same place on both pupils. If the eyes lack symmetry, muscle weakness could be present.

The cover test is used in conjunction with an abnormal corneal light reflex test to evaluate muscle balance. The patient is asked to look straight ahead at a far object. The examiner covers one of the patient’s eyes with a 3 × 5 card. The uncovered eye should have a steady gaze; if it moves, there may be muscle weakness. Next, the cover is quickly removed and the action of this eye is observed. If this eye moves to fixate on the light instead of staring straight ahead, it indicates a drifting of the eye when it was covered, which is a sign of muscle weakness. This deviation of the eye away from the light is called a cover test. If the eye returns to its original position, there is no nystagmus.

</table>
from the visual axis is known as tropia. Deviation of the eye toward the nose is known as esotropia, movement laterally is known as exotropia, and downward deviation is hypotropia.

**PUPILLARY REFLEXES.** When observed, the pupils should be round, symmetrical, and reactive to light. To test pupillary response to light, both consensual and direct examinations should be completed. A slightly darkened room works best. The patient is asked to look straight ahead, and the size of the pupil is noted. A penlight is shone toward the pupil from a lateral position, and the movement of the pupil is observed. The pupil should quickly constrict. The size of the pupil is noted when it constricts. This is known as direct response.

To conduct a consensual pupil examination, observe the eye just tested for reaction while shining the penlight into the other eye. The observed pupil should constrict. This is known as **consensual response.** Then repeat the procedure for the opposite eye.

The examiner proceeds to test for **accommodation,** which is the ability of the pupil to respond to near and far distances.

The patient is told to focus on an object far away. The size and shape of the pupils are observed. The examiner continues to observe the pupils as the patient focuses on a near object (the examiner’s penlight or finger) held approximately 5 inches from the patient’s face. Normally, the patient’s eyes turn inward and the pupils constrict. These responses, convergence and constriction, are called accommodation (“Gerontological Issues—Age-Related Changes in Vision and Hearing”). Examiners use the acronym PERRLA to indicate pupils equal, round, reactive to light, accommodation. If accommodation is not tested along with the other tests, the examiner may use the acronym PERRL.

**Gerontological Issues**

**Age-Related Changes in Vision and Hearing**

**Vision**

Older adults commonly have the following changes in their vision:

- Presbyopia, an inability to focus up close because of decreased elasticity in the ocular lens
- Narrowing of the visual field and more difficulty with peripheral vision
- Decreased pupil size and responsiveness to light
- Difficulty with vision in dimly lit areas or at night (requires more light to see adequately)
- Increased opacity of the lens, which causes sensitivity to glare, blurred vision, and interference with night vision
- Yellowing of the lens, which reduces ability to differentiate low-tone colors of blues, greens, andviolets (yellow, orange, and red hues are more clearly visible)
- Distorted depth perception and difficulty correctly judging the height of curbs and steps
- Decreased lacrimal secretions

Because visual accommodation decreases with aging, older adults have an increased risk of falling. An older person has difficulty making a visual adjustment when moving from a well-lit room into the evening darkness, for example, or when stepping out of a dark area into the sunlight.

The increased time needed to accommodate to near and far, dark and light, is often the reason that older adults do not drive at night. Usually the y say that light from oncoming traffic blinds them or that their eyes do not focus properly.

One of the simplest and most effective ways to improve vision for older adults is to ensure that eyeglasses are clean.
Hearing
Presbycusis is an age-related change in which progressive hearing loss is caused by loss of hair cells and decreased blood supply to the ear, resulting in a decreased ability to hear high-frequency sounds. Deafness or decreased hearing acuity is one of the main reasons that older adults withdraw from social activities. The loss of high-pitched hearing causes the older adult to hear distracting background noises more clearly than conversation.

Older adults who are deaf may need adaptive equipment in their home for safety. The use of a hearing aid can increase hearing for those who do not have nerve damage deafness. The use of flashlights instead of buzzers or alarms increases the safety of an older adult who is not able to hear a smoke detector or fire alarm.

INSPECTION AND PALPATION OF EXTERNAL STRUCTURES.
The extraocular structures are inspected beginning with the eyebrows. The presence of eyebrows, symmetry, hair texture, size, and extension of the brow are noted. The examiner inspects and palpates the orbital area for edema, lesions, puffiness, and tenderness. Then the eyelids are inspected for symmetry, presence of eyelashes, eyelash position, tremors, flakiness, redness, and swelling. The patient is asked to open and close the eyelids. When open, the eyelid should cover the iris margin but not the pupil. The distance between the upper and lower eyelid, known as the palpebral fissure, is inspected; it should be equal in both eyes. If the palpebral fissure is nonsymmetrical, observe for ptosis, a drooping of the eyelid, which is commonly seen in stroke patients. Next the medial canthus of the lower lid is gently palpated and observed for exudate. The eyelids are palpated for nodules while the eye is palpated for firmness over the closed eyelid.

The lower eyelid is pulled down, and the patient is asked to look upward. The conjunctiva and sclera are inspected for color, discharge, and pterygium (thickening of the conjunctiva). To inspect the upper eyelid, the upper lid is everted (turned inside out) over a cotton-tipped applicator. The patient blinks to return the eyelid to its resting position when the inspection is complete.

The external eyes are inspected for color and symmetry of the irises, clarity of the cornea, and depth and clarity of the anterior chamber. Shining a light obliquely across the cornea allows the practitioner in the examination. To perform the internal eye examination, specialized equipment must be used. It is useful, but not always necessary, to have the pupil dilated for the internal eye examination. Having a dark room allows the pupil to dilate, as does the application of anticholinergic mydriatic (causing dilatation) eyedrops.

The handheld instrument with a light source used to examine the internal eye is called an ophthalmoscope. The ophthalmoscope magnifies the internal structures of the eye, so the examiner can visualize the retina, optic nerve, blood vessels, and macula. The patient is asked to hold the head still with the eyes focused on a distant object and informed that the bright light might be uncomfortable. The ophthalmologist can also examine the internal eye using a stationary device called a slit-lamp microscope. For this, the patient is seated and rests the chin on a support while a microscope and light source are directed into the eye.

Intraocular Pressure. Estimation of intraocular pressure is measured by one of several types of tonometer. Often, the procedure is performed with anesthetic drops being instilled. One type of tonometry testing uses a puff of air to make an indentation in the cornea to measure intraocular pressure. Readings above the normal range may indicate glaucoma.

Diagnostic Tests for the Eye
There are a number of diagnostic tests for the eye, including bacterial culture, digital imaging, optical coherence tomography, fluorescein or indocyanine green angiography, electroretinography, ultrasonography, and other imaging tests.

Eye Culture
If exudate from any portion of the eye or surrounding structure is present, an eye culture may be ordered. Results of the culture determine if anti-infective treatment is necessary.

Digital Imaging
Digital imaging is a newer way of viewing the retina without requiring the use of dilating eyedrops. The instrument takes a digital picture of the retina in 2 seconds. The majority of the retina is viewable and assists in early detection of eye disease. It provides a permanent photographic reference for the retina.

Optical Coherence Tomography (OCT)
OCT takes a picture of the retina. It is safe, fast, and does not have the risks associated with the use of dye. Light beams are shone into the eye at various angles and the amount of interference is measured creating a detailed image of the depth of the retina.

Fluorescein or Indocyanine Green Angiography
Angiography with dye is a test using special cameras to find leaking or damaged blood vessels in the retinal or deeper choroidal circulation. Fluorescein is a yellow dye that glows in visible light and is useful for showing the retinal circulation, and indocyanine green is a green dye that shows up with invisible infrared light to highlight the choroidal circulation.
The patient is assessed for dye allergies (indocyanine green contains iodine) before the procedure. Then the pupil is dilated and the dye is injected into the patient’s venous system where it travels to the eye’s circulation to make the blood vessels there visible. Fluorescein is used in diabetic retinopathy and retinal vascular disease. Indocyanine green is useful for the wet form of macular degeneration when blood is present in the macula.

**Electroretinography**

Electroretinography is useful in diagnosing diseases of the rods and cones of the eye. The procedure evaluates differences in the electrical potential between the cornea and retina in response to light wavelengths and intensity. The test is conducted by placing contact lenses with electrodes directly on the eye.

**Ultrasoundography**

Ultrasound is useful when the internal eye cannot be visualized directly because of obstructions such as corneal opacities or bloody vitreous. The eye is anesthetized with instillation of anesthetic drops, and a transducer probe is placed on the eye to perform the ultrasound.

**Imaging Tests**

X-ray films show bone structure and tumors. Computed tomography (CT) and magnetic resonance imaging (MRI) visualize ocular structures and abnormalities of the eye and surrounding tissues.

**Therapeutic Measures for the Eye and Vision**

Nurses have an important role in screening and educating individuals, families, and the community about the care for healthy eyes and prevention of disease. To learn more about ways to promote vision health, visit www.lighthouse.org. For resources to help those persons who are blind, visit the American Foundation for the Blind at www.afb.org or the National Federation of the Blind at www.nfb.org.

**Regular Eye Examinations**

People who are not known to have visual deficits and do not have diseases associated with visual loss, such as diabetes, should have their eyes examined at regular intervals throughout their life. Screening tests usually are done during an annual physical examination to detect gross visual defects. Patients who wear corrective lenses or have disease processes that place them at risk for visual loss should have their eyes examined by an eye care provider at least yearly.

Eye care providers include the ophthalmologist and optometrist. An ophthalmologist is a physician who specializes in the comprehensive care of the eyes and visual system, including diagnosing and treating eye diseases. An optometrist specializes in eye examinations to identify visual defects, diagnosis problems, prescribe corrective lenses or other treatments, and refer for medical treatment. The optometrist is not a physician but is identified as a doctor of optometry. An optician is a person trained to grind and fit lenses according to prescriptions written by the ophthalmologist or optometrist.

**Eye Hygiene**

It is important to keep debris out of the eyes to prevent scratching of the eye’s delicate surfaces. When a foreign object gets into the eye, such as dirt or an eyelash, the person should be taught not to rub the eye but to allow tears to wash out the object. This can be done by pulling the eyelids down over the eye for a brief time. When wiping the eyes, the nurse should wipe from the inner canthus to the outer canthus.

**Nutrition for Eye Health**

Adequate nutrition is important for eye health (“Nutrition Notes”). Eye disorders related to inadequate vitamin intake include corneal damage and night blindness from lack of vitamin A and optic neuritis as a result of vitamin B deficiency.

**Eye Safety and Prevention of Injury**

Many people in the United States suffer eye injuries each year. Activities such as microwave cooking, lawn care, and shooting rubber bands and BB guns all contribute to eye injury. Many of these injuries could be prevented with education and implementation of safety measures (Table 51.3).

**Eye Irrigation**

If it is necessary to irrigate foreign bodies or chemical substances out of the eye, the nurse prepares the patient by explaining the

**Nutrition Notes**

**Nutrition and Eye Disease**

In some developing countries, vitamin A deficiency is a leading cause of preventable blindness and the leading cause of childhood blindness. In developed countries, antioxidants have been investigated in relation to cataracts and age-related macular degeneration (AMD), to conditions that can also lead to severely impaired vision. Little evidence supports a role for antioxidants in preventing cataracts, and further research efforts along that line are discouraged. Research on AMD is ongoing. Evidence suggests that antioxidant vitamin and mineral supplementation may delay the progression of AMD in people already diagnosed with the disease. Other risk factors for AMD are modifiable obesity-related risk factors, notably low physical activity and serum lipid levels.

**Recommendations**

The value of specific foods or nutrients in preventing eye disease has not been proven. If a person chooses to take supplements, a multivitamin and multimineral product at recommended dietary allowance levels is advocated rather than separate preparations of individual nutrients. Other choices should be made in consultation with the patient’s HCP.
procedure. An isotonic solution is usually used. It is delivered onto the eye using intravenous (IV) tubing or a Morgan lens (Box 51-1 and Fig. 51.11).

**Guide Dogs for the Blind and Visually Impaired**

Special guide dogs are trained to lead blind and visually impaired people around obstacles. Generally they are allowed in places where animals are banned such as stores or restaurants. While the dogs are working, they should not be approached, touched, or fed without their owner’s permission.

**Medication Administration**

A variety of drugs are available for eye application. Most are applied as drops, ointments, or irrigations. The nurse must know the usual dosage and strength, desired action, side effects, and contraindications of the medication being administered to prevent harm to the patient. Systemic adverse reactions can occur, and diseases can be exacerbated from the administration of eye medications. Older adults are especially susceptible to this because they have more chronic diseases, as well as use ophthalmic agents long term. These agents can interact with other medications the patient is taking. So the nurse observes patients for possible reactions.

Chapter 52 discusses specific ophthalmic medications and their uses. To identify the steps in the application of eye medications, see Boxes 51-2 and 51-3. Whenever eye medications, especially eyedrops, are administered, the punctum (tear duct) of the eye should have pressure applied to it by either the nurse wearing gloves or the patient, if able, for at least 1 minute or longer as directed. This reduces systemic absorption of the medication through the punctum. Some eye medications can have serious cardiac or respiratory effects, and patients have had life-threatening reactions to them. The nurse should teach the patient the proper instillation of eye medications to reduce these reactions.

**TABLE 51.3 EYE SAFETY AND INJURY PREVENTION**

<table>
<thead>
<tr>
<th>To Protect From</th>
<th>Use These Eye Safety Measures</th>
</tr>
</thead>
</table>
| **Foreign objects** | Wear safety goggles.  
Avoid mowing over rocks or sticks.  
Always wear safety goggles when using lawn edging yard devices. |
| **Chemical splashes** | Use splash shields when working with chemicals such as cleaning solution or body fluids.  
Close eyes to avoid getting hair spray in them. |
| **Corneal lens abrasions/infections from contact lenses** | Follow manufacturer’s or eye care professional’s directions for length of use and cleaning procedures.  
Do not overwear lenses. |
| **Ultraviolet light (UV)** | Wear ultraviolet-protected sunglasses when outdoors.  
Instruct patients to wear sunglasses with side shields after administration of mydriatics.  
Wear a hat to shield sun. |
| **Visual deficits in adult with corrective lenses** | Update prescription of glasses yearly.  
Glasses should fit properly, be clean, and be free of scratches. |
| **Eye strain from computer usage** | The position of the bottom of the monitor should be 20 degrees below the line of sight and should be positioned 13 to 18 inches from the eyes.  
The light in the room should prevent glare.  
Increase the font size on the screen if letters appear too small.  
If dry eyes are a problem while using a computer, adjust the monitor to a lower level so the eyes do not have to open as wide, which increases evaporation. |
| **Eye injury from sports** | Wear protective eyewear with polycarbonate lenses.  
Wear facemasks or helmets while participating in any high-contact or high-impact sports. |

**NURSING CARE TIP**

Older patients, when instilling their own eyedrops, may not feel the drops go in. Teaching patients to refrigerate the drops, if not contraindicated, for 15 to 30 minutes before instillation helps them feel if the drops go into the eye or on the face.
Box 51-1 Eye Irrigation

1. Explain procedure to patient.
2. Perform hand hygiene.
3. Gather equipment. For low-volume irrigation, a prefilled squeezable bottle is used. For large-volume irrigation, an IV bag of isotonic solution such as normal saline or lactated Ringer’s solution is used. Attach IV tubing to the bag and flush the line.
4. Apply anesthetic drops, if ordered.
5. Place a basin by side of patient’s head and pad area with towels to absorb irrigant.
6. Apply gloves.
7. Eye may be irrigated by holding distal end of IV tubing at inner canthus of the eye, or a Morgan lens may be attached (see Fig. 51.11). Lens is placed directly on the anesthetized eye, and tubing is connected to IV bag tubing. Proceed with irrigation using a slow, steady stream of irrigant. Generally, use of the Morgan lens is more comfortable for patients because eyelids do not need to be held open.
8. Assess patient’s tolerance to the procedure.
9. Remove Morgan lens if used.

Box 51-2 Administration of Eyedrops

1. Explain procedure to patient. Contact lenses should be removed. They should not be worn if eyes are reddened, and for 10 minutes after drops have been instilled or as directed.
2. Assess allergies, and check medication dosage, strength, side effects, contraindications, and expiration date. Do not use if solution is cloudy.
3. Perform hand hygiene and apply gloves.
4. Avoid touching tip of dropper to anything to avoid contamination that could cause an eye infection. Do not wash or rinse dropper.
5. Instruct patient to tilt head backward and look up toward the ceiling.
6. Gently pull lower lid down and out to form a pocket to catch eyedrop.
7. Approach patient’s eye from the side and instill prescribed amount of medication into the pocket. It is helpful (including for patient who is self-administering eyedrops) to use the forehead as a stabilizing area for the hand administering the drop.
9. Apply gentle pressure with a tissue to the punctum (over the tear duct) for at least 1 to 5 minutes to keep medication from being systemically absorbed. Nurse or patient can do this.
10. Wipe excess medication off eyelids or cheek.
11. If another eyedrop is to be given, wait 5 to 10 minutes before administering.
12. Remove gloves. Perform hand hygiene.

Box 51-3 Administration of Eye Ointment

1. Explain procedure to patient.
2. Check medication for dosage, strength, side effects, contraindications, and expiration date.
3. Perform hand hygiene and apply gloves.
4. Instruct patient to tilt head backward and look up toward the ceiling.
5. Gently pull lower lid down to form a pocket into which ointment is placed.
6. Express ointment directly into exposed palpebral conjunctiva, moving from inner to outer canthus. Be careful not to touch patient’s eye or surrounding structure with tip of ointment tube. The tip of the ointment tube must remain sterile.
7. Release lower eyelid over the ointment.

EYE PATCHING. After treating an injured or infected eye, the physician may order the eye to be patched. The nurse applies ointment or drops if ordered, asks the patient to keep the eyelid shut, and then places a disposable, cotton gauze eye patch over the depression of the eye socket. If the patient has a deep eye socket, the nurse may need to place two pads over the socket.
to help the eyelids remain closed. The purpose of eye patching is to protect the eye from further damage by keeping the lids closed. Sometimes an additional metal shield is placed over the soft pads to protect the eye from external injury. The patch is taped in place and the patient instructed to rest the eyes. The nurse should suggest quiet activities, such as listening to music or an audio book, or sleeping. Watching television or reading is not recommended because the patched eye follows the movement of the unpatched eye.

**HEARING**

### Normal Anatomy and Physiology of the Ear

The ear consists of three areas: the outer ear, the middle ear, and the inner ear. The inner ear contains the receptors for the senses of hearing and equilibrium.

**Outer Ear**

The outer ear consists of the auricle and the auditory canal (Fig. 51.12).

**Middle Ear**

The middle ear is an air-filled cavity in the temporal bone. Vibrations of the tympanic membrane caused by sound are transmitted through the three auditory bones (ossicles). The stapes then transmits vibrations to the fluid-filled inner ear at the oval window.

**Inner Ear**

The inner ear is a cavity in the temporal bone called the bony labyrinth, lined with membranes called the membranous labyrinth. The fluid between bone and membrane is called perilymph, and that within the membrane is called endolymph. The structures of the bony labyrinth include the semicircular canals, vestibule, and cochlea (Fig. 51.13).

The process of hearing involves the transmission of vibrations and the generation of nerve impulses. When sound waves enter the auditory canal, vibrations are transmitted by the following structures: tympanic membrane, malleus, incus, stapes, oval window of the inner ear, perilymph and endolymph within the cochlea, and hair cells of the organ of Corti. When the hair cells bend, they generate impulses that are carried by the eighth cranial nerve to the brain. The auditory areas, for both hearing and interpretation, are in the temporal lobes of the cerebral cortex.

The inner ear also has receptors for equilibrium: dynamic equilibrium receptors are within the semicircular canals whereas static equilibrium receptors are within the vestibule (Fig. 51.14). Within the utricle and saccule of the vestibule, the hair cells bend in response to gravity on the otoliths as the position of the head changes. The impulses generated are carried by the vestibular branch of the eighth cranial nerve to the cerebellum, medulla, and pons. The cerebellum sends this information continuously to the cerebral motor cortex. The cerebellum and brainstem use this information to maintain equilibrium at a subconscious level; the cerebrum interprets the conscious awareness of the position of the head.

When the head moves, movement of the endolymph will bend the cupula within the ampulla. The bending of the hair cells at its base generates impulses carried by the vestibular branch of the eighth cranial nerve to the cerebellum and brainstem, and then impulses are sent to the cerebral cortex. These impulses are interpreted as directional acceleration or deceleration; this information is used to maintain equilibrium during movement.

### Aging and the Ear

In the ear, cumulative damage to the hair cells in the organ of Corti usually becomes apparent sometime after the age of 60 (see Fig. 51.8). Damaged hair cells cannot be replaced. Ability to hear high frequencies is usually lost first (presbycusis), whereas hearing may still be adequate for lower pitched ranges. The high-pitched sounds f, s, k, and sh are common losses. Also, it becomes more difficult to filter out background noises, so busy, loud environments make it difficult to hear conversations.

### LEARNING TIP

Presbycusis is the loss of hearing high-pitched sounds (pitch = cycles per second; loudness = decibels [dB]). Because the ability to hear pitch is lost rather than loudness, it is not helpful to talk louder to a patient with this type of hearing loss. In fact, talking louder can make it more difficult to discriminate sounds. It is important to know the type of hearing loss a patient has.

### Nursing Assessment of the Ear and Hearing

A quiet environment is helpful for collecting accurate hearing data. Document the patient’s behavior because it may provide information related to hearing loss.

### Health History

The patient’s self-appraisal of his or her hearing or related symptoms is obtained during the health history. Data collection regarding symptoms includes asking the **WHAT’S UP?** questions: where it is, how it feels, aggravating and alleviating factors, timing, severity, useful data for associated symptoms, and perception of the problem by the patient. Symptoms related to the ear that may be reported include decreased

### UNIT FOURTEEN

**Understanding the Sensory System**

---

**Box 51-3 Administration of Eye Ointment—cont’d**

8. Instruct patient to gently close eyes.
10. Explain that vision may be blurred while ointment is in the eye.
Chapter 51  Sensory System Function, Assessment, and Therapeutic Measures: Vision and Hearing

Outer Ear

The auricle (pinna) is the visible part of the ear. Shaped by cartilage, this part of the ear funnels sound into the auditory canal.

The auditory canal leads through the temporal bone to the eardrum. (The opening of the auditory canal to the outside of the body is called the external acoustic meatus.) Glands lining the canal produce secretions that mix with dead skin cells to form cerumen (ear wax). Cerumen waterproofs the canal and also traps dirt and bacteria. The cerumen usually dries and then, propelled by jaw movements during eating and talking, works its way out of the ear.

The malleus, incus, and stapes are the auditory ossicles. These bones are the smallest in the body. The malleus is a hammer shape, the incus is an anvil, and the stapes is a stirrup. The stapes fits within the oval window of the vestibule, which is where the inner ear begins.

Tympanic membrane (or eardrum): This membranous structure separates the outer ear from the middle ear; it vibrates freely in response to sound waves.

Middle Ear

Auditory ossicles: The three smallest bones in the body connect the eardrum to the inner ear; they are named for their shape:
- Malleus (hammer)
- Incus (anvil)
- Stapes (stirrup)

The stapes fits within the oval window of the vestibule, which is where the inner ear begins.

The auditory or eustachian tube is a passageway from the middle ear to the nasopharynx. Its purpose is to equalize pressure on both sides of the tympanic membrane. Unfortunately, it can also allow infection to spread from the throat to the middle ear.

hearing or loss of hearing, otorrhea (discharge), otalgia (ear pain), itching, fullness, tinnitus (ringing, buzzing, or roaring in the ears), or vertigo (dizziness).

Information about current and past medications is obtained. Many medications are potentially toxic to the ear and can cause hearing loss or decreased hearing. Pay particular attention to any exposure to medications that are potentially ototoxic, such as certain antibiotics or diuretics (see Chapter 52).

Ask about hearing aids or assistive hearing devices, surgeries, treatments, allergies, sodium and alcohol intake (which can affect the amount of endolymph in the inner ear), and childhood illnesses including mumps, measles, or scarlet fever. Also ask about recent upper respiratory infections, history of infections, injury to the ear, hospitalizations, swimming habits, exposure to pressure changes (flying or diving), medical diseases, and any recent or past exposure to any loud noises.

Family history related to ear disorders includes any hearing problems or hearing loss and family members with Ménière’s disease. Significant findings are recorded, including the patient’s relationship to the family member with the problem.

Information about the patient’s care of the ears is also gathered. It is important to assess what preventive measures the patient practices and what the patient’s learning needs are concerning care and protection of the ears. Determine how the patient cleans the ears, any exposure to loud noises during

• WORD • BUILDING •

otorrhea: oto—related to the ear + rhea—to flow
otalgia: ot—related to the ear + algia—signifying pain
ototoxic: oto—related to the ear + toxic—poison
The organ of Corti consists of a layer of epithelium (composed of sensory and supporting cells). Thousands of hair cells project from this epithelial layer and are topped with a gelatin-like membrane called the tectorial membrane. Nerve fibers extending from the base of the hairs eventually form the cochlear nerve (cranial nerve VIII).

Resting on the floor (called the basilar membrane) of this duct is the organ of Corti, the hearing sense organ.

The spirals of the cochlea are divided into three compartments. The middle compartment is a triangular duct (called the cochlear duct) filled with endolymph; the outer two compartments are filled with perilymph.

Inside the vestibule are two sense organs: the utricle and saccule. A patch of hair cells lies inside both these organs. The tips of the hair cells are covered by a gelatin-like material; embedded throughout the gelatin material are heavy mineral crystals called otoliths.

Three fluid-filled semicircular canals lie at right angles to one another. This arrangement allows each canal to be stimulated by a different movement of the head.

At the end of each canal is a bulb-like area called an ampulla. Within each ampulla is a mound of hair cells topped by a gelatinous cone-shaped cap called the cupula. The lightweight cupula floats in the endolymph that fills the semicircular canals.
recreational or work activities, any changes in ability to hear, and any exposure to ototoxic medications. Determine if the patient has had a hearing evaluation and if there is a history of ear problems (Table 51.4). On the basis of these findings, instruct the patient in ways to care for the ears and maintain ear health.

**Physical Examination**

Physical examination of the ear begins by observing the behaviors of the patient (Box 51-4). Note how the patient communicates. Observe how the patient talks, noting any slurred speech or words. Examination of the ear includes inspection, palpation, testing auditory acuity, balance testing, and, for the advanced practitioner, otoscopic examination (Table 51.5).

**INSPECTION AND PALPATION OF THE EXTERNAL EAR.** Inspection of the external ear begins with examining the auricle. The external ear should be inspected for size, symmetry, configuration, and angle of attachment. Note any obvious deformities or scars. The skin should be smooth and without breaks, particularly behind the ear in the crevice. The color should be uniform, without signs of inflammation. To inspect the external ear canal, tip the adult patient’s head to the side and use a penlight or otoscope to inspect the canal. Any drainage or cerumen (wax), including the color, odor, and clarity of the drainage. The skin should be smooth and without inflammation, edema, or breaks. There should be no lesions, foreign bodies, erythema, or edema in the external ear canal. Inspection of the external ear canal should be completed before obtaining an infrared ear temperature because the presence of cerumen can alter the accuracy of the reading.

Next the auricles are palpated and any tophi, lesions, or masses noted. Tophi are deposits of uric acid crystals that appear as small, hard nodules in the helix (external ear margin); they may also occur in gout. The auricle should be nontender when it is palpated; tenderness can indicate an external ear infection. A downward protrusion of the helix, called Darwin’s tubercle, is a normal finding. The mastoid process should be smooth and hard when palpated. The mastoid process can be of different sizes but should not be tender or swollen.

*Continued*
Do you hear better out of one ear than the other?
Have your friends or family commented on your decreased hearing?
Do you wear a hearing aid or other assistive device?
If so, what is the device and for which ear is it used?
How does your hearing loss affect your daily life?
Do you feel embarrassed or frustrated because of your hearing loss?
How do your friends and family react to your hearing loss?
Are you exposed to loud noises, such as with your current or past job, busy traffic, machinery, or loud music?

Hearing loss can cause social isolation.
Can cause damage to the ear leading to hearing loss over time.

**Box 51-4 Behaviors Indicating Hearing Loss**

Adults with hearing loss may show any or all of the following behaviors:
- Turns up volume on the television or radio.
- Frequently asks, “What did you say?”
- Leans forward or turns head to one side during conversations to hear better.
- Cups hand around ear during conversation.
- Mentions that people are talking softly or mumbling.
- Speaks in an unusually quiet or loud voice.
- Answers questions inappropriately or not at all.
- Has difficulty hearing high-frequency consonants.
- Avoids group activities.
- Shows loss of sense of humor.
- Has strained or serious look on face during conversations.
- Appears to ignore people or is aloof; does not participate.
- Is irritable or sensitive in interpersonal relations.
- Reports ringing, buzzing, or roaring noise in the ears.

**AUDITORY ACUITY TESTING.** Auditory function can be grossly evaluated using three assessment tests. The whisper voice test is one test to check hearing function in each ear. The patient occludes one ear with a finger, and the nurse stands 1 to 2 feet away on the opposite side. The nurse whispers two-syllable words toward the unoccluded ear. The patient restates the whispered words. The nurse should be by the patient’s side to prevent the patient from lip reading. The nurse’s voice can be increased from a soft, medium, or loud whisper to a soft, medium, or loud voice. The process is repeated on the other ear. The patient is asked if hearing is better in one ear than in the other ear. The patient should be able to hear a soft whisper equally well in both ears. Findings of one ear hearing better than the other or an inability to hear a soft whisper can be indicative of hearing impairment. Results of the test are documented.

A second acuity test is the **Rinne test.** This test is performed with a tuning fork and is useful for differentiating between conductive and sensorineural hearing loss. To perform the test, strike the tuning fork and place it on the patient’s mastoid process (Fig. 51.15). Verify that the patient is able to hear the tuning fork, and then instruct the patient to say immediately when the sound is no longer heard. When the patient indicates that the sound is no longer heard, place the vibrating tuning fork 2 inches in front of the ear (see Fig. 51.15). Ask the patient if he or she hears the tuning fork and then to indicate when the sound is no longer heard. Normally, air conduction (AC) is heard twice as long as bone conduction (BC). The patient reports this by hearing the tuning fork when placed in front of the ear (AC) after no longer hearing it when placed on the mastoid process (BC). Normal results are recorded as “AC greater than BC.” The test is repeated on the other ear and findings recorded. Abnormal findings can indicate conduction or sensorineural problems (Table 51.6).

<td>Internal otoscope examination is completed by experienced practitioner and should reveal a slightly conical, shiny, smooth, pearly gray eardrum.</td>
<td></td>
</tr>
<tr>
<td>Other</td>
<td>Observe the patient’s position and posture during the interview and physical exam.</td>
<td>Behaviors may indicate hearing loss and the patient’s effort to compensate.</td>
</tr>
<tr>
<td></td>
<td>Does the patient watch the examiner’s mouth or lean toward the examiner?</td>
<td>The patient may be unaware of the behaviors.</td>
</tr>
</tbody>
</table>

The **Weber test** is a third test to assess hearing acuity. The Weber test is also performed using a tuning fork. Place the vibrating tuning fork on the center of the patient’s forehead or head (Fig. 51.16). Verify that the patient can hear the tuning fork. If the patient gives a positive answer, ask the patient if the sound is heard better in the left ear, better in the right ear, or the same in both ears. It is important to give the patient three choices from which to choose. Normally, the patient hears the sound the same in both ears (see Table 51.6).

**Balance Testing.** When the patient reports dizziness, nystagmus, or problems with equilibrium, simple tests can be performed to assess vestibular function. The first test is simply to observe the patient’s gait by having the patient walk away from the examiner and then walk back. Note the
patient’s balance, posture, and movement of arms and legs. The patient should be able to walk in an upright position with no difficulties in balance or movement.

**Romberg’s test**, or falling test, is another simple test to assess vestibular function. Instruct the patient to stand with feet together, first with eyes open and then with eyes closed. Normally, the patient has no difficulty maintaining a standing position with only minimal swaying. If the patient has difficulty maintaining balance or loses balance (a positive Romberg test), the patient may have an inner ear problem. If a fall appears likely, be prepared to support the patient to prevent injury.

**Otoscopic examination.** An otoscope is an instrument consisting of a handle, a light source, a magnifying lens, and an optional speculum for inserting in the ear. Some otoscopes have a pneumatic device for injecting air into the canal to test the eardrum’s mobility and integrity. The otoscope is used to visualize the external ear, ear canal, and tympanic membrane. Otoscopic examination is completed to identify specific disorders or infections, remove wax, or remove foreign bodies. Examination of the ear canal should be completed during insertion and removal of the speculum. The ear canal should be smooth and empty. There should be no redness, scaliness, swelling, drainage, nodules, foreign objects, or excessive

wax (see “Evidence-Based Practice”). The internal otoscopic examination is conducted to examine the eardrum and is done by the HCP. The eardrum should appear slightly conical, shiny, and smooth and be a pearly gray color.

EVIDENCE-BASED PRACTICE

Clinical Question
Does cerumen removal affect cognition?

Evidence
Three cerumenolytic agents were compared for removal of cerumen, and the effect of cerumen removal on cognition was assessed. Thirty-eight older-adult subjects (mean age: 78 years) were treated. A statistically significant difference between the Raven’s standard progressive matrices (measures test takers reasoning ability) score before and after the removal of cerumen was found.

Implications for Nursing Practice
Ensuring that the ear canal is kept clear of cerumen is important to the well-being of older adults.

REFERENCE

Diagnostic Tests for the Ear and Hearing

Audiometric Testing

Audiometric testing is used as a screening tool to determine the type and degree of hearing loss. An audiologist conducts the hearing tests in a soundproof booth. The audiometer produces a stimulus that consists of a musical tone, pure tone, or speech. To test air conduction, the patient is placed in the booth, wears earphones, and signals the audiologist when and if the tone is heard. Each ear is tested separately as the patient is exposed to sounds of varying frequency or pitch (hertz) and intensity (decibels). By varying the levels of the sound, a hearing level is established (Table 51.7). The use of earphones measures air conduction, level of speech hearing, and understanding of speech. During bone conduction testing, a vibrator is placed on the mastoid process and the earphones are removed. Testing proceeds as with air conduction.

A patient with normal hearing should have the same air conduction as bone conduction hearing levels. Alterations in testing air and bone conduction hearing can provide information about the location and type of hearing loss.

Tympanometry

Tympanometry is a test used to measure compliance of the tympanic membrane and differentiate problems in the middle ear. Varying amounts of pressure are applied to the tympanic membrane, and the results create a distinctive response recorded on a graph called a tympanogram. The test is useful in determining the amount of negative pressure within the middle ear. The patient is informed that the tympanometry may cause transient vertigo. The patient should report any nausea or dizziness experienced during the test.

Caloric Test

The caloric test is used to test the function of the eighth cranial nerve and to assess vestibular reflexes of the inner ear that control balance. The test is performed first on one ear and then the other. Warm (112°F [44.5°C]) or cold (86°F [30°C]) water is instilled into the ear canal. This stimulates the endolymp of the semicircular canals, which stimulates movement of the head. Nystagmus is a normal response. The patient may also feel dizzy. No nystagmus is seen if the patient has a disease of the labyrinth such as Ménière’s disease. The test is contraindicated if the patient has a perforated tympanic membrane. Otoscopic examination should be completed before this test to assess for excessive cerumen or perforated tympanic membrane.

Electronystagmogram

The electronystagmogram is used to diagnose the causes of unilateral hearing loss of unknown origin, vertigo, or ringing in the ears. It is similar to the caloric test. The test is usually completed in a darkened room. Five electrodes are taped to the patient’s clean face at certain positions around the eye. The electrodes measure nystagmus in response to vestibular stimulation. Measurements are taken at rest, looking at different objects, with eyes open and closed, in different positions, with water of different temperatures, and with air. Usually

| Pain threshold          | 130 dB  |
| Firearms                | 140 dB  |
tranquilizers, alcohol, stimulants, and antivertigo agents are held for 1 to 5 days before the test. The patient should also avoid tobacco and caffeine on the day of the test. The test is contraindicated in patients who have pacemakers. The patient may experience nausea, vertigo, or weakness following the test.

**Computed Tomography**

CT is useful for visualizing the temporal and mastoid bones, the middle and inner ears, and the eustachian tube.

**Magnetic Resonance Imaging**

MRI allows the membranous organs, nerve, and blood vessels of the temporal bone to be examined for disease.

**Laboratory Tests**

**EAR CULTURE.** Culture of drainage from the ear canal or surgical incision is important in diagnosis and treatment of acute infections. Identifying the organism responsible for the infection allows the appropriate antibiotic to be used. Often with chronic infections, the culture is less helpful because Gram-negative bacilli cover up the original pathogen. Drainage from the external ear is collected using a sterile cotton-tipped or polyester-tipped swab. Samples should be taken to the laboratory immediately.

**PATHOLOGY EXAMINATION.** Pathology examination of tissue obtained during surgery is completed to rule out a malignancy and identify any unusual problems. A cholesteatoma (cyst of epithelial cells and cholesterol found in the middle ear) is usually documented by a pathology examination.

**Therapeutic Measures for the Ear and Hearing Medications**

The medications most often used to treat ear disorders include anti-infectives, anti-inflammatories, antihistamines, decongestants, cerumenolytics, and diuretics. Anti-infectives can be administered systemically or as a topical solution. Ear medications are generally in a liquid form for ease in administration as drops (Box 51-5 and Fig. 51.17). Anti-inflammatories, antihistamines, and decongestants are used with acute infections to reduce nasal and middle ear congestion. Cerumenolytics are used to soften cerumen and remove it from the ear canal. Diuretics are used with some inner ear disorders to reduce pressure caused by fluids.

**Box 51-5 Administration of Eardrops**

1. Explain procedure to patient.
2. Check medication for dosage, strength, side effects, contraindications, and expiration date. Make sure medication is at room temperature.
3. Perform hand hygiene and apply gloves.
4. Position patient sitting up with head tilted toward unaffected side or lying down on the unaffected side.
5. For a child, pull auricle down and back. For an adult, pull auricle up and back.
6. Instill prescribed number of drops, being careful not to touch tip of dropper to anything to prevent contamination.
7. Have patient remain in position for 2 to 3 minutes.
8. A small cotton plug may be inserted to prevent medication from running out of ear.
10. Document eardrop administration and patient’s tolerance of procedure.

**CRITICAL THINKING**

**Mr. Frank**

At a physician’s office visit, Mr. Frank’s wife expresses concern about his changing behavior during the last 6 months. She reports that Mr. Frank no longer enjoys talking to neighbors or visiting with friends in their church group, is irritable, has lost his sense of humor, and does not always answer her questions appropriately.

1. What do you suspect is happening with Mr. Frank?
Ear Health Maintenance

Safe routine cleaning and care of the ears should be taught to all patients (Fig. 51.18). Patient education should include prevention of trauma, prevention of hearing loss, and early detection of hearing loss. All patients can benefit from this type of education, as found in Table 51.8.

Assistive Hearing Devices

Hearing aids are instruments that amplify sound (see Chapter 52). Certain hearing aids may be designed to amplify sounds and attenuate certain portions of the sound signal. A small battery serves as the energy source. Digital hearing aids contain computers that convert sound waves into numerical codes, before amplifying. This provides clearer and crisper sound that is programmable to each person’s hearing loss. Digital hearing aids are more expensive than analog (convert sound waves into electrical signals for amplifying) hearing aids. Three types of hearing aids are commonly used today:

1. The in-the-ear aid fits into the ear. It is small and unobtrusive to the wearer and others.
2. The canal aid fits into the ear canal and is nearly unseen.
3. New technology for assistive devices is being used or developed that involves the use of Bluetooth and smart phones. Several amplification apps are available.

To care for a hearing aid, ensure that it is turned off and the battery is removed when it is not in use. This reduces battery expense for the patient, who may be on a fixed income. When turning the hearing aid on, the volume should be turned up just until it squeals and then turned down until the patient indicates it is at the appropriate level for hearing. At least weekly, clean the hearing aid mold portion with either a dry cloth or a damp, soapy cloth and rinse with a damp cloth. A brush may come with the hearing aid for cleaning, or a cotton-tipped swab can be used to clean the small tip that fits into the ear.

Other types of assistive hearing devices are middle ear implants and cochlear implants. The middle ear implant (see www.vibrant-medel.com) is for those with a sensorineural hearing loss. It provides sound perception by enhancing the normal middle ear hearing function. A person who is profoundly deaf and has lost all hearing may use a cochlear implant, which is placed surgically. Cochlear implants feature a microelectronic processor for converting the sound into electrical signals, a transmission system to relay signals to the implanted parts, and a long, slender electrode placed in the cochlea to deliver the electrical stimuli directly to the fibers of the auditory nerve.

Safety products are available to help people with hearing impairments. These include visual-alarm smoke detectors, such as a flashing light, or alarms that vibrate the bed as a means to alert a person with a hearing impairment of a fire.

Guide Dogs for the Deaf and Hearing Impaired

Hearing ear dogs are trained to respond to sounds that the person who is hard of hearing cannot hear. Examples include a crying baby, oven timer, and smoke alarm. These dogs provide a valuable service that enriches the lives of those with hearing problems.

SUGGESTED ANSWERS TO CRITICAL THINKING

■ Mr. Frank

1. He is exhibiting behaviors of hearing loss.
2. Ear inspection, a whisper voice test, a Rinne test, and a Weber test might be performed.
3. For inspection of ear, cerumen impaction may be found. For a whisper voice test, the whisper is not heard in affected ear. For a Rinne test, bone conduction is heard longer than air conduction in affected ear. For a Weber test, sound is heard louder in affected ear.

5. Explaining to Mr. and Mrs. Frank symptoms of hearing loss will help them understand Mr. Frank’s behaviors. Explore with them the effects of these symptoms in daily life to develop plans for coping with the hearing loss until an intervention is implemented.
6. Mr. Frank may not hear telephones or alarms such as smoke or carbon monoxide detectors, so alternatives such as visual alarms could be considered. If he drives, he may not hear car horns or emergency vehicles of which he should be aware so he can compensate.
Chapter 51  Sensory System Function, Assessment, and Therapeutic Measures: Vision and Hearing

REVIEW QUESTIONS

1. In what order does a beam of light pass through the refractive structures in the eye? (Use all items, and place them in the correct order.)
   1. Aqueous humor
   2. Cornea
   3. Lens
   4. Vitreous humor

2. The nurse is asked to assist with the assessment of a patient’s visual fields. Which assessment method does the nurse anticipate will be used?
   1. Inspection using an ophthalmoscope
   2. Fluorescein angiography
   3. Vision test using Snellen’s chart
   4. Comparison of the patient’s visual fields with the nurse’s own

3. Which patient behavior would the nurse expect to find in the health history of a patient who has a hearing loss?
   1. Turns volume lower on the television.
   2. Is irritable or sensitive in interpersonal relations.
   3. Answers questions appropriately.
   4. Mentions that people talk too loudly

4. The nurse is collecting data during a patient’s clinic visit. Which question will best collect data about a patient’s preventive ear health?
   1. “What symptoms are you having?”
   2. “Tell me about your ear pain.”
   3. “When was your last hearing evaluation?”
   4. “What medications do you take?”

5. The nurse is assisting with a Romberg’s test. What is the most important nursing intervention during the Romberg’s test?
   1. Ensure patient safety.
   2. Whisper softly into each ear.
   3. Ensure a quiet environment.
   4. Remove all cerumen from ear canal.

6. The nurse teaches a patient about ear care. Which patient statement indicates to the nurse that the patient understands the ear care teaching?
   1. “I should insert a cotton swab into my ear canal for cleaning.”
   2. “I should not get my external ear wet during bathing.”
   3. “I should block one nostril when blowing my nose.”
   4. “Aspirin can be toxic to the ears.”

7. The nurse prepares to provide an eye irrigation to a patient with a methicillin-resistant Staphylococcus aureus (MRSA) infection. Contact precautions are ordered. Which of the following protective items will the nurse need while performing this procedure? Select all that apply.
   1. Gloves
   2. Gown
   3. Goggles
   4. Mask
   5. Shoe protectors
   6. Sterile gloves

8. A patient is taking aspirin. Which finding would indicate to the nurse that the patient is experiencing a toxic effect related to the medication?
   1. Halos around lights
   2. Decreased night vision
   3. Tinnitus
   4. Vertigo

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Explain the pathophysiology of each of the disorders of the sensory system.
2. Define blindness and the refractive errors of vision.
3. Explain the etiologies, signs, and symptoms of each sensory disorder.
5. Identify therapeutic measures for each sensory disorder.
6. Identify medications contraindicated for patients with acute angle-closure glaucoma.
7. List three ototoxic drugs.
8. List data to collect when caring for patients with disorders of the sensory system.
9. Plan nursing care for patients with disorders of the eye or ear.
11. Discuss how to know if nursing interventions for sensory disorders have been effective.
VISION DISORDERS

Early detection of visual problems can reduce their impact. Nurses play an important role in assisting the patient with visual problems (Table 52.1).

Infections and Inflammation

Infections and inflammation of the eye and surrounding structures can be bacterial or viral in origin. The eye may become aggravated by allergens, chemical substances, or mechanical irritation, leading to infection by microorganisms. Mechanical irritation may be caused by sunburn or bacterial infection. Inflammation results from allergens to environmental substances or by irritation of chemical irritants found in perfumes, makeup, sprays, or plants. Viral agents that cause infection include herpes simplex, cytomegalovirus, and human adenovirus. Bacterial agents that infect the eye include Staphylococcus and Streptococcus ("Cultural Considerations").

Conjunctivitis

Conjunctivitis is inflammation of the conjunctiva caused by either a virus or a bacterium. Viral conjunctivitis occurs more commonly than bacterial conjunctivitis and is highly contagious. The virus is usually transmitted via contaminated eye secretions on the hand that then touches or rubs an eye, infecting that eye. The virus is Hardy and may live on dry surfaces for 2 weeks or more. Viral conjunctivitis lasts 2 to 4 weeks. Bacterial conjunctivitis (commonly called pinkeye) usually is due to staphylococcal or streptococcal bacteria and is also highly contagious. Conjunctivitis can also be caused by the organisms Haemophilus influenzae, Chlamydia trachomatis, and Neisseria gonorrhoeae. Conjunctivitis is commonly transmitted among children and then to family members. Signs and symptoms of conjunctivitis include conjunctival redness and crusting exudate

Cultural Considerations

Vision

Trachoma, a form of conjunctivitis, is a common, chronic disease that affects millions of people worldwide. It is primarily seen among low-income persons in the Mediterranean, Africa, Brazil, and the Far East. Trachoma is caused by a viral strain of Chlamydia trachomatis that is highly contagious. Following the acute conjunctivitis phase, the eyelids shrink as a result of scarring. The shrinking tends to pull the eyelashes inward (entropion), which may scratch the cornea. In addition, granulations form on the inner eyelids. This painful condition may eventually lead to corneal ulceration and blindness. Trachoma is medically treated with topical and oral erythromycin or tetracycline.
on the lids and in the corners of the eyes, itching, pain, and excessive tearing.

Viral conjunctivitis is treated by supportive measures, which seek to keep the patient comfortable until the infection resolves on its own. Treatment includes eyewashes or eye irrigations, which cleanse the conjunctivas and relieve the inflammation and pain. Bacterial conjunctivitis is treated with antibiotic eye drops or ointments (Table 52.2). Adults generally prefer eye drops because they do not impair vision. Ointments are commonly used when the eye is resting (at night) or in children, who may squeeze their eyes shut and cry when ocular medications are applied, thus expelling the medication. With either type of conjunctivitis, hand hygiene is the best means of preventing the spread of the disease.

**Blepharitis**

Blepharitis, an inflammation of the eyelid margins, is a chronic inflammatory process. The cause may include staphylococcal infection, seborrhea (dandruff), rosacea (a chronic disease of the skin usually affecting middle-aged and older adults), dry eye, or abnormalities of the meibomian glands and their lipid secretions. There are two types of blepharitis: seborrheic blepharitis and ulcerative blepharitis. Seborrheic blepharitis is characterized by reddened eyelids with scales and flaking at the base of the lashes. Ulcerative blepharitis produces crusts at eyelashes, reddened eyes, and inflamed corneas. Eyelids chronically infected with *Staphylococcus* may become thickened, and eyelashes may be lost. Treatment requires a commitment to long-term daily cleansing with cotton-tipped swabs dipped in

*Continued*
diluted baby shampoo or sterile eyelid cleanser solutions to prevent infection. If infection occurs, antistaphylococcal antibiotic ointment (bacitracin, erythromycin) is applied to the lid margins one to four times a day after the eyelids have been cleansed. Warm compresses may also be used.

**Hordeolum and Chalazion**

Another type of eyelid infection is a **hordeolum**. An external hordeolum (sty) is a small staphylococcal abscess in the sebaceous gland at the base of the eyelash (either the glands of Zeis or glands of Moll). Styes are small, raised, reddened areas. Use of cosmetics on the eyes may contribute to hordeolum formation. A second type of abscess, a **chalazion** (internal hordeolum), may form in the connective tissue of the eyelids, specifically in the meibomian glands. A chalazion is larger than an external hordeolum. Styes may be tender; however, a chalazion often puts pressure on the cornea, causing more discomfort. Hordeolums usually form and drain spontaneously within a few days and require no treatment. Chalazions may require surgical incision and drainage (I&D) if they do not drain spontaneously. If either type of abscess persists, administration of oral antibiotics may be prescribed along with application of warm compresses to aid healing.

**Keratitis**

**PATHOPHYSIOLOGY AND ETIOLOGY.** Keratitis is inflammation of the cornea and may be acute or chronic and superficial or deep. The depth of keratitis is determined by the layers of the cornea that may be affected. Keratitis may be associated with bacterial conjunctivitis, a viral infection such as herpes simplex, a corneal ulcer, or diseases such as tuberculosis and syphilis. Herpes simplex keratitis is the most common corneal infection in developed countries, with bacterial and fungal infections being more prevalent throughout the rest of the world. People who have dry eyes, wear contact lenses and practice poor contact lens hygiene, have decreased corneal sensation, or are immunosuppressed are at increased risk of keratitis.

**SIGNS AND SYMPTOMS.** The cornea has many pain receptors, so any inflammation of the cornea is painful. This pain increases with movement of the lid over the cornea. Other symptoms of keratitis include decreased vision, **photophobia** (sensitivity to light), tearing, and blepharospasm (spasm of the eyelids). The conjunctiva often appears reddened. In advanced cases, the cornea may appear opaque (cloudy).

**DIAGNOSTIC TESTS.** Assessment of keratitis or corneal ulcer is made by use of a slit lamp or a handheld light. The cornea is examined by shining the light source obliquely (diagonally) across the cornea to show opacity in the cornea. Fluorescein stain may also be used to outline the area of involvement. When the stained area is viewed with a blue light, the disruption in the corneal surface shows up clear. If the patient is having pain from blepharospasm (contraction of the orbicularis oculi muscle), the examiner may instill a topical ophthalmic anesthetic such as proparacaine.

**THERAPEUTIC MEASURES.** Therapeutic interventions may include topical antibiotics, topical corticosteroids, topical interferons, antiviral medications for herpes simplex, cycloplegic agents (to keep the iris and ciliary body at rest), and warm compresses. If the cornea is severely damaged, corneal transplant may be required. The eye may be patched to decrease the amount of eyelid movement over the cornea during healing.

**COMPLICATIONS.** Corneal infections are usually serious and often threaten eyesight. The corneal tissue may become thin and susceptible to perforation. Untreated, keratitis can cause permanent scarring of the cornea, resulting in permanent loss of vision.

**Nursing Process for the Patient With Inflammation and Infection of the Eye**

**DATA COLLECTION.** Table 52.3 reviews the subjective data that is collected. Objective data collection includes the condition of the conjunctiva, eyelids, and e yelashes; the presence of exudate, tearing, any visible abscess on the palpebral border, or a palpable abscess in the eyelid; opacity of the cornea; and visual acuity testing comparing unaffected and affected eyes.

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.

**Acute Pain related to inflammation or infection of the eye or surrounding tissues**

**EXPECTED OUTCOME:** The patient’s pain will be decreased or absent as evidenced by lower rating on a pain scale.

- Assess the patient for pain. *Use of dark glasses, rubbing the eye, squinting, and avoiding light may be indicators of pain that should be assessed.*
- Administer eye medications (topical anesthetic drops or ointments, antibiotics, anti-inflammatory agents, or analgesics) as ordered *to relieve eye pain.*
- Apply warm or cool packs as ordered *to assist in soothing the eye.*
- Patching of the affected eye may help reduce pain by decreasing the movement of the eye across the eyelid.
- Explore additional methods of pain reduction, such as *guided imagery, relaxation techniques, music, or distraction.*

**Risk for Injury related to visual impairment**

**EXPECTED OUTCOME:** The patient will not experience injury as a result of visual impairment.

- Assess and plan for visual impairments that may be present *to promote safety.*
- Advise patient with one eye patched not to drive *to prevent injury because depth perception is altered.*
- Teach caution when ambulating and reaching for things to prevent injury because inflamed eyes often do not focus well and may have exudate, tearing, or ointment present, which can interfere with vision.

**Deficient Knowledge related to eye disease process, prevention, and treatment from lack of previous experience**

**EXPECTED OUTCOME:** The patient will be able to explain the disease process, prevention, and treatment measures. The patient will demonstrate the treatment regimen correctly, such as *administration of eye drops.*

- Teach patient prevention, care of the affected eye, medication administration, and safety issues *for understanding and adherence to therapeutic plan.*
- Have patient demonstrate the administration of ointments or drops after teaching has occurred to *evaluate understanding.*
- Teach patient and family how to prevent spreading infection if it is contagious.
- Teach patient proper eye hygiene to prevent further complications.
- Teach contact lens hygiene to prevent reinfection of the eye.
- Teach not to wear contact lenses when the eye or surrounding structure is inflamed to prevent irritation.

**EVALUATION.** The therapeutic measures have been successful if pain is reduced to an acceptable rating, vision improves or returns to preillness level, injury does not occur as a result of visual impairment, infection does not occur as a result of poor eye hygiene or wearing of contact lenses, patient explains disease process, prevention, or treatment regimen accurately, or prescribed treatment is stated or demonstrated correctly (e.g., administering eye drops or ointments).

HIV = human immunodeficiency virus.
Refractive Errors

Pathophysiology and Etiology

Refraction refers to the bending of light rays as they enter the eye. Emmetropia, or normal vision, means that light rays are bent to focus images precisely on the macula of the retina. Ametropia is a term used to describe an eye refractive error. When an image is not clearly focused on the retina, refractive error is present. Ametropia occurs when parallel light rays entering the eye are not refracted to focus on the retina. Refractive errors account for the largest number of impairments in vision. There are four common ametropic disorders: **hyperopia, myopia, astigmatism,** and **presbyopia.**

**HYPEROPIA.** Hyperopia (farsightedness) is caused by light rays focusing behind the retina (Fig. 52.1). People who are hyperopic see images that are far away more clearly than images that are close. Physiologically, the globe or eyeball is too short from the front to the back, causing the light rays to focus beyond the retina. Hyperopia is corrected with convex lenses.

**MYOPIA.** Myopia (nearsightedness) is caused by light rays focusing in front of the retina. The eyeball is elongated, and thus the light rays do not reach the retina. Distance vision is blurred but items close up are clear. Myopia is corrected with concave lenses (Fig. 52.1).

**ASTIGMATISM.** Astigmatism results from unequal curvatures in the shape of the cornea. When parallel light rays enter the eye, the irregular cornea causes the light rays to be refracted to focus on two different points. This can result in either myopic or hyperopic astigmatism. The person with astigmatism has blurred vision with distortion. The corneal irregularities can be caused by injury, inflammation, corneal surgery, or an inherited autosomal dominant trait.

**PRESBYOPIA.** Presbyopia is a condition in which the crystalline lenses lose their elasticity, resulting in a decrease in ability to focus on close objects. The loss of elasticity causes light rays to focus beyond the retina, resulting in hyperopia. This condition usually is associated with aging and generally occurs after age 40. If an individual has preexisting hyperopia, the onset of presbyopia may occur earlier than age 40. Likewise, if a person has myopia, presbyopia may correct the myopia by projecting the light rays directly on the retina. Because accommodation for close vision is accomplished by lens contraction, people with presbyopia exhibit the inability to see objects at close range. They often compensate for blurred close vision by holding objects to be viewed farther away. Reports of eyestrain and mild frontal headache are common. These symptoms are relieved with eye rest and corrective lenses.

**Signs and Symptoms**

People with refractive errors commonly report difficulty reading or seeing objects. Often, the eyestrain that occurs as one attempts to improve visual acuity causes headache.

**WORD BUILDING**

presbyopia: presby—old age + opia—concerning vision

---

**LEARNING TIP**

To remember the type of vision a person has, use this saying: You are what you say. For example, if you say you are farsighted, this means that you have clear vision of far away images, but difficulty seeing images that are nearer. If you say you are nearsighted, this means that you have clear vision of near images, but difficulty seeing images that are farther away.
Diagnostic Tests
A refractive error can be roughly estimated by use of Snellen’s chart. For definitive refractive error measurement, a retinoscopic examination is needed. Before this examination, a cycloplegic drug is often instilled (see Table 52.2). A cycloplegic drug dilates the pupil and temporarily paralyzes the ciliary muscle, thus preventing accommodation. During the examination, an ophthalmologist or optometrist examines the internal and external eye and uses trial lenses via a retinoscope to assess the type of lens best suited to correct the refractive error, which may differ in each eye. If a cycloplegic agent has been used, patients need to be told that blurred vision might be present and sunglasses worn until the agent wears off. In addition, the patient should be instructed that drier and reading might not be possible until the effect of the cycloplegic drug is gone.

Therapeutic Measures
Refractive errors are commonly treated with either eyeglasses or contact lenses. The corrective lenses bend the parallel light rays so that the y converge on the macular portion of the retina. Laser-assisted in situ keratomileusis (LASIK) and photorefractive keratectomy (PRK) are surgical procedures also used to correct refractive error. With LASIK and PRK, laser energy is applied to reshape the cornea. The cornea is made flatter for indi visions with myopia and more cone shaped for those with hyperopia.

Blindness
Blindness is the complete or almost complete absence of the sense of sight. Some people consider the terms blind and partially sighted to be negative and prefer the term visually impaired to describe their condition.

Pathophysiology and Etiology
Blindness in adults is caused by a variety of factors, including trauma, complications from various diseases such as hypertension and diabetes and conditions such as cataracts and glaucoma. Blindness is produced when the rays of light on their way to the optic nerve are obstructed, or by disease of the optic nerve or tract of the part of the brain connected with vision. Blindness may be permanent or transient, complete or partial, or may occur only in darkness (night blindness).

Signs and Symptoms
Aside from a general loss of vision, patients may describe their visual image as blurred, distorted, or absent in specific areas of the visual field. Objects may appear dark or absent around the peripheral field in glaucoma or retinitis pigmentosa. Retinitis pigmentosa is a degeneration of the pigmented layer of the retina. The center of the visual field may appear dark for indi visions with diabetic retinopathy or macular degeneration. Half the visual field may be impaired in patients with hemianopia. This results from a defect in the optic pathways in the brain and is often seen with stroke. Patients may report that the visual field appears blurry or hazy in corneal visual problems, cataracts, diabetic retinopathy, or refractive errors (Fig. 52.2).

Diagnostic Tests
Diagnostic tests may include a visual field examination, tonometry, and slit-lamp microscope examination. Retinal angiography is used to follow blood flow through the retinal vessels and to detect vascular changes. Ultrasoundography may be used to visualize changes in the posterior eye that cannot be directly examined because of other pathological conditions, such as a cloudy cornea, a bloody vitreous, or an opaque lens.

Therapeutic Measures
Therapeutic interventions for blindness center on treating the underlying condition and preventing further impairment. Treatment may include medications, surgical intervention, corrective eyewear, and referral to supportive services.

Nursing Process for the Patient With Visual Impairment
What do you think some of the challenges would be for a person who is blind?

DATA COLLECTION. Table 52.4 reviews the collection of subjective data. Collection of objective data involves observing the patient. Is there squinting? Rubbing of eyes? Is the patient using compensatory measures—magnifying glass, sitting close to television, using large-print reading materials, avoiding reading, using eyeglasses?

Psychosocial data are important because a blind person may be withdrawn or socially isolated, have low self-esteem or poor coping mechanisms, or have poor interpersonal skills as a result of the visual impairment.

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION. Nursing care begins by understanding how to interact with a patient who has a visual impairment (Box 52-1). A patient’s level of independence must be included in the planning phase. If patients have minimal visual impairment or have attended rehabilitation, they may be able to function independently. If a patient has recently become visually impaired, he or she may be completely dependent until alternative ways of coping with this impairment have been learned.

Planning focuses on meeting self-care needs, keeping the patient safe from injury, supporting the grieving process, and helping the patient acquire knowledge of agencies, services, and devices that allow maintenance of independence. Families must be included in the planning phase because they need to understand and be supportive...

- What part of the visual field is affected? If there is vision, what are the characteristics of what can be seen? Blurry? Hazy? Dark? Halos around lights?
- Is it worse when reading? Is it worse when watching TV? Does it affect the patient only at night? Is vision better at distances or close up?
- When did the symptoms start? Do they come and go? Is the impairment progressively getting worse? Was onset sudden?
- Does the impairment affect the patient’s activities of daily living? If so, how severely? Does the patient need assistance to cook, dress, bathe, read mail, pay bills, access health care, obtain transportation, maintain household, shop?
- Does the patient have diabetes, hypertension, a family history of retinitis pigmentosa, a history of eye infection, or eye trauma? Has the patient recently traveled out of the country?
- What does the patient think is wrong? How severe does the patient perceive the impairment to be?

of the self-image and role performance changes that may occur (see the “Nursing Care Plan for the Patient With Visual Impairment”). Referral to organizations that enhance the independence of people with visual impairments is helpful.

**EVALUATION.** The outcomes for a patient with a visual impairment are met if the patient demonstrates the ability to complete activities of daily living (ADLs) with increasing independence, remains free of injury, and demonstrates the ability to assess agencies and services for those with visual impairments.
Box 52-1 Interacting With a Patient Who Has a Visual Impairment

- People entering a room and at each contact with the patient should identify themselves.
- Post a sign on the door or over the bed that identifies the patient’s visual status so that others can interact appropriately.
- When walking with the patient, allow the patient to grasp an arm and walk a half step behind. Be aware of obstacles on either side when walking.
- Remember that the individual is not having hearing problems, so use a normal tone of voice and do not yell.
- Tell the patient when leaving the room or area so the patient does not continue conversation in an empty room, which may cause embarrassment.
- When orienting the patient to the hospital room, explain the location of items the patient may need, such as the water pitcher, call light, bed controls, urinal, and tissues. Attempt to keep these items in the same place at all times.
- If the patient has a seeing eye dog, do not play with the dog, pet it, or feed it without consulting the patient—the dog is working! Make sure the patient’s dog is near the bed, on a mat provided especially for the dog, preferably on the side of the bed that is less likely to be used by staff. Instruct staff and visitors about the seeing eye dog.
- When seating a patient, place the patient’s hand on the arm of the chair.
- People entering a room and at each contact with the patient should identify themselves.
- Post a sign on the door or over the bed that identifies the patient’s visual status so that others can interact appropriately.
- When walking with the patient, allow the patient to grasp an arm and walk a half step behind. Be aware of obstacles on either side when walking.
- Remember that the individual is not having hearing problems, so use a normal tone of voice and do not yell.
- Tell the patient when leaving the room or area so the patient does not continue conversation in an empty room, which may cause embarrassment.
- When orienting the patient to the hospital room, explain the location of items the patient may need, such as the water pitcher, call light, bed controls, urinal, and tissues. Attempt to keep these items in the same place at all times.
- If the patient has a seeing eye dog, do not play with the dog, pet it, or feed it without consulting the patient—the dog is working! Make sure the patient’s dog is near the bed, on a mat provided especially for the dog, preferably on the side of the bed that is less likely to be used by staff. Instruct staff and visitors about the seeing eye dog.

NURSING CARE PLAN for the Patient With Visual Impairment

**Nursing Diagnosis:** Dressing and Feeding Self Care Deficit related to altered vision.

**Expected Outcome:** The patient will demonstrate ability to perform ADLs, with assistance if necessary.

**Evaluation of Outcome:** Patient is able to perform ADLs as independently as possible.

**Intervention** Identify patient’s ability to perform activities of daily living such as dressing and feeding.

**Rationale** Determines patient’s ability to adequately dress and feed self. **Evaluation** Can patient dress and feed self independently? If not, what level of assistance is required?

**Intervention** Provide assistance with dressing and grooming as required such as pre-matching coordinated clothing for easy selection or selecting and laying coordinated clothing out for patient to dress.

**Rationale** Ensures patient’s dressing and grooming needs are met. **Evaluation** Is patient able to dress and groom self adequately?

**Intervention** Provide assistance with preparing food and feeding as required such as for severe vision loss use the face of a clock for referencing location of foods on a plate.

**Rationale** Ensures patient’s feeding needs are met. **Evaluation** Is patient able to eat as desired?

**Nursing Diagnosis:** Risk for Injury related to altered vision

**Expected Outcome:** The patient will remain safe from injury.

**Evaluation of Outcome:** The patient remains injury free.
NURSING CARE PLAN for the Patient With Visual Impairment—cont’d

**Intervention** Provide for optimal care of assistive appliances such as eyeglasses, including maintenance of proper prescription, fit, and cleaning. **Rationale** Improperly fitting or dirty eyeglasses may impair vision even further. Older adults should have their eyeglass prescription checked yearly. **Evaluation** Do eyeglasses fit properly? Are lenses clean? Is prescription current?

**Intervention** Structure environment to compensate for visual loss by adding color and contrast (e.g., chairs and carpeting should be in contrasting colors, bright tape or paint on stairs, medicine bottles color coded with colored dot stickers). **Rationale** Makes the environment easier to visualize and interpret and assists in depth perception and identifying medications. **Evaluation** Does the environment have clearly delineated walkways, sitting areas, and doorways? Are areas with changes in elevation clearly identified using contrasting tape or paint? Is there a way for patient to safely self-administer medications?

**Intervention** Structure environment to compensate for visual loss by use of large-print directional signs and arrows, well-lit areas, nonglare surfaces, consistent placement of objects, traffic areas free of clutter. **Rationale** Large directional signs assist the patient in maintaining orientation. Shiny floors or areas with bright window glass can impair vision. Traffic areas free of clutter assist in preventing injury. **Evaluation** Can the patient identify locations such as bathroom, dining room, and office areas? Can the patient ambulate freely without safety hazards?

**Intervention** Introduce other assistive devices such as handheld magnifying glasses, tableside magnifiers, television magnifiers, large-print items, and phone dial covers with large numbers, talking watches, alarm clocks, and calculators. **Rationale** Patients may not be aware of assistive devices that could help them adapt to vision loss and continue previous activities, such as watching TV or reading letters and magazines. Allows people to rely on hearing rather than vision. **Evaluation** Is patient aware of assistive devices that allow participation in previously enjoyed activities such as TV or reading? Is the patient able to pay bills? Read mail? Communicate on the telephone?

**Nursing Diagnosis:** Deficient Knowledge

**Expected Outcome:** The patient will understand resources that will allow maintenance of independence.

**Evaluation of Outcome:** The patient will identify resources that can be used to support independence.

**Intervention** Refer to specialized clinician such as ophthalmologist or occupational therapist or to specialized resources such as American Federation for the Blind or Prevent Blindness America. **Rationale** Specialized clinicians can provide detailed examination and treatment for the disorder. Specialized resource groups have networks in place to assist people in coping with loss and assisting with maximizing abilities. **Evaluation** Does patient know who to call for detailed examination and treatment of problems? Does patient know that there are specialized clinicians and resource groups to help with the visual impairment? Does patient know how to access these specialists?

Diabetic Retinopathy

**Pathophysiology and Etiology**

Retinopathy is a disorder in which vascular changes occur in the retinal blood vessels. It is most common in persons with diabetes. The pathological changes in diabetic retinopathy are related to excess glucose, changes in the retinal capillary walls, formation of microaneurysms, and constriction of retinal blood vessels. Three stages of diabetic retinopathy have been identified: background retinopathy, preproliferative retinopathy, and proliferative retinopathy.

Background retinopathy is the earliest stage, in which microaneurysms form on the retinal capillary walls. These microaneurysms may leak blood into the central retina or macula. If the leakage causes edema, the patient may notice a decrease in color discrimination and visual acuity.

The second stage, preproliferative retinopathy, is characterized by swollen and irregularly dilated veins, which results in sluggish or blocked blood flow. Patients generally are not aware of this stage because there are no symptoms.

Proliferative retinopathy, the third stage, is characterized by the formation of new blood vessels growing into the retinal and optic disc area in an attempt to increase the blood supply to the retina. The newly formed blood vessels are fragile and often leak blood into the vitreous and retina. In addition to leaking, the new vessels may grow into the vitreous, which causes a traction effect, pulling the vitreous away from the retina and subsequently pulling the retina a way from
Chapter 52 Nursing Care of Patients With Sensory Nervous System Disorders: Vision and Hearing

the choroid. This condition is called retinal detachment (discussed later).

**Signs and Symptoms**

There may be a reduction in central visual acuity or color vision as a result of macular edema (see Fig. 52.2). Many patients with diabetic retinopathy have no symptoms until the proliferative stage, at which point vision is lost. Visual loss at the last stage usually cannot be restored.

**Complications**

Early treatment for diabetic retinopathy is highly successful in preventing further visual loss; however, existing visual loss cannot be reversed. For this reason, it is very important for patients with diabetes to have a comprehensive eye examination through dilated pupils at least once each year or as directed by their health care provider (HCP). Careful control of diabetes during the first 5 years after diagnosis reduces occurrence and delays onset of diabetic retinopathy.

**Diagnostic Tests**

Diabetic retinopathy, as well as the other retinopathies, can be diagnosed only on examination of the internal eye. The examination is conducted with an ophthalmoscope following dilation of the pupil with a cycloplegic agent. The examination may be enhanced by use of retinoangiography. In the initial stages, vessels may appear swollen and tortuous (twisted).

**Therapeutic Measures**

Treatment of diabetic retinopathy focuses on stopping the leakage of blood and fluid into the vitreous and retina. The leaking microaneurysm is sealed by use of laser photocoagulation. Lasers can also be used to shrink the abnormal blood vessels. If blood has already leaked into the vitreous, a vitrectomy is performed. During a vitrectomy, the vitreous humor is drained out of the eye chamber and replaced with saline or silicon oil (oil often removed months later). The replacement fluid is necessary to support the structures of the eyeball until healing can occur. Use of intravitreal corticosteroids is beneficial.

**Nursing Process for the Patient With Diabetic Retinopathy**

**DATA COLLECTION.** Nursing data collection for diabetic retinopathy includes risk factors associated with the incidence of the disease. The patient may not have any symptoms. If people with diabetes do have changes in perceptions of visual acuity or color discrimination, they should immediately contact their HCP.

**NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION.** The planning phase of the nursing process for diabetic retinopathy focuses on prevention of visual loss by early detection and treatment. If the patient has entered phase three and is already visually impaired, the “Nursing Care Plan for the Patient With Visual Impairment” is used. Nursing diagnosis, goal, and intervention for diabetic retinopathy include but are not limited to the following:

**Risk for or Actual Ineffective Self Health Management**

**EXPECTED OUTCOME:** The patient will state ability to manage therapeutic regimen.

- Determine whether the patient with a visual impairment who is diabetic can monitor blood glucose and draw up and administer the correct amount of insulin. Specialty devices are available that can be preset to draw up the correct amounts of insulin. Family members may have to assist the patient.
- Teach the patient the importance of yearly comprehensive eye examinations to detect visual changes for treatment.

**EVALUATION.** Patient goals are met if the patient is able to manage the therapeutic regimen.

**Retinal Detachment**

**Pathophysiology and Etiology**

Retinal detachment is a separation of the retina from the choroid layer beneath it (see Fig. 51.1), allowing fluid to enter the space between the layers. The three causes of retinal detachment are: a hole or tear in the retina that allows fluid to flow between the two layers, fibrous tissue in the vitreous humor that contracts and pulls the retina away from its normal position, or fluid e xudate accumulation in the subretinal space that separates the retinal layers.

**Signs and Symptoms**

Patients experiencing a retinal detachment report a sudden change in vision. Initially, as the retina is pulled, patients report seeing flashing lights and then **floaters.** The flashing lights are caused by vitreous traction on the retina, and floaters are caused by hemorrhage of vitreous fluid or blood. When the retina detaches, patients commonly describe it as “looking through a veil” or “cobwebs” and finally “like a curtain being lowered over the field of vision,” with darkness resulting. There is no pain because the retina does not contain sensory nerves. On visual examination, the patient typically has a loss of peripheral vision when the visual fields are tested and a loss of acuity in the affected eye.

**Diagnostic Tests**

Indirect ophthalmoscopy allows the examiner to visualize the retina, which may be pale, opaque, and in folds with retinal detachment to diagnose the type of detachment. If there are lesions in the eye, the slit-lamp examination allows the examiner to magnify the lesions.

**Therapeutic Measures**

Immediate medical treatment must be sought to help protect vision. The degree of vision restoration varies and depends on the affected area. One or more procedures may be performed to treat retinal tears, or detachment: laser surgery, cryopexy, scleral buckling, and pneumatic retinopexy.

**LASER SURGERY.** Laser surgery focuses a laser beam at the torn area of the retina, causing a controlled burn, which scars around the tear and reattaches the retina to surrounding tissue.
CRYOPEXY. Cryopexy is the placement of a supercooled probe on the sclera over the affected area. The probe freezes and scars the tear or hole, a principle similar to the laser procedure.

SCLERAL BUCKLING. Scleral buckling is a surgical procedure for retinal detachment that involves placing a silicon implant in conjunction with a beltlike device around the sclera to bring the choroid in contact with the retina. Cryosurgery or laser surgery is used before the buckling procedure to seal the tear and form a scar that helps adhere the retina and choroid layers together. Vitrectomy is often done as well.

PNEUMATIC RETINOPEXY. Pneumatic retinopexy, done for retinal detachment, is a procedure that can be conducted in the health care provider’s office but is time-consuming for the patient. This procedure involves injecting air or gas into the chamber to hold the retina in place. The patient must be extremely compliant with the treatment regimen, reclining for about 16 hours before the procedure to allow the retina to fall back toward the choroid. Because air rises, the patient must maintain a position that keeps the air bubble against the detached area for up to 8 hours a day for 3 weeks.

Complications
With any of the retinal procedures there is risk of increased intraocular pressure (IOP), tears and recurrent detachment.

Nursing Process for the Patient With Retinal Detachment

DATA COLLECTION. Subjective data collected include patient observation of the loss of peripheral vision, any change in visual acuity, and the presence of floaters, flashing lights, cobwebs, or veil-like visual impairments. There should be an absence of pain. Objective data collected include the patient’s visual acuity, visual fields, ability to perform ADLs, and level of anxiety.

NURSING DIAGNOSES, PLANNING, IMPLEMENTATION, AND EVALUATION. The nursing process for patients with retinal detachment can be found in the “Nursing Process for the Patient Having Eye Surgery” section later in this chapter.

CRITICAL THINKING

Mr. Samuel

Mr. Samuel, age 65, is working in the yard when a branch strikes his right eye. He sees flashes of light and then a short time later a dark shadow out of the right eye.

1. What should Mr. Samuel do?
2. After having a scleral buckling procedure, Mr. Samuel reports nausea. What action should the nurse take?
3. Ondansetron (Zofran) 4 mg intramuscular (IM) now is ordered. Available is ondansetron 2 mg/mL in 2 mL/vial. How many milliliters should be given?

Suggested answers are at the end of the chapter.

Glaucoma

Glaucoma is a group of diseases characterized by damage to the optic nerve, the structure responsible for transmitting visual information from the eye to the brain. The damage is silent, progressive, and irreversible until the end stages, when loss of peripheral vision occurs, followed by reductions in central vision and eventually blindness (see Fig. 52.2). Sometimes there is abnormal pressure within the eye that damages the optic nerve, but not always. Normal tension glaucoma is now known to exist. There is no cure for glaucoma, so treatment plans must be followed to prevent further vision loss.

Pathophysiology

The most common form of glaucoma, called primary, consists of two types: primary open-angle glaucoma (POAG) and acute angle-closure glaucoma (AACG). Secondary glaucoma may be caused by infections, tumors, or injuries. A third form, congenital glaucoma, is due primarily to developmental abnormalities.

AACG occurs in people who have an anatomically narrowed angle at the junction where the iris meets the cornea. When nearby eye structures such as the iris protrude into the anterior chamber, the angle is occluded, which blocks the flow of aqueous fluid. This is considered a medical emergency and results in partial or total blindness if not treated. POAG occurs when the drainage system of the eye, the trabecular meshwork and Schlemm’s canal, degenerate and subsequently block the flow of aqueous humor.

Etiology and Prevention

The incidence of AACG is highest among Asians, women older than age 45, and people who are nearsighted. POAG incidence increases in those older than age 40 (over age 50 for European Americans, over age 35 for African Americans), in people with diabetes, and in those with a family history of glaucoma, and is four to five times more prevalent in African Americans than European Americans. Those over age 60 or in high-risk groups should have yearly eye examinations for glaucoma detection.

Signs and Symptoms

An ophthalmic emergency, AACG typically has a unilateral, rapid onset. The patient may report severe pain over the affected eye, blurred vision, rainbows around lights, and photophobia and have eye redness, a steamy-appearing cornea, and tearing. Increased IOP can cause nausea and vomiting.

POAG develops bilaterally. The onset is usually gradual and painless, so the patient may have no noticeable symptoms or, after time, may experience mild aching in the eye, headache, halos around lights, or frequent visual changes that are not corrected with eyeglasses.

Diagnostic Tests

Measuring IOP and identifying optic nerve damage and visual loss are done to diagnose glaucoma. Tonometry detects increased IOP (normal: 12–20 mm Hg), which may be present in about 50% of glaucoma cases. In AACG, IOP
may exceed 50 mm Hg. The GDx Access, a laser device, detects nerve damage long before the patient has symptoms of glaucoma. Additionally, a visual field examination looks for loss of peripheral vision, distance vision is assessed, and corneal thickness is measured. With gonioscopy, a special lens is used to determine if glaucoma is open-angle or angle-closure.

**Therapeutic Measures**

The first-line treatment for glaucoma focuses on opening the aqueous flow by administering cholinergic agents (**miotics**), such as carbachol (Isopto) or pilocarpine (Pilocar) to constrict the pupil. When the pupil is constricted, the iris pulls away from the drainage canal so the aqueous fluid can flow freely. A second medication may be given to slow the production of aqueous fluid that includes carboxic anhydrase inhibitors such as acetazolamide (Diamox), adrenergic agonists such as dipivefrin (Propine), and beta blockers such as timolol (Timoptic). Slowing the production of aqueous fluid helps decrease IOP. Additionally, steroid eyedrops may be ordered to reduce inflammation. The patient experiencing an acute attack of AACG is given these types of medications and mannitol, a hyperosmolar agent, to rapidly reduce IOP, as well as analgesics, and is on complete bed rest.

Patients with glaucoma need lifelong use of eye drop medications twice or more daily. In the absence of symptoms, adherence to treatment is often an issue. Other factors that contribute to nonadherence to treatment include the patient’s age, inability to afford the medication, and lack of understanding of the disease process. Patients should carry medical alert identification for their glaucoma and medications. This can help prevent administration of medications in emergency situations that are contraindicated for glaucoma.

There are medications, regardless of their route, that are contraindicated in AACG that can result in blindness if given to a patient with AACG. These medications include anticholinergics such as atropine, antihistamines such as diphenhydramine (Benadryl), or hydroxyzine (Vistaril) because they are mydriatics. Before a medication is given, the nurse should determine that it is not contraindicated in AACG, to prevent blindness from occurring.

**Surgical Management**

When medication is no longer able to control the flow of aqueous humor or reduce the IOP, surgical intervention may become necessary. Surgery focuses on creating an area where the aqueous humor can flow freely, thus preventing increased IOP (Fig. 52.3). For AACG, laser peripheral iridotomy or surgical iridectomy is performed. Laser iridotomy is a noninvasive procedure using a laser to remove a portion of the iris, thus allowing aqueous fluid to flow through the area. Prophylactic iridotomy may be performed on the other eye to prevent AACG. POAG is treated with laser trabeculoplasty (noninvasive laser beam creates openings in trabecular meshwork), trabeculectomy (part of iris and trabecular meshwork removed), or cyclocryotherapy (cryoprobe destroys part of ciliary body).

**LEARNING TIP**

- Mydriatic medications are contraindicated in acute angle-closure glaucoma because they can cause an acute episode of increased IOP by dilating the pupil and pushing the iris back, blocking the outflow of aqueous humor.
- Miotic medications constrict the pupil and so may be given to patients with acute angle-closure glaucoma.
- To remember what miotic medications and mydriatic medications do, so that the appropriate medication is given and contraindicated ones are never given, remember the following:

  \[ D = \text{dilate = mydriatic = do not give.} \]
  \[ \text{No } D = \text{constricts = miotic = okay to give.} \]

**Nursing Process for the Patient With Glaucoma**

**DATA COLLECTION.** The patient should be monitored for pain, loss of central and peripheral vision, understanding of disease and adherence to treatment regimen, and ability to conduct ADLs.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.** The goal of nursing care for the patient with glaucoma is to prevent further visual loss and to promote comfort if the patient is experiencing pain with acute glaucoma. See the “Nursing Process for the Patient With Visual Impairment and Nursing Process for the Patient Having Eye Surgery” sections for additional nursing diagnoses.

- **Pain related to increased intraocular pressure**
  - **EXPECTED OUTCOME** The patient will report that pain is relieved.
  - Give analgesics as needed for acute glaucoma to relieve pain.

**FIGURE 52.3 Flow of aqueous humor after trabeculoplasty (arrows).**
Self-Care Deficit related to decreased vision

**EXPECTED OUTCOME:** The patient will be able to care for self with assistance if needed.

- Assist with self-care as needed to ensure ADLs are met.

Anxiety related to partial or total visual loss

**EXPECTED OUTCOME:** The patient will state that anxiety is reduced.

- Encourage patient to verbalize concerns about glaucoma to allow questions to be answered.

Risk for Injury related to decreased vision

**EXPECTED OUTCOME:** The patient will not suffer injury as a result of the visual impairment.

- Refer patient to support services that provide adaptive visual devices.
- Teach patient and family not to rearrange furniture without patient knowledge to prevent falls or injury.

Deficient Knowledge related to medical regimen, disease process due to no prior experience

**EXPECTED OUTCOME:** The patient will demonstrate correct instillation of eye medications and be able to verbalize understanding of condition and treatment.

- Teach need for regular eye examinations through dilated pupils to monitor disease and detect complications.
- Teach how to administer medications with a return demonstration to ensure that eye drops are administered properly.
- Teach the patient to rest his or her hand on the forehead if the patient has trouble keeping the hand steady when administering eye drops.
- Consider large-print labels or audiotaped directions if the patient is unable to see the label on the eye drop bottle.
- Consider placing large, multicolored dot stickers on medication bottles and on corresponding instruction cards for patients with multiple medications.
- Advise family members that they are at increased risk of developing glaucoma and should have regular eye examinations because glaucoma can be hereditary.

**EVALUATION.** Interventions are successful if the patient maintains an acceptable level of comfort, has no further loss of vision, is able to care for self with assistance, expresses concerns and anxieties, does not suffer injury as a result of the visual impairment, demonstrates correct instillation of eye medications, and is able to verbalize understanding of condition and treatment.

**Cataracts**

**Pathophysiology and Etiology**

A cataract is an opacity in the lens of the eye that may cause a loss of visual acuity (see Fig. 52.2). Vision is diminished because the light rays are unable to get to the retina through the clouded lens.

Factors that contribute to cataract development may include age, ultraviolet radiation (sunlight), diabetes, smoking, steroids, nutritional deficiencies, alcohol consumption, intraocular infections, trauma, and congenital defects.

**Signs and Symptoms**

Cataracts are painless. Symptoms of cataract formation may include halos around lights, difficulty reading fine print or seeing in bright light, increased sensitivity to glare such as when driving at night, double or hazy vision, and decreased color vision.

**Diagnostic Tests**

Cataracts are diagnosed with an eye examination. Visual acuity is tested for near and far vision. The direct ophthalmoscope and slit-lamp microscope are used to examine the lens and other internal structures.

**Surgical Management**

When cataracts begin to interfere with daily living and quality of life, treatment is recommended. One eye is treated at a time with outpatient surgical removal of the cloudy lens. Implantable lenses, which come in various types, are typically inserted after lens removal. Eyeglasses or contact lenses are needed if no lens is reinserted. Eyeglasses may also be needed with some of the lens implants. With the no-stitch cataract operation, there are no postoperative activity restrictions, and vision improves in about 1 to 2 days.

**Complications**

Complications of cataract surgery are rare but include inflammation, increased IOP, macular edema, retinal detachment, vitreous loss, hyphema, endophthalmitis, and expulsive hemorrhage.

**Nursing Process for the Patient With Cataracts**

**DATA COLLECTION.** The patient is monitored for visual deficits to assist care planning, as well as knowledge needs about the disease process, surgical intervention, postoperative care, and medical regimen. The majority of patients undergoing cataract surgery have same-day surgery and then go home. So the home situation, the ability of the patient or family member to follow the medical regimen, and transportation to and from the hospital for the patient are evaluated.

**NURSING DIAGNOSES, PLANNING, IMPLEMENTATION, AND EVALUATION.** Preoperative and postoperative nursing care is the primary nursing responsibility for the patient with cataracts, as discussed next.

**Nursing Process for the Patient Having Eye Surgery**

**DATA COLLECTION.** Table 52.5 reviews subjective data to be collected. Objective data may include visual acuity and peripheral field measurements. Visual acuity should be tested with and without any corrective lenses. Eye tearing, redness, or swelling is noted.
Risk for Injury related to altered visual acuity

**EXPECTED OUTCOME:** The patient will remain free of injury.

- Explain that depth perception may be affected by eye surgery, which can result in falls, to help prevent injury.
- Ambulate with assistance and use clearly marked stairs to prevent injury.
- At home, beverages can be poured and stored in the refrigerator in single-serving glasses to prevent spills and slippery floors.

Deficient Knowledge related to preoperative and postoperative eye care

**EXPECTED OUTCOME:** The patient will verbalize preoperative and postoperative care directions.

- Teach disease process, surgical intervention, use of correct technique for administering eye medications, need to report for medical follow-up as instructed, and need to protect the eye from further injury to increase patient knowledge.
- Patients are told to seek medical treatment if they experience sudden, worsening pain, an increase in watery or bloody discharge, or sudden loss of vision because these are signs of hemorrhage or problems.

Anxiety related to visual alteration and surgery

**EXPECTED OUTCOME:** The patient will report reduced anxiety.

- Give patients the opportunity to discuss their feelings about vision loss and surgery to reduce anxiety.

**EVALUATION.** The patient goals have been met if the patient is free of injury, verbalizes preoperative and postoperative directions, and reports reduced anxiety.

---

**Macular Degeneration**

**Pathophysiology and Etiology**

Age-related macular degeneration (AMD) is the leading cause of visual impairment in U.S. residents older than age 50. It involves deterioration and scarring within the macula, the area on the retina where light rays converge for the sharp, central vision needed for reading and seeing small objects. The macula is also responsible for color vision (Fig. 52.4). There are two types of AMD: dry (atrophic) and wet (exudative). In dry AMD, photoreceptors in the macula fail to function and are not replaced because of advancing age. This accounts for 70% to 90% of cases. In the wet form, retinal tissue degenerates, allowing vitreous fluid or blood into the subretinal space. New fragile blood vessels form (angiogenesis) and compromise the macular tissue, causing subretinal edema. Eventually, fibrous scar tissue forms, severely limiting central vision.

People at risk of developing macular degeneration include those older than age 60, those with a family history of macular degeneration, persons with diabetes, people who smoke, those frequently exposed to ultraviolet (UV) light, and Caucasian people.

---

**NURSING CARE TIP**

Most damaging exposure to UV light occurs before age 18. So it is important for everyone of all ages to use adequate UV protective eyewear.
Prevention
A healthful lifestyle and a diet that includes dark green leafy vegetables (kale, collard greens, lettuce, spinach), and orange (peppers) and yellow (corn) color fruits and vegetables is important. Measuring macula pigment optical density is an important preventative tool. Taking the retinal carotenoids lutein and zeaxanthin and zinc supplementation for a low macula pigment optical density (less than 44) can be beneficial in raising the macula pigment optical density over time and preventing progression of some macular degeneration.

Signs and Symptoms
AMD of the dry type is characterized by slow, progressive loss of central and near vision (see Fig. 52.2). Although people usually have the condition in both eyes, each eye may be affected in varying degrees. AMD of the wet type has the same loss of central and near vision, but the onset is sudden and results in more severe vision loss. The loss can occur in one or both eyes. This vision loss is described as blurred vision, distortion of straight lines, and a dark or empty spot in the central area of vision. Some patients may have a decreased ability to distinguish colors.

Diagnostic Tests
Examination of the patient begins with visual acuity for near and far vision and an examination of the internal eye structures with an ophthalmoscope. The examiner uses an Amsler grid (Fig. 52.5) to detect central vision distortion and a color vision test to evaluate color differentiation. Patients are given an Amsler grid to look at on a regular basis to monitor vision changes. If any of the grid lines look crooked or disappear, the patient should contact the HCP. Digital imaging, optical coherence tomography retinal scan (similar to a computed tomography scan) or intravenous fluorescein (dye) angiography can also be used to evaluate blood vessel leakage or abnormalities in the eye.

Therapeutic Measures
Unfortunately, there is no treatment for the dry type of AMD, so prevention is important when possible. Most patients with dry AMD do not lose peripheral vision or become totally blind, but most are classified as legally blind (less than 20/200 vision with correction). Low-vision telescopic glasses can enhance remaining vision. A telescope implant for those
Chapter 52  Nursing Care of Patients With Sensory Nervous System Disorders: Vision and Hearing

with advanced AMD, done in one eye after the lens in the eye is removed, can help restore central vision. Visit www.CentraSight.com for more information.

The newer evidence-based treatment option for wet type AMD is intermittent injection into the eye of an antiangiogenesis medication (e.g., ranibizumab [Lucentis]). Drugs that are antiangiogenic prevent the formation of new fragile blood vessels that can become leaky and bleed. Treatment options that are not used as much as in the past due to the availability of antiangiogenesis drugs include laser photoagulation that seals the leaking blood vessels or photodynamic therapy. If the patient receives laser photoagulation, there is a small, permanent blind spot at the point of laser contact with the macula. Clinical trials are ongoing with a ye drop to treat wet AMD (Squalamine Lactate Ophthalmic Formulation 0.2%) that prevents angiogenesis. Another treatment in development is the VEGF Trap Eye, a biologically produced protein that will also prevent angiogenesis. With either type of AMD, patients have significant visual loss and must adapt to it.

Nursing Process for the Patient With Macular Degeneration

See the “Nursing Process for the Patient With Visual Impairment” section.

Trauma

Emergencies and trauma of the eye must be assessed immediately so that proper treatment can be initiated. Injuries to the eye include foreign bodies, chemical burns, ultraviolet, or direct heat sources, abrasions, lacerations from dragging something across the eye, and penetrating wounds, which are the most serious eye injury and increase the risk for infection and blindness.

Signs and Symptoms

Foreign bodies produce pain when the eyeball or eyelid moves. Usually the eye tears excessively in an attempt to irrigate the noxious substance out of the eye. Injuries that irritate or penetrate layers of the cornea range from mild to severe pain. With corneal abrasions, the pain sensation may be delayed for several hours. Other symptoms that may be seen with abrasions, lacerations, and foreign bodies include conjunctival redness, photosensitivity, decreased visual acuity, erythema, and pruritus. Acute pain and burning are characteristic symptoms of a burn to the eye. Penetrating wound symptoms depend on the area of the eye involved and the extent of the damage.

Diagnostic Tests

Visual acuity is tested. It is important to establish baseline acuity to evaluate effectiveness of treatment, although many patients resist acuity testing because of the discomfort. Testing includes examination by slit-lamp microscope and direct ophthalmoscope. Fluorescein staining is used to evaluate abrasions.

Therapeutic Measures

Foreign bodies are treated with a normal saline flush to irrigate the object out of the eye or to a point where it can be removed with a swab. Topical antibiotic ointment is prescribed to prevent infection. Chemical burns must be treated immediately with a 15- to 20-minute irrigation of either tap water at the work site or sterile solution at the medical facility. Topical antibiotic ointments are usually prescribed. Burns from heat or UV radiation are not irrigated.

Abrasions and lacerations usually are treated with anti-infective ointments or drops after cleansing the eye with normal saline.

An eye specialist treats penetrating wounds. Upon initial injury, both eyes should be covered to prevent ocular movement. If there is a protruding object, it should be stabilized but not removed until the HCP can assess the patient.

Complications

If the eye cannot be saved with medical treatment, it may be necessary to surgically remove the eye. This procedure is called enucleation (entire eyeball removal).

Nursing Process for the Patient With Eye Trauma

DATA COLLECTION AND EMERGENCY INTERVENTION.

Foreign Bodies. The eye is inspected for foreign bodies, which may be visible on the eyeball. The lids should be everted to examine the surface. Then the eye is irrigated.

Burns. Assessment of the type of burn is done because treatment options vary. Immediate irrigation of the eye is performed once it has been established that a chemical burn has taken place unless contraindicated for the chemical. Medication and eye patching are applied as indicated.

Abrasions and Lacerations. The eye is assessed for visible lacerations and then cleansed, medicated, and patched as indicated.

Penetrating Wounds. The patient is kept calm and relaxed to minimize eye movement and increased IOP. If a protruding object is present, the object is stabilized with tape or other supports.

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.

Acute Pain related to inflammatory process and injury

EXPECTED OUTCOME: The patient's pain level will be within an acceptable range for the patient.

• Administer analgesics as ordered to reduce pain.

• Assist patient in remaining calm and relaxed to reduce pain.

Risk for Infection related to eye trauma

EXPECTED OUTCOME: The patient will remain free of infection.

• Use sterile technique when irrigating the eye, when applying medications, and during examination to prevent infection.

Anxiety related to visual-sensory deficit

EXPECTED OUTCOME: The patient will verbalize a reduction in anxiety.

• Encourage the patient to verbalize feelings about visual impairment to reduce anxiety.

• Reassure patient as appropriate to reduce anxiety.

• Word • Building •

enucleation: e—removed from + nuclear—center
Deficient Knowledge related to medical regimen due to lack of previous experience

EXPECTED OUTCOME: The patient will be able to verbalize care of the eye.

• Teach patient about interventions and follow-up care to inform patient.

EVALUATION. Patient goals have been met if pain level is within an acceptable range for the patient, patient remains free of infection, patient is able to verbalize a reduction in anxiety, and patient is able to verbalize care of the eye.

HEARING DISORDERS

Hearing Loss

Hearing loss is the most common disability in the United States and can be acquired or congenital. Hearing impairment ranges from difficulty understanding words or hearing certain sounds to total deafness (Table 52.6). Hearing impairment can affect communication, social activities, and work activities and can diminish quality of life. Nurses have a responsibility to communicate with patients with hearing impairments and provide needed information regarding health care.

Conductive Hearing Loss

Conductive hearing loss, a mechanical problem, is interference with the conduction of sound impulses through the external auditory canal, the eardrum, or the middle ear to the inner ear. The inner ear is not involved in a pure conductive hearing loss. Causes of conductive hearing loss include cerumen, foreign bodies, infection, perforation of the tympanic membrane, trauma, fluid in the middle ear, cysts, tumor, and otosclerosis. Many causes of conductive hearing loss, such as infection, foreign bodies, and impacted cerumen, can be corrected. Hearing devices may improve hearing for conditions resulting in conductive hearing loss that cannot be corrected, such as scarring tympanic membrane or otosclerosis.

Sensorineural Hearing Loss

Sensory hearing loss originates in the cochlea and involves the hair cells and nerve endings. Neural hearing loss originates in the nerve or brainstem. Sensorineural hearing loss results from disease or trauma to the sensory or neural components of the inner ear. Some of the causes of nerve deafness are complications of infections (such as measles, mumps, meningitis).

and meningitis), ototoxic drugs (Table 52.7), trauma, noise, neumera, arteriosclerosis, and the aging process.

**Presbycusis** is hearing loss caused by the aging process that results from degeneration of the organ of Corti. This degenerative process often begins in the fifth decade of life. The individual develops an inability to decipher high-frequency sounds (consonants s, z, t, f, and g). This interferes with the person’s ability to understand what is being said, especially in noisy environments. The older adult commonly has more difficulty understanding higher pitched female voices than lower pitched male voices.

**Other Types of Hearing Loss**

Mixed hearing loss occurs when an individual has both conductive and sensorineural hearing loss. This can be caused by a combination of any of the disorders previously mentioned. Central hearing loss occurs when the central nervous system cannot interpret normal auditory signals.

**Therapeutic Measures**

The goal of medical management is to improve the patient’s hearing. With any permanent hearing loss, the use of a hearing aid should be considered (Chapter 51, Fig. 52.6). Surgical intervention may be available for patients whose hearing is not improved with hearing aids. Implantable middle ear hearing aids can improve sound perception for patients with moderate-to-severe sensorineural hearing loss. Cochlear implants can restore up to half of the patient’s hearing (Chapter 51).

**Nursing Process for the Patient With Hearing Impairment**

**DATA COLLECTION.** Nursing care includes identifying those patients at risk for hearing impairment (Table 52.8). Patients with renal or hepatic disease, using two or more ototoxic drugs, or previously having used ototoxic drugs are at risk for developing hearing impairment. If your patient is taking ototoxic medications, assess for tinnitus, sensorineural hearing loss, or vestibular dysfunction, which could indicate ototoxicity. The medications should be discontinued if signs of ototoxicity are present. Monitor for signs of vertigo, horizontal nystagmus, nausea, vomiting, and spinning or rocking sensation while sitting still. To collect data for the patient with hearing impairment, ask family members, as well as the patient, questions related to the patient’s hearing status.

Objective data collection should start with normal conversation with the patient. Observe the patient for difficulty understanding conversation or questions. Clarity of the patient’s speech is also determined. Physical examination includes the whisper voice, Rinne, and Weber tests (see Chapter 51). Test results provide an estimate of conductive or sensorineural hearing loss. The patient should be assessed for the underlying cause of the problem to determine if it is external, middle,
or inner ear problem. Examination of the external ear may reveal an external ear problem. The HCP may examine the ear canal for impacted cerumen or a tympanic membrane problem. Any assistive hearing devices should be noted and inspected for proper functioning. The results of the examination are documented and communicated to other health team members (see “Evidence-Based Practice” box).

| Are both ears affected? Is one side worse than the other? |
| Are certain words unclear, or entire conversations? Are high-frequency sounds (consonants s, t, z, f, g, and female voices) unclear or difficult to understand? Is any pain associated with the hearing loss? Any tinnitus or vertigo? |
| Is hearing worse in large groups or when there is a lot of background noise? Is hearing improved in a quiet environment or when speaking only to an individual? Is it easier to understand someone when seeing the person’s lips move? Does the patient own or use any assistive hearing devices? Are they effective? What type is used? |
| When did the hearing loss start? Was it gradual or sudden? Is the hearing loss associated with any illness or traumatic event? Is it associated with any recent flying? Any history of ototoxic drug use? |
| Does it cause communication impairment? How much? Does it affect activities of daily living? Does it affect or limit usual social activities? Have family or friends commented on decreased hearing? Does patient avoid communication or social activities because of difficulty hearing? Is patient having difficulties hearing telephone voices, radio, television, or movies? |
| Is there any fever, nausea, vomiting, or dizziness? Is there any history of occupational or environmental exposure to loud noises? What are the usual ear self-care habits? Any history of impacted cerumen? Has patient ever had cerumen removed from ears? |
| What does the patient feel is wrong? Does the patient think that he or she has a hearing problem? How does the patient feel about hearing assistive devices? How does the patient perceive the hearing loss, and how is it influencing the patient’s life? |

Results demonstrated that hearing loss was independently associated with hospitalization and poorer self-reported health over the past 12 months.

**Implications for Nursing Practice**

Additional research is needed to investigate whether hearing rehabilitative therapies could help reduce hospitalizations and improve self-reported health in older adults with hearing loss. Nurses can implement interventions to ensure that older adults optimize their ability to hear. Improved hearing positively affects communication and other areas of self-reported health and might possibly decrease hospitalizations.

**REFERENCE**

**Nursing Diagnoses, Planning, and Implementation.**
Planning focuses on helping the patient optimize hearing, promoting communication, and promoting adjustment to impaired hearing (Box 52-2 and Box 52-3). Nursing management for the patient with hearing impairment focuses on enhancing communication and quality of life (see the “Nursing Care Plan for the Patient With Hearing Impairment”). Families should be included in discussions about therapeutic hearing devices and their care, enhancing communication, and limiting isolation.

**Evaluation.** The patient’s goals are met if the patient communicates effectively, engages in usual social activities, uses assistive hearing device, copes with emotional reaction to hearing impairment, and demonstrates care of hearing aid.

**Box 52-2 Communicating with a Person Who Has a Hearing Impairment**
- Get the person’s attention before beginning to speak.
- Face and stand close to the person being spoken to and maintain eye contact.
- Avoid standing in the glare of bright sunlight or other bright lights.
- Speak clearly, at a normal rate and volume. Do not shout or overarticulate.
- Inform the listener of topics to be discussed and when a change of topic occurs. Stick to a topic for a while and avoid quick shifts.
- Use short sentences and assess for understanding. If the listener does not understand after the message is repeated, rephrase the message. If the listener has difficulty with high-pitched sounds, lower the voice pitch.
- Allow extra time for the listener to respond and do not rush the listener.
- Ensure an optimum environment by reducing background noises: turn off television and radio, close the door, or move to a quieter area.
- Encourage nonverbal communication such as touch or gestures as appropriate.
- If the listener uses a hearing device, ensure that it is operational and in place before beginning to communicate. Give the person time to adjust the hearing device before speaking.
- Do not smile, chew gum, or cover the mouth when talking.
- Use active listening with attentive body posture, pleasant facial expressions, and a calm, unhurried manner.
- Do not avoid conversation with a person who has hearing loss.
- Use written communication if unable to communicate verbally.

**Box 52-3 Care of Hearing Aids**
- Insert hearing aid while over a soft surface such as a pillow to prevent damage if the hearing aid is dropped during insertion.
- Remove hearing aid before showering or bathing. Do not immerse in water.
- Turn the hearing aid off when not in use to conserve battery.
- Do not expose the hearing aid to extreme heat or cold.
- Clean the hearing aid daily with a dry, soft cloth. Clean earmold with small brush or toothpick to keep free of earwax.
- Turn off the hearing aid and turn the volume down before inserting. Turn hearing aid on and increase volume once it is inserted.
- Minimize whistling noise by ensuring that the volume is not too high, the aid fits securely, and the aid is free from earwax.
- Check battery or lower the volume if sound is not clear or is intermittent. Buzzing noise may indicate that the battery door is not completely closed.
- Do not expose the hearing aid to hair or medicinal sprays by applying sprays before inserting hearing aid.

**External Ear Infections**

**Pathophysiology and Etiology.** Infection is the most common disorder of the external ear, with external otitis being the most common infection. Exposure to moisture, contamination, or local trauma provides an ideal environment for pathological growth in the external ear, which results in external otitis. It may be caused by bacterial or fungal pathogens. Staphylococci are the most common causative organism. Pneumocystis infections have been seen in patients who have human immunodeficiency virus (HIV). A bacterial or fungal external otitis that occurs when water is left in the ear and washes away protective earwax, often after water exposure or trauma, is known as swimmer’s ear. External otitis occurs more often in the summer months but can be seen year-round in patients who swim indoors.

A localized infection called ear canal furuncle or abscess results when a hair follicle becomes infected. A carbuncle forms when several hair follicles are involved in forming the abscess. Most furuncles and carb uncles erupt and drain spontaneously. Otomycosis is an infection caused by fungal growth and is typically seen after topical corticosteroid or antibiotic use. Otomycosis occurs more often in hot weather. An infection of the auricle is called perichondritis, which can result in necrosis of cartilage.
NURSING CARE PLAN for the Patient With Hearing Impairment

Nursing Diagnosis: Impaired Verbal Communication related to impaired hearing

Expected Outcome: Patient will use effective communication techniques.

Evaluation of Outcome: Patient is able to communicate effectively to have needs met and reduce social isolation.

Intervention
- Begin assessment of hearing by inspecting ear canals for mechanical obstruction. If cerumen is found, use of a softening product is recommended to assist in wax removal. If canal is clear, continue assessment by using a tuning fork, loud ticking clock, or verbal cues to determine auditory ability at various distances. Rationale: Hearing loss may result from buildup of cerumen in the auditory canal. Determination of hearing ability assists nurse in developing interventions appropriate to patient’s hearing level. Evaluation: Is ear canal free of mechanical obstruction? Is patient able to hear verbal input? If not, how severe is the impairment?

Intervention
- Enhance hearing by giving auditory cues in quiet surroundings. Rationale: The presence of background noise such as television, radio, or large numbers of people makes hearing more difficult. Evaluation: Are auditory cues being delivered in an environment free of extraneous background noises?

Intervention
- Enhance understanding of auditory cues in well lit area but not in front of window causing glare by getting patient’s attention before speaking, speaking slowly with careful enunciation of words, adding hand gestures, speaking face to face with the person with the impairment, and adjusting the voice pitch downward without increasing volume. Rationale: Hearing is enhanced when additional cues assist the person in understanding the message. Use of hand gestures to point, lip-reading, facial expression, and lower pitch all assist communication. Evaluation: Are auditory cues being understood by patient? Are instructions given in step-by-step format with written cues?

Intervention
- Structure environment to compensate for hearing loss by adding visual indicators to telephone ringer, doorbell, smoke detectors, and other emergency sounds. Rationale: Assists in communication and safety. Evaluation: Is patient able to receive input in ways other than auditory?

Intervention
- Provide for optimal care of assistive appliances such as hearing aids by making sure that cerumen has been cleaned from the device, that batteries are charged, and that the appliance is placed correctly in ear. Rationale: Appliances that are not functioning properly will not assist patient in hearing. Evaluation: Is patient’s hearing aid in place correctly? Is cerumen blocking sound conduction? Do batteries work?

Intervention
- Introduce assistive devices such as hearing amplifiers, telephone amplifiers, telephones with extra-loud bells, written communication, and sign language. Rationale: Patients may not be aware of assistive devices that could help them adapt to hearing loss and continue previous activities, such as talking on the telephone or listening to television. Evaluation: Is patient aware of assistive devices that will allow him or her to continue to verbally communicate with others? Is patient able to use the devices to compensate for auditory impairment?

Intervention
- Refer to specialized clinician such as an audiologist or occupational therapist or to specialized resources such as the National Association of the Deaf or American Speech, Language and Hearing Association. Rationale: Specialized clinicians can provide detailed examination and treatment. Specialized resource groups have networks in place to help people cope with loss and maximize abilities. Evaluation: Does patient know whom to call for detailed examination and treatment? Does patient know that there are specialized clinicians and resource groups to help with hearing impairment? Does patient know how to access these specialists?
**Chapter 52  Nursing Care of Patients With Sensory Nervous System Disorders: Vision and Hearing**

**SIGNS AND SYMPTOMS.** The most common sign of infection of the external ear is pain (Table 52.9). An early indication of infection is pain with gentle pulling on the pinna. The patient may also experience pain when moving the jaw or when the otoscope is inserted into the ear canal. Pruritus (itching) is also a common symptom and can be an early sign of infection. Signs of inflammation are present on the external ear. The ear canal may become swollen or occluded, and as a result hearing may be diminished. Redness, swelling, and drainage can be observed during otoscopic examination. If drainage is present, it usually starts out clear and becomes purulent as the disease progresses. The patient may also be febrile.

**DIAGNOSTIC TESTS.** A complete blood cell count (CBC), with elevated white blood cell (WBC) counts, and cultures of discharge help diagnose infections. Culture and sensitivity tests isolate the specific infective organism and determine which antibiotics would be most effective to treat the infection. The Rinne and Weber tests can indicate conductive hearing impairment.

**Impacted Cerumen**

**PATHOPHYSIOLOGY AND ETIOLOGY.** Normally, the ear is self-cleaning. However, cerumen (wax) may become impacted, blocking the ear canal. People with large amounts of hair in the ear canal or who work in dusty or dirty areas are prone to cerumen impaction. Improper cleaning can also result in cerumen impaction. The older adult is at risk to develop impacted cerumen. This occurs because the amount of cerumen secreted is decreased and because of increased amounts of keratin. These two factors cause the cerumen to be drier, harder, and more easily impacted. Patients with hearing aids tend to have problems with impacted cerumen. Patients with bone growths secondary to an osteophyte or osteoma are at risk for cerumen impaction.

**SIGNS AND SYMPTOMS.** The patient may experience hearing loss, a feeling of fullness, or blocked ear if cerumen has become impacted (see Table 52.6). Otoscopic examination reveals cerumen blocking the ear canal.

**DIAGNOSTIC TESTS.** Audiometric testing reveals conductive hearing loss in the affected ear. Hearing acuity can be decreased by 45 decibels because of impacted cerumen. Whisper voice, Rinne, and Weber tests also indicate conductive hearing loss.

**Masses**

**PATHOPHYSIOLOGY AND ETIOLOGY.** Benign masses of the external ear are usually cysts resulting from sebaceous glands. Other benign masses are lipomas, warts, keloids, and infectious polyps. Infectious polyps usually arise from the...

**TABLE 52.9  EXTERNAL EAR DISORDERS SUMMARY**

| Signs and Symptoms | Pain  
|--------------------|-------
|                    | Pruritus, swelling, redness  
|                    | Drainage  
|                    | Lacerations, contusion, hematomas, abrasion  
|                    | Erythema, blistering  
|                    | Hearing loss  
|                    | Foreign body  
| Diagnostic Tests and Findings | Complete blood count with elevated white blood cells with infections audiometric, Rinne, Weber, and whisper voice tests (indicate conductive hearing loss with impacted cerumen and trauma)  
| | Imaging studies to indicate extent of trauma  
| Therapeutic Measures | Cerumenolytics to remove earwax  
| | Anti-infectives and anti-inflammatory medications (to treat infection)  
| | Debridement, surgical repair, or application of protective covering with trauma to external ear  
| Complications | Spread of infection to other parts of the ear  
| | Disfigurement  
| | Loss of hearing  
| | Scarring  
| Priority Nursing Diagnoses | Acute Pain related to inflammation or trauma  
| | Risk for Injury related to self-cleaning of external ear  
| | Deficient Knowledge related to care of hearing aid due to lack of prior experience  

---
middle ear and enter the external ear through a hole in the tympanic membrane. Actinic keratosis is a precancerous lesion that can be found on the auricle and may be seen in older adults. Malignant tumors such as basal cell carcinoma on the pinna and squamous cell in the ear canal may develop and can spread.

**SIGNS AND SYMPTOMS.** Changes in the appearance of the skin can occur with benign or malignant masses. Usually, impaired conductive or sensorineural hearing loss occurs with masses. Pain is another symptom and is usually described as deep pain radiating inward on the affected side. Ear drainage may be present. As the condition progresses, facial paralysis may occur. Visualization of the mass may be observed during otoscopic examination.

**DIAGNOSTIC TESTS.** A biopsy may be obtained to determine if the mass is benign or malignant. Imaging studies are also used to diagnose tumors. Audiometric studies reveal any hearing impairment.

**Trauma**

**PATHOPHYSIOLOGY AND ETIOLOGY.** Injuries to the external ear are commonly caused by a blow to the head, automobile accidents, burns, foreign bodies lodged in the ear canal, or cold temperatures. Cotton ball pieces and insects are the most common foreign bodies found in adults.

**SIGNS AND SYMPTOMS.** Lacerations, contusions, hematomas, abrasions, erythema, and blistering are signs seen with thermal or physical trauma. Repeated trauma to the ear can cause swelling, also known as cauliflower ear. This is common among boxers, rugby players, martial artists, and wrestlers. Conductive hearing loss can occur if the ear canal is partially or totally blocked. Patients who have contusions or hematomas commonly report numbness, pain, and paresthesia of the auricle. Symptoms associated with foreign bodies may include decreased hearing, itching, pain, and infection. Care is taken during otoscopic examination not to push the foreign body further into the ear canal.

**DIAGNOSTIC TESTS.** Imaging studies may be needed to determine the extent of the trauma. Audiometric, whisper voice, Rinne, and Weber tests may demonstrate conductive hearing loss.

**Complications of External Ear Disorders**

If not treated, infections can spread, causing cellulitis, abscesses, middle ear infection, and septicemia. Metastasis can occur if malignant tumors are not treated. Infection, trauma, and malignant tumors may cause temporary or permanent hearing loss, disfigurement, discoloration, and scarring.

**Therapeutic Measures for External Ear Disorders**

For external ear infections topical antibiotics are given. Systemic antibiotics are used for severe infections that are localized or have spread to surrounding tissues. Analgesics are used to control pain. Topical or systemic steroids may be used to treat inflammation. The ear is thoroughly cleaned before starting any topical treatment. If the external ear canal has drainage or is swollen shut, a wick may be inserted. The wick serves to aid in removing drainage or to aid in administering medication into the ear canal. Cerumen may be removed with irrigation by a trained clinician (Fig. 52.7; see “Evidence-Based Practice”). Irrigation is not used if the patient has a history of perforated tympanic membrane (eardrum) or other contraindications. Débridement, surgical repair, or application of a protective covering may be done when trauma occurs to the external ear. Surgical management consists of incision and drainage of abscesses. Excision of cysts or cutaneous carcinomas may also be required.
Nursing Process for the Patient With External Ear Disorders

DATA COLLECTION. Subjective data obtained in a patient history include reports of pain, fullness, previous cerumen impaction, itching, or hearing loss, as well as onset, duration, and severity of symptoms. Additional data include patient’s occupation, previous ear problems, use of a hearing aid, and typical ear hygiene. Observation for objective data includes redness, swelling, drainage, furuncles, carbuncles, lesions, abrasions, lacerations, growths, cerumen, scaliness, or crusting. The patient may report pain when the ear is palpated. Basic hearing acuity tests are conducted to evaluate hearing loss (see Chapter 51).

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.
Possible nursing diagnoses include the following.

Acute Pain related to inflammation or trauma
**Expected Outcome:** The patient’s pain will be decreased or absent as evidenced by a lower rating on a pain scale.

- Assess for nonverbal signs of ear pain to identify pain.
- Identify with the patient an optimum analgesic schedule to promote comfort.
- Implement nonpharmacological methods, such as relaxation, massage, music, guided imagery, or distraction techniques to relieve pain.
- Apply heat as ordered to the area to promote comfort.
- Offer liquid or soft foods to relieve pain when chewing.

Risk for Injury related to self-cleaning of external ear
**Expected Outcome:** The patient will explain or demonstrate prescribed treatment.

- Explain ear care (Box 52-4) to prevent injury.
- Teach patient treatment regimen to ensure completion of treatment.

Deficient Knowledge related to lack of information on preventive ear care
**Expected Outcome:** The patient will explain or demonstrate procedures to maintain wellness of the external ear.

- Explain procedure before removal of cerumen to decrease anxiety.
- If a wick is inserted into the ear canal, explain to patient that it is used to monitor for drainage and report excessive drainage to HCP.
- Teach patient how to use topical antibiotics, oral antibiotics, and/or anti-inflammatory medications to promote healing.
- Teach the patient how to complete the prescribed treatment and maintain ear health (see Box 52-4). Include how to administer eardrops or ointments, keep the ear clean and dry, and use cotton with petroleum jelly or earplugs to avoid getting water in the ears during an infection.

Box 52-4 Ear Care

1. Cleanse the external ear with a wet washcloth. Gently cleanse the helix.
2. The ear has an effective self-cleaning system that continually moves protective earwax outward to prevent buildup. Cleaning attempts such as with swabs can impact the wax. Never insert anything into the ear canal, including, cotton-tipped applicators, hair pins, matchsticks, safety pins, toothpicks, paper clips, or fingers. The thin skin of the ear canal is very fragile and can become abraded and then infected from being touched with these objects.
3. A person with a history of ear infections, perforated tympanic membrane, or swimmer’s ear should prevent moisture from entering the ear canal and should avoid swimming in contaminated water. Moisture or water in the ear canal can be prevented by using special earplugs.
4. For frequent swimming use: an ear conditioner to prevent ear dryness, an ear dryer after swimming, swim earplugs (custom or over the counter).
5. Avoid home remedies for ear care without consulting a HCP.
6. A person with an upper respiratory infection should gently blow the nose with both nares open to prevent microbes from being forced up the eustachian tubes.
EVALUATION. The outcomes for the patient are met if patient indicates pain is decreased or absent as evidenced by a lower rating on a pain scale, hearing improves or returns to preillness level, states or demonstrates prescribed treatment (e.g., administering ear drops or ointments) without injury, and explains or demonstrates measures to maintain wellness of the external ear.

Middle Ear, Tympanic Membrane, and Mastoid Disorders

Infections

PATHOPHYSIOLOGY AND ETIOLOGY. Otitis media is the most common disease of the middle ear. Otitis media is a general term for inflammation of the middle ear mastoid, and eustachian tube. Inflammation of the nasopharynx causes most cases of otitis media. As inflammation occurs, the nasopharyngeal mucosa becomes edematous and discharge is produced. When fluid, pus, or air builds up in the middle ear, the eustachian tube becomes blocked, and this impairs middle ear ventilation.

There are several types of otitis media in which inflammation can occur alone, with infective drainage, or with noninfective drainage. The first type of otitis media is otitis media without effusion. This is an inflammation of the middle ear mucosa without drainage. The second type of otitis media occurs when there is a bacterial infection of the middle ear mucosa. This is called acute otitis media, suppurative otitis media, or purulent otitis media. The infected fluid becomes trapped in the middle ear. If the infection continues longer than 3 months, chronic otitis media results. The third type of otitis media is otitis media with effusion. Other names include serous otitis media, nonsuppurative otitis media, and glue ear. With this type of otitis media, noninfective fluid accumulates within the middle ear.

SIGNS AND SYMPTOMS. Acute otitis media commonly follows an upper respiratory infection. A fever, earache, and feeling of fullness in the affected ear are common symptoms (Table 52.10). As purulent drainage forms, pain and conductive hearing loss occur. Nausea and vomiting may also be present. Purulent drainage may be evident in the external ear canal if the tympanic membrane ruptures. Mastoid tenderness indicates that the infection has spread to the mastoid area. Otoscopic examination reveals a reddened, bulging tympanic membrane.

Symptoms of otitis media with effusion may go undetected in adults because there are no signs of infection. The patient may report fullness, bubbling, or crackling in the ear. The patient may have a slight conductive hearing loss or allergies or be a mouth breather. Otoscopic examination can reveal a bulging tympanic membrane with a fluid level, but the eardrum is not reddened.

COMPLICATIONS. A perforation may occur with an acute or chronic infection. Buildup of fluid and pressure in the middle ear can cause a spontaneous perforation of the tympanic membrane. The patient usually experiences pain before the rupture and relief of pain after the rupture. The fluid in the middle ear moves through the perforation into the ear canal, relieving the pressure and pain. A tympanic membrane perforation causes hearing loss. The location and size of the perforation determine the extent of hearing loss. Damage to the ossicles can also occur with perforation.

Repeated infections in the middle ear or mastoid can cause a cholesteatoma, which is an epithelial cystlike sac that fills with debris such as degenerated skin and sebaceous material. The cholesteatoma starts in the external ear canal and spreads to the middle ear through a perforation in the tympanic membrane. Damage occurs in the middle ear structures as a result of pressure necrosis. The cholesteatoma causes conductive hearing loss. As the disease progresses, facial paralysis and vertigo may occur.

Tympanosclerosis is another complication of repeated middle ear infections. Tympanosclerosis consists of deposits of collagen and calcium on the tympanic membrane. The condition can slowly progress over time to the area around the middle ear ossicles. These deposits appear as chalky white plaques on the tympanic membrane and contribute to conductive hearing loss.
Chapter 52 Nursing Care of Patients With Sensory Nervous System Disorders: Vision and Hearing

Mastoiditis can occur if acute otitis media is not treated. The infection spreads to the mastoid area, causing pain. The use of antibiotics has resulted in acute mastoiditis becoming relatively uncommon. Chronic mastoiditis is still seen with repeated middle ear infections.

**DIAGNOSTIC TESTS.** An elevated WBC count may be seen and cultures on ear drainage identify the specific infective organism. Conductive hearing loss is usually present on audiometric studies and Rinne, Weber, and whisper voice tests. Imaging studies may be done to diagnose infection.

**THERAPEUTIC MEASURES.** Bacterial infections are treated with topical and systemic antibiotics. Topical antibiotics may contain steroids to help with inflammation. Oral analgesics are given to control pain.

A modified Politzer ear device can be used to help equalize pressure in the middle ear and aid fluid drainage. The device, also known as the ear popper (www.earpopper.com), emits a stream of air into the nasal cavity that gently opens the eustachian tubes. This relieves negative pressure and allows pressure to equalize and fluid to drain.

Surgical intervention includes several techniques. Paracentesis may be performed with a needle and syringe. The tympanic membrane is punctured with the needle, and the fluid is drained from the middle ear. A myringotomy may also be performed. During this procedure, an incision is made in the tympanic membrane and fluid is allowed to drain out or is suctioned out of the middle ear. Another technique is laser-assisted myringotomy, which vaporizes the tympanic membrane. Various types of tristympanic tubes may be inserted to keep the incision open. The tristympanic tube keeps the incision in the tympanic membrane open, equalizes pressure, and prevents further fluid formation and buildup. The tristympanic tubes are left in place until the infection is cured. Most tubes spontaneously extrude in 3 to 12 months and rarely have to be removed.

Reconstructive repair of a perforated tympanic membrane is called a myringoplasty. One technique involves placing Gelfoam over the perforation. A graft from the temporal muscle behind the ear or tissue from the external ear is then placed over the perforation and Gelfoam. The Gelfoam is absorbed, and the graft repairs the perforation.

A mastoidectomy involves incision, drainage, and surgical removal of the mastoid process if the infection has spread to the mastoid area.

**Otosclerosis**

**PATHOPHYSIOLOGY AND ETIOLOGY.** Otosclerosis, or hardening of the ear, results from the formation of new bone along the stapes. With the new bone growth, the stapes becomes immobile and causes conductive hearing loss. The formation of the new bone growth begins in adolescence or early adulthood and progresses slowly. Hearing loss is most apparent after the fourth decade of life. Otosclerosis is more common in women than in men. The disease usually affects both ears. Although the exact cause of otosclerosis is not known, most patients have a family history of the disease. It is therefore thought to be a hereditary disease.

**SIGNS AND SYMPTOMS.** The primary symptom of otosclerosis is progressive hearing loss. The patient usually experiences bilateral conductive hearing loss, particularly with soft, low tones. Usually, medical treatment is sought when the hearing loss interferes with the patient’s ability to hear consonants. The patient may also experience tinnitus. Otoscopic examination reveals a pinkish orange tympanic membrane because of vascular and bony changes in the middle ear.

**DIAGNOSTIC TESTS.** Audiometric testing indicates the type and extent of the hearing loss. Imaging studies indicate the location and extent of the excessive bone growth. The whisper voice test and normal conversation show decreased hearing. The patient hears best with bone conduction in the Rinne test, whereas lateralization to the most affected ear occurs with the Weber test.

**THERAPEUTIC MEASURES.** There is no cure for otosclerosis, but hearing aids may be used to improve hearing for the patient. Although total restoration of hearing is not possible, reconstruction of necrotic ossicles is done to restore some of the patient’s hearing. Various methods are used to reposition and replace some or all of the ossicles. Unfortunately, the surgeries are not always successful over time. Ossiculoplasty is the reconstruction of the ossicles. Prostheses made of plastic, ceramic, or human bone are used to replace the necrotic ossicles. Total or partial ossicular replacement prosthesis may be used.

Stapedectomy is the treatment of choice for otosclerosis. Either part or all of the stapes is removed and replaced with a prosthesis. The prosthesis is placed between the incus and the oval window. Advances in surgical treatment include the use of lasers for improved visualization, less trauma, and greater precision during surgery. The goal is to restore vibration from the tympanic membrane to the oval window and allow sound transmission. Many patients experience improved hearing immediately, others not until swelling subsides. Complications of ossiculoplasty and stapedectomy include extrusion of the prosthesis, infection, hearing loss, dizziness, and facial nerve damage.

**NURSING CARE.** The operative ear is positioned upward when lying in bed. An earplug may be used to help keep the area aseptic; the proximity of the brain makes this necessary to prevent brain infection. Activity orders may vary. The patient may be dizzy and experience nausea. Antiemetics should be given promptly to prevent vomiting. The patient’s safety should be ensured if dizziness occurs. To prevent dislodgment or damage to the prosthesis, patients are instructed not to cough, sneeze, blow their nose, vomit, fly in an airplane, lift heavy objects, or shower. If the patient develops a cold, the HCP should be contacted.

**WORD • BUILDING •**

**myringoplasty:** myringo—tympanic membrane + plasty—surgical repair

**stapedectomy:** stape(s)—stirrup + ectomy—excision of
ETIOLOGY AND PHYSIOLOGY.

Trauma such as a blasting force, a blunt injury to the side of the head, or sudden changes in atmospheric pressure can cause the tympanic membrane to perforate and middle ear ossicles to fracture. Blast injuries cause injury from the direct pressure on the ear. Blunt injury to the head can cause temporal skull fractures and trauma to both the middle and inner ear. Baro-trauma caused by sudden changes in atmospheric pressure in the ears can occur during scuba diving and airplane takeoffs and landings. Pressure changes can occur during normal atmospheric conditions such as nose blowing, heavy lifting, and sneezing. During these rapid changes of pressure, the eustachian tube does not ventilate because of occlusion or dysfunction and a negative pressure develops in the middle ear. The resulting pressure can cause the tympanic membrane to rupture or cause damage to the middle and inner ear.

SIGNS AND SYMPTOMS. Pain and hearing loss are the most common symptoms associated with trauma. Other signs and symptoms of barotrauma include fullness of the ears, vertigo, nausea, disorientation, edema of the affected area, and hemorrhage in the external or middle ear. In severe cases of barotrauma when scuba diving, these symptoms can cause drowning or cerebral air embolism from an overly rapid ascent. Otoscopic examination may reveal a retracted, reddened, and edematous tympanic membrane.

DIAGNOSTIC TESTS. Audiometric studies are completed to determine the hearing loss. Imaging studies may be done to determine the extent of middle and inner ear damage. Conductive or sensorineural hearing loss may be evident, depending on the extent and location of the damage.

The middle ear and mastoid cavity cannot be visualized directly. The tympanic membrane is the only middle ear structure that can be directly visualized with an otoscope. Objective assessment also includes vital signs, noting an elevation in temperature. Any drainage from the ear should be noted and described. Hearing acuity is screened with the whisper voice, Rinne, and Weber tests.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.**

**Risk for Infection related to broken skin, pressure necrosis, chronic disease, or surgical procedure**

*Expected Outcome:* The patient will have no signs of infection (no drainage from ear, no tenderness over mastoid, negative culture, afebrile).

- Explain to patient not to blow nose by pinching off nares to prevent spread of upper respiratory infections up the eustachian tube.
- Teach patient not to insert anything into ear canal to prevent ear damage (see Box 52-4).
- Teach patient how to correctly remove cerumen from ear to prevent infection or damage.

**Acute Pain related to fluid accumulation, inflammation, or infection**

*Expected Outcome:* The patient will indicate pain is decreased or absent as evidenced by a lower rating on a pain scale.

- Monitor pain using a pain scale, and determine optimum analgesic schedule with patient to maximize pain control.
- Use nonpharmacological measures such as heat, distraction, and relaxation techniques for pain reduction.
- Teach patient how to administer ear drops or ear ointment to help resolve infection and decrease pain.
- Instruct patient to take all prescribed antibiotics, even after symptoms are relieved, to ensure that infection is completely resolved.

**Deficient Knowledge Regarding Hearing Loss and Lack of Information or Surgery related to lack of exposure to information due to no prior experience**

*Expected Outcome:* The patient will state an understanding of methods for preventing problems in the middle ear, tympanic membrane, and mastoid process or impending surgery.

- Teach patient to avoid trauma to the ear, loud noise exposure, and environmental or occupational conditions to prevent damage to the ear.
- Teach patient to yawn or perform jaw-thrust maneuver (opening mouth wide and moving jaw) to equalize ear pressure, which helps maintain ear health.
- Teach patient methods of effective communication to compensate for hearing loss (see the “Nursing Care Plan for the Patient With Hearing Loss”).
- Ask about patient’s knowledge regarding surgery to determine learning needs.
- Include family in teaching sessions to enhance learning and assist with retention of information.

- Provide preoperative and postoperative instructions to promote patient understanding (Box 52-5).
- Teach patient to avoid getting water in ear postoperatively to prevent moisture from reaching surgical site.

---

**Box 52-5 Preoperative and Postoperative Nursing Interventions for the Patient Having Ear Surgery**

**Preoperative Care**

Nursing care for the patient undergoing ear surgery begins as soon as the decision to have surgery is made. The nurse collects data, determines if the patient understands the events, notes the patient’s mental readiness, and obtains baseline physiological data.

- Ask understanding of the surgery and whether local or general anesthesia will be used.
- Help alleviate the patient’s fear by encouraging the patient to ask questions. Ensure that all questions are answered before the surgery by appropriate person.
- Explain the type of pain, any packing or dressings that may be in place postoperatively, and any other postoperative restrictions that may be needed.
- Establish baseline vital signs and document findings.
- Ensure that the operative permit is signed.
- Determine current medications the patient is taking and document in the patient’s record.
- Determine if the patient understands that surgery does not always correct impaired hearing.
- Leave any hearing devices in place as long as possible before the surgery.

**Postoperative Care**

Postoperatively the nurse is responsible for assessing the patient’s physiological status. The nurse is also responsible for ensuring that the patient and family members understand discharge instructions.

- Some degree of pain may be expected, even with minor procedures. Explain how and when to take pain medication when the patient is discharged.
- Monitor postoperative vital signs and return to presurgical baseline.
- Tell patients that if an occlusive dressing is in place, hearing may be decreased until the dressing is removed.
- Instruct patients with tubes to avoid getting water in the ear. A shower cap or earplugs may be used.
- Instruct the patient to seek medical attention if excessive bleeding or drainage occurs. If a cotton plug is to be left in place, instruct the patient to change it daily.

Continued
UNIT FOURTEEN Understanding the Sensory System

Box 52-5 Preoperative and Postoperative Nursing Interventions for the Patient Having Ear Surgery—cont’d

- Teach the patient, unless contraindicated, to blow the nose very gently one side at a time for the first week after surgery. Instruct the patient to sneeze or cough with the mouth open for 1 week after surgery.
- Avoid airplane flights for 1 week after surgery. For sensations of ear pressure, hold nose, close mouth, and swallow to equalize pressure.
- The patient should avoid strenuous work for several weeks. The patient may return to work in a few days, depending on the type of surgery and the type of work the patient does.
- Tell the patient to take prescribed medication and antibiotics as ordered.
- Have the patient arrange for a follow-up appointment by calling HCP’s office.

EVALUATION. The goals for the patient are met if there is no ear drainage or pain over mastoid and if the patient has negative culture and remains afebrile, states that no pain is present or pain is decreased, verbalizes care of ears and methods to prevent further infection, describes signs requiring medical attention, and verbalizes the rationale and outcome for any upcoming surgery as well as preoperative and postoperative instructions.

Inner Ear
Labyrinthitis

PATHOPHYSIOLOGY AND ETIOLOGY. Labyrinthitis is an inflammation or infection of the inner ear and can be caused by either viral or bacterial pathogens. The bacterium or virus enters the inner ear from the middle ear, meninges, or bloodstream. Serous labyrinthitis is a type of acute labyrinthitis that sometimes follows drug intoxication or overindulgence in alcohol. It can also be caused by an allergy. Diffuse suppurative labyrinthitis occurs when acute or chronic otitis media spreads into the inner ear or after middle ear or mastoid surgery. Destruction of soft tissue structures from the infection can cause permanent hearing loss.

SIGNS AND SYMPTOMS. Vertigo, tinnitus, and sensorineural hearing loss are the most common symptoms. Vertigo, or dizziness, occurs when the vestibular structures are involved. Tinnitus, or ringing in the ear, occurs when the infection is located in the cochlea. Sensorineural hearing loss can be caused by infections in the cochlea or vestibular structures. Nystagmus on the affected side may occur. Other signs and symptoms include pain, fever, ataxia, nausea, vomiting, and beginning nerve deafness.

DIAGNOSTIC TESTS. A CBC is done to diagnose infection. A hearing evaluation by an audiologist may reveal mild to complete hearing loss. Rinne and Weber tests indicate conductive or sensorineural hearing loss.

THERAPEUTIC MEASURES. Antibiotics are used to treat bacterial inner ear infections. Viral infections usually run their course in about 1 week. Mild sedation may help the patient relax. Although there is no specific medicine to relieve dizziness, antihistamines can be used if they prove helpful on an individual basis. Patients may be placed on bed rest.

NURSING CARE. Nursing care focuses on preparing the patient for surgery and adjusting to the diagnosis and the resulting hearing loss (see Box 52-5).

Ménière’s Disease

PATHOPHYSIOLOGY AND ETIOLOGY. Ménière’s disease is a balance disorder. Its cause is unknown. With the disease, there is a dilation of the membranous labyrinth resulting from a disturbance in the fluid physiology of the endolymphatic
The exact etiology is unknown but is thought to stem from hypersecretion, hypoabsorption, deficit membrane permeability, allergy, viral infection, hormonal imbalance, or mental stress. The disease usually develops between ages 40 and 60. The symptoms range from vague to severe and debilitating.

**SIGNS AND SYMPTOMS.** A triad of symptoms of vertigo, hearing loss, and tinnitus characterizes Ménière's disease. Recurring episodic bouts of the incapacitating triad of symptoms and nausea and vomiting occur with Ménière's disease. The attacks may occur suddenly, or the patient may experience warning signs such as headache or fullness in the ears. During an acute episode, the patient experiences vertigo that lasts 2 to 4 hours. The vertigo is usually accompanied by nausea and vomiting, followed by dizziness and unsteadiness. The patient is uncoordinated and has gait changes when walking. Hearing loss is often described as a fluctuating fullness in the ears. Vital signs usually remain normal. It takes several weeks for symptoms to resolve, and hearing loss in the affected ear remains. The patient then enters a stage of remission until the next attack. The acute episodes occur two to three times yearly. Eventually the patient has complete remission with some degree of permanent hearing loss.

**DIAGNOSTIC TESTS.** Audiometric studies identify the type and magnitude of the hearing loss. Neurologic testing and radiographic studies are done to rule out other pathological conditions. A caloric stimulation test may demonstrate a difference in eye movement.

**THERAPEUTIC MEASURES.** Medical treatment consists of symptomatic treatment for acute attacks and prophylactic treatment between attacks. Tranquilizers and vagal blockers may be needed during acute attacks. Salt-restricted diet, diuretics, antihistamines, and vasodilators are used during prophylactic treatment. The patient should avoid alcohol, caffeine, and tobacco use. The patient may be placed on bed rest during acute attacks. The goals of medical treatment are to preserve hearing and reduce symptoms. Some patients who do not respond to treatment may be placed on lower doses of methotrexate.

Surgical treatment is used only when medical management has failed. When involvement is unilateral, a labyrinthectomy can be performed. This causes complete loss of hearing in that ear. Another surgical intervention establishes a shunt from the inner ear to the subarachnoid space. This procedure helps drain the fluid and prevent future hearing loss. Another surgical treatment is intratympanic gentamicin injection, which is usually done in the HCP's office.

**NURSING CARE.** Nursing management focuses on managing the patient's symptoms and providing safety during the acute attacks. Because of the unpredictability of Ménière's disease, the nursing care focuses on emotional support for the patient during periods of remission. Provide emotional support and resources to help the patient cope with the unpredictable nature of the disease and the physical impairments associated with the disease.

**Nursing Process for the Patient With Inner Ear Disorders**

**DATA COLLECTION.** Table 52.12 reviews subjective data to be collected. Objective data include examination of gross hearing, the whisper voice, Rinne, and Weber tests, a physical examination, and lab data. The patient should be assessed for any nutritional deficiencies, including dehydration, weight loss, or weight gain. An unsteady gait or temperature is also noted.

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.
Planning focuses on helping the patient maintain a normal lifestyle, remain free of injuries, cope with the illness or hearing loss, and maintain adequate nutrition and hydration. The major nursing diagnoses and interventions for internal ear disorders include those discussed next.

**Anxiety related to unpredictability of sudden and severe acute attacks**

**Expected Outcome:** The patient will state that anxiety is decreased.

- Encourage patient to express concerns about hearing loss and the unpredictability of acute attacks to identify causes of anxiety.
- Assess for signs of anxiety such as fidgeting, restlessness, apprehension, shakiness, and increased heart rate to determine if anxiety is present.
- Explore with patient techniques that have and have not worked in the past to determine which techniques to use to reduce anxiety.
- Use a calm reassuring approach to help instill confidence.
- Provide quiet environment and diversional activities to calm patient.
- Provide factual information regarding diagnosis and treatment to promote understanding and reduce anxiety.

**Risk for Injury related to impaired equilibrium**

**Expected Outcome:** The patient will not be injured from falling due to alterations in equilibrium.

- Institute fall precautions to help prevent injury.
- Ensure that environment is safe and free of obstacles (throw rugs, electrical cords in walkways, and poor lighting) to prevent falls.
- Monitor for signs of headache or fullness in the ears to detect oncoming Ménière’s disease attack.
- Instruct patient to avoid sudden movement of the head during periods of vertigo to prevent increasing symptoms.
- Instruct patient on correct dosage and administration of medications to help ensure resolution of symptoms.
- Instruct patient to avoid use of alcohol, caffeine, and tobacco to decrease disruptions of equilibrium.

**Nutrition: Less Than Body Requirements related to nausea and vomiting**

**Expected Outcome:** The patient will experience adequate nutrition and hydration with relief of nausea and vomiting.

- Monitor for signs of nausea, vomiting, and inadequate hydration to determine baseline information.
- Instruct patient to use deep breathing, voluntary swallowing, and eating slowly to suppress the vomiting reflex.
- Medicate as ordered to relieve symptoms and prevent episodes of nausea and vomiting.
- Institute salt-restricted diet, if ordered, and instruct patient on low- and high-sodium foods to reduce fluid retention.

**EVALUATION.** The goals for the patient have been met if signs of anxiety are decreased and if the patient remains free from injury and maintains weight within normal range with no signs of dehydration.

---

**CRITICAL THINKING**

**Mrs. Belmont**

Mrs. Belmont is a 48-year-old woman diagnosed with Ménière’s disease. She is currently in a state of remission. She states that she is fearful that the next attack will occur during her daughter’s upcoming wedding.

1. What information would you ask of Mrs. Belmont about her attacks?
2. What instructions can you provide her regarding treatment during her attacks?
3. How will you handle Mrs. Belmont’s fears about future attacks?

*Suggested answers are at the end of the chapter.*
CRITICAL THINKING

■ Mr. Samuel
1. Mr. Samuel should seek assistance, patch both eyes, and have someone take him to receive medical treatment immediately.
2. Ensure that an antiemetic is ordered postoperatively on the patient’s return to the unit. When Mr. Samuel reports nausea, the antiemetic should be given promptly.
3. Did you recognize that the concentration is 2 mg/1 mL, and the volume of the vial is 2 mL? The concentration is what is needed to calculate the dose:
\[
\frac{4 \text{ mg}}{1 \text{ mL}} \times \frac{1 \text{ mL}}{2 \text{ mg}} = 2 \text{ mL}
\]

■ Mrs. Springhorn
1. Gain her attention, face and stand in her visual field, avoid glare, speak clearly, inform her of topics to be discussed, assess for understanding, allow extra time, reduce background noises, use nonverbal communication, and do not cover your mouth when talking.
2. Use active listening. Use written communication to enhance spoken words. Use demonstration and return demonstration. Allow questions. Do not hurry. Provide information in short segments. Reassess understanding at each session.
3. Place the operative ear upward when lying in bed. Use earplug as ordered. Do not cough, sneeze, blow nose, vomit, fly in an airplane, lift heavy objects, or shower. If a cold develops, call the HCP. If dizzy, be careful when standing up.

■ Mrs. Belmont
1. You would ask Mrs. Belmont about specific signs she may have before attacks, such as headache or fullness in the ears. You should also ask her specifically what symptoms she has during attacks. Common symptoms include the triad of vertigo, hearing loss, and tinnitus. She may also have nausea, vomiting, and unsteady gait.
2. Discuss treatment that Mrs. Belmont has used with previous attacks. Ask her which treatments seemed to help. Common treatments you can recommend include taking recommended medication such as tranquilizers and vagal blockers; instruct her to maintain adequate fluid and nutritional intake during attacks; ambulate with assistance; limit salt in diet; avoid alcohol, caffeine, and tobacco use.
3. Discuss with Mrs. Belmont prophylactic treatment such as salt-restricted diet, diuretics, antihistamines, and vasodilators. Discuss the normal progress of the disease. Provide emotional support and discuss methods to help her cope with the disease, such as counseling and relaxation techniques.
REVIEW QUESTIONS

1. The nurse is caring for a patient who is diagnosed with otosclerosis. The patient asks the nurse what this disease is. Which is the most appropriate response by the nurse?
   1. “Infection of the external ear commonly caused by moisture.”
   2. “Tumor of the eighth cranial nerve.”
   3. “Hardening of the stapes due to new bone growth.”
   4. “Inflammation of the inner ear caused by pathogens.”

2. The nurse is caring for a patient who is diagnosed with a refractive error. The patient asks the nurse what this means. What would be the appropriate explanation by the nurse?
   1. “You will lose your vision and become blind.”
   2. “You will need corrective lenses in order to see clearly.”
   3. “The pressure in your eyes is higher than normal.”
   4. “Your vision is 20/20.”

3. A patient comes to the health clinic for a suspected ear infection. Which of the following data collection findings does the nurse expect with an external ear infection?
   1. Pain
   2. Fullness in ears
   3. Fever
   4. Dizziness

4. A patient has been prepped for an internal eye examination. Anesthetic drops and a mydriatic drug have been administered. Which of the following should the patient be taught for eye safety following the examination?
   1. “Wear sunglasses after the exam.”
   2. “Rub your eye hourly to increase blood circulation.”
   3. “You may reapply contact lenses when the eye exam is completed.”
   4. “Flush your eye with water to remove the eye drops.”

5. The nurse cares for patients after eye surgery. Which of the following patients would the nurse provide specific positioning instructions to after eye surgery to prevent complications?
   1. 19-year-old after removal of congenital cataract
   2. 30-year-old woman after pneumatic retinopexy
   3. 52-year-old man after trabeculectomy
   4. 82-year-old man after corneal transplant

6. The nurse is caring for a patient with a history of acute angle-closure glaucoma. The nurse is preparing to administer the patient’s medications. Which medications should the nurse question before administration?
   1. Morphine
   2. Cefazolin (Kezol)
   3. Atropine
   4. Ranitidine (Zantac)
   5. Hydroxyzine (Vistaril)
   6. Warfarin (Coumadin)

7. The nurse is assisting with discharge instructions for a patient. For which of the following medications would the nurse teach the patient that the medication can cause hearing loss?
   1. Furosemide (Lasix)
   2. Acetaminophen (Tylenol)
   3. Warfarin (Coumadin)
   4. Penicillin (Pen-Vee K)

8. The nurse is caring for a patient with macular degeneration. During data collection, which symptom would the nurse anticipate the patient to report?
   1. Loss of peripheral vision
   2. Sudden darkness
   3. Dull ache in the eyes
   4. Loss of central vision

9. The nurse is contributing to the plan of care for a patient with Ménière’s disease. What is the primary goal for a patient with Ménière’s disease that the nurse should recommend to include in the plan of care?
   1. Prevent dehydration
   2. Decrease pain
   3. Prevent injury
   4. Preserve hearing

10. The nurse is caring for a patient with presbycusis. Which technique is most important for the nurse to use to increase communication with this patient?
    1. Talk in a very loud voice.
    2. Lower voice pitch.
    3. Do not smile or chew gum when talking to the patient.
    4. Allow extra time for patient to respond.

11. A patient with acute angle-closure glaucoma reports use of the following medications. The use of which of these medications indicates to the nurse that the patient requires further instruction?
    a. Acetaminophen
    b. Cefazolin (Kezol)
    c. Ranitidine (Zantac)
    d. Diphenhydramine (Benadryl)

Answers can be found in Appendix C.
unit FIFTEEN

Understanding the Integumentary System
KEY TERMS
alopecia  (AH-loh-PEE-sh-uh)
eccymosis  (EK-ih-MOH-siss)
erythema  (AIR-ih-THEE-mah)
petechiae  (peh-TEE-kee-eye)
turgor  (TUR-gur)

LEARNING OUTCOMES
1. Explain the normal structures and functions of the integumentary system.
2. Identify the effects of aging on the integumentary system.
3. List data to collect when caring for a patient with an integumentary system disorder.
4. Identify laboratory and diagnostic tests commonly performed to diagnose integumentary disorders.
5. Describe therapeutic measures that are used for patients with integumentary disorders.
NORMAL INTEGUMENTARY SYSTEM ANATOMY AND PHYSIOLOGY

The skin, its accessory structures, and the subcutaneous tissue form the integumentary system, the covering of the body that separates the living internal environment from the external environment. The skin itself is considered an organ and consists of two layers: the outer epidermis and the inner dermis (Fig. 53.1).

Epidermis, Dermis, and Hypodermis

The epidermis has up to five epithelial layers. The innermost epidermal layer is called the stratum germinativum, where mitosis occurs to produce new epidermal cells. The rate of mitosis is fairly constant, but increases from chronic abrasion to the skin, as in callus formation. The new cells, keratinocytes, produce the protein keratin and a water-repelling sealant. As they are pushed to the surface of the skin, they die and become the stratum corneum, the outermost of the epidermal layers. These cells resist abrasion and water entry and exit.

The stratum corneum consists of many layers of dead, keratinized cells. An unbroken stratum corneum is an effective barrier against pathogens and most chemicals, although even microscopic breaks are sufficient to permit their entry. As dead cells are worn off the surface of the skin (which contributes to the removal of pathogens), they are continuously replaced by cells from beneath. Loss of large portions of the stratum corneum, as with extensive third-degree burns, greatly increases the risk for infection and dehydration.

Melanocytes are cells in the lower epidermis that produce the protein melanin. The amount of melanin is a genetic characteristic and gives color to skin and hair. When the skin is exposed to ultraviolet (UV) rays from the sun or artificial lighting, production of melanin increases, and it is incorporated into the epidermal cells making the cells darker. Melanin is a pigment barrier to prevent further exposure of living cells in the stratum germinativum to UV rays. UV rays are mutagenic; that is, they are capable of damaging the DNA in cells and causing mutations that can result in malignancy.

Also in the epidermis are Langerhans cells, a type of macrophage that presents foreign antigens to immune cells. This is the first step in the destruction of pathogens that penetrate the epidermis.

Extensive collagen fibers in the dermis give the skin its strength as an organ. Elasticity results from widespread elastic fibers and allows stretched skin to return to its proper position.

The hypodermis is areolar and adipose tissue. This subcutaneous adipose tissue cushions, insulates, and stores energy as triglyceride. The subcutaneous tissue contains...
abundant leukocytes that destroy pathogens that enter through broken skin.

**Hair**

Human hair with significant function includes the eyelashes and eyebrows, which keep dust and sweat out of the eyes, and nostril hair, which filters air entering the nasal cavities. Hair on the head provides thermal insulation (Figure 53.2).

**Nails**

Nail roots are found at the ends of the fingers and toes; growth of nails is similar to growth of hair. Mitosis in the nail root is a continuous process to produce new, keratinized cells. As these cells die, they form the visible nail. Nails protect the ends of the digits from mechanical injury and are useful for picking up small objects.

**Receptors**

Sensory receptors for the cutaneous senses reside in the dermis. Receptors for heat, cold, and pain are free nerve endings; encapsulated nerve endings are specific for touch and pressure. The sensitivity of an area of skin is determined by the density of receptors present.

**Glands**

Cutaneous exocrine glands lie within the dermis and secrete to the surface of the skin through ducts. These include sudoriferous glands (both eccrine and apocrine), sebaceous glands, ceruminous glands (cerumen), and ciliary glands (tears) (Figure 53.3).

Water lost to eccrine gland secretion, at minimum, is about 500 mL per day through insensible perspiration. Excessive loss can rise to a liter per day in extreme heat or during vigorous exercise. Such dehydration and electrolyte loss must be replaced to avoid potential imbalances.

**Blood Vessels**

Blood vessels in the dermis serve the usual function of tissue nourishment, but the arterioles are also involved in maintaining body temperature. Blood carries heat produced by active organs and distributes it throughout the body. In a warm environment, dilation of blood vessels in the dermis increases blood flow and loss of heat to air. Constriction of blood vessels in a cold environment decreases blood flow to the skin and conserves body heat.

Stressful situations also cause vasoconstriction in the dermis, which allows blood to circulate to more vital or gans, such as the heart, liver, brain, or muscles.

Other functions of the skin are the formation of vitamin D from cholesterol when the skin is exposed to the UV rays of the sun, and the excretion of small amounts of ammonia, urea, and sodium chloride in sweat.

**Aging and the Integumentary System**

The effects of age on the integumentary system are often quite visible. Figure 53.4 summarizes the effects of aging.
Eccrine glands
- Contain a duct that leads from a secretory portion (consisting of a twisted coil in the dermis), through the dermis and epidermis, and onto the skin’s surface
- Are widespread throughout the body, but are especially abundant on the palms, soles, forehead, and upper torso
- Produce a transparent, watery fluid called sweat, which contains potassium, ammonia, lactic acid, uric acid, and other wastes
- Sweat plays a chief role in helping the body maintain a constant core temperature and also helps the body eliminate wastes.

Sebaceous glands
- Contain a duct that leads to a hair follicle (as opposed to opening onto the skin’s surface)
- Are located mainly in the axillary and anogenital (groin) regions
- Are scent glands that respond to stress and sexual stimulation
- Begin to function at puberty
- Sweat produced by these glands does not have a strong odor unless it accumulates on the skin; when this occurs, bacteria begins to degrade substances in the sweat, resulting in body odor.

Apocrine glands
- Contain a duct that leads to a hair follicle (as opposed to opening onto the skin’s surface)
- Are located mainly in the axillary and anogenital (groin) regions
- Are scent glands that respond to stress and sexual stimulation
- Begin to function at puberty
- Sweat produced by these glands does not have a strong odor unless it accumulates on the skin; when this occurs, bacteria begins to degrade substances in the sweat, resulting in body odor.

NURSING ASSESSMENT OF THE INTEGUMENTARY SYSTEM

Health History
Skin problems are a fairly common reason for a patient to enter the health system. Many factors can influence the integumentary system. A skin problem may be the only problem the patient has, or it may be a manifestation of an underlying systemic condition or psychological stress. Most important, the skin can visibly communicate the patient’s health. Therefore, questions that are posed to the patient are important in determining if the skin problem is a disease entity of its own or a sign of a more systemic disorder. Table 53.1 provides examples of general questions that can be asked of the patient to gather information.

If further assessment of a particular problem area is needed, the WHAT’S UP? line of questioning can be used. For example, if the patient has a rash, you can respond by pursuing the following information:
- Where is it? Is that the only area where you have a rash?
- How does it feel? Does it itch? Burn? Hurt?
- Aggravating and alleviating factors. Does scratching aggravate it? Does anything else aggravate it, such as soaps and detergents? What relieves it? How have you treated it in the past?
- Timing. How long have you had this problem? Does it recur?
- Severity. How bad is the discomfort on a scale of 0 to 10, with 0 being comfortable and 10 being unable to touch the area?
- Useful other data. Do you have other symptoms besides the rash?
- Patient’s perception. What do you think is causing your rash?

Physical Examination
Examination of the skin involves not only the entire skin area, but also the hair, nails, scalp, and mucous membranes. The main techniques used in physical examination of the skin are inspection and palpation. Make sure the patient is undressed but adequately draped in a well-lighted and warm environment. Use a handheld magnifying glass or penlight to see small details and light the area being inspected.

Normally the skin is intact, with no abrasions, and is smooth, dry, well hydrated, and warm. Skin turgor (tension) is firm and elastic. The skin surface is flexible and soft. Skin color ranges from light to ruddy pink or olive in
white-skinned patients and light brown to deep brown in dark-skinned patients.

Be aware of normal developmental changes when performing an examination. The skin of the neonate is very thin and friable (easily broken). During adolescence, the skin becomes thicker, with active sebaceous, eccrine, and apocrine glands. Body hair also changes during adolescence as a result of hormonal influences. In older patients, the skin loses some of its elasticity and moisture. There is decreased activity of sebaceous and sweat glands. The older patient’s skin is thinner, more fragile, and more wrinkled.

**Inspection**

Inspect each area of the skin, including nails, hair scalp, and mucous membranes, for color, moisture, lesions, edema, intactness, vascular markings, turgor, and cleanliness. This examination should be done in an orderly sequence, such as hair, scalp, nails, buccal mucosa, and then the general skin surface from head to toe.

**COLOR.** Skin color can be influenced by many factors, including the temperature of the patient, oxygenation, blood flow, exposure to UV rays, and positioning. Because skin color can differ genetically from very light to very dark, skin assessment can be difficult for the novice practitioner. Commonly noted alterations can include pallor, erythema (redness), jaundice, cyanosis, and brown color. Pallor is paleness or decrease in color and can be caused by vasoconstriction, decreased blood flow, or decreased hemoglobin levels.

---

<table>
<thead>
<tr>
<th>Category</th>
<th>Questions to Ask During the Health History</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>History</td>
<td>Do you (or does anyone in your family) have a history of dryness, rashes, itching, skin disease, psoriasis, eczema, dermatitis, asthma, hay fever, hives, or allergies?</td>
<td>These conditions may be hereditary.</td>
</tr>
<tr>
<td>Risk Factors</td>
<td>Have you noticed any changes in your skin, such as a sore that does not heal, rashes, lumps, or a change in an existing mole?</td>
<td>Sores that do not heal, moles that change color, or lumps may indicate cancer. Slow healing can also be associated with diabetes. Brown staining of the skin in the lower legs is associated with venous stasis. A break in skin integrity can lead to infection. Repeat sunburns and tanning are a risk factor for skin cancer.</td>
</tr>
<tr>
<td></td>
<td>Have you had any recent trauma to your skin? Do you have a tendency to sunburn easily? Do you use sunblock? Do you go to tanning salons or use a sun lamp?</td>
<td></td>
</tr>
<tr>
<td>Hair</td>
<td>Do you wear a wig or hairpiece?</td>
<td>Adequate examination of the scalp requires permission for removal of a wig or hairpiece. Hair loss can result from systemic illness or treatment or sometimes from infections or hair care products.</td>
</tr>
<tr>
<td></td>
<td>Have you noticed a change in the growth or loss of your hair?</td>
<td></td>
</tr>
<tr>
<td>Nails</td>
<td>Have you experienced recent trauma or changes in your nails? Do you wear artificial nails?</td>
<td>Nail changes may be caused by circulatory problems. Artificial nails may mask changes.</td>

</tbody>
</table>

from anemia. Pallor is best assessed on the face, conjunctivae, nailbeds, and lips. Erythema, or red discoloration, can be caused by vasodilation or increased blood flow to the skin from fever or inflammation. Erythema is best assessed on the face or in an area of trauma.

Jaundice, a yellow-orange discoloration, can result from liver disease. Although skin is affected by jaundice, the best place to inspect for jaundice is in the sclera of the eye. Cyanosis, or bluish discoloration, can indicate a cardiac, pulmonary, or perfusion problem. The best places to inspect for cyanosis are the lips, nailbeds, conjunctivae, and palms. People of Mediterranean descent normally have a bluish tone to their lips; this is not cyanosis.

A brown color in an otherwise light-skinned patient may be caused by increased melanin production and can indicate chronic exposure to sunlight, or pregnancy. This is best assessed on areas exposed to the sun; changes in pregnancy can be seen on the face, areolae, and nipples. A brownish color also may result from chronic peripheral vascular disease, especially noted on the lower legs.

LESIONS. A lesion is any change or injury to tissue. Assessment of skin lesions helps determine the cause of a skin disorder. Lesions are described as primary or secondary. Primary lesions are the initial reaction to a disease process. Secondary lesions are changes that take place in the primary lesion because of trauma, scratching, infection, or various stages of a disease. Lesions are further described according to type and appearance in Figure 53.5.

When assessing and documenting skin lesions, note the color or colors of the lesion and the size (usually in centimeters), location, distribution, and configuration. Configuration refers to the pattern of the lesions, as shown in Figure 53.6. Also note any exudate, including amount, color, and odor, and any accompanying symptoms. Gently stretching the skin over the affected area makes lesions stand out more for further assessment.

In general, healthy patients with naturally dark skin have a reddish undertone, with pinkish buccal mucosa, tongue, nails, and lips. If a dark-skinned patient is pale, the mucous membranes have an ash-gray color, lips and nailbeds appear paler...
### PRIMARY LESIONS

<table>
<thead>
<tr>
<th>Lesion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macule</td>
<td>Flat, nonpalpable change in skin color, with different sizes, shapes, color; usually smaller than 1 cm (e.g., rubella, scarlet fever, freckles)</td>
</tr>
<tr>
<td>Papule</td>
<td>Palpable solid raised lesion that is less than 1 cm in diameter due to superficial thickening in the epidermis (e.g., ringworm, wart, mole)</td>
</tr>
<tr>
<td>Nodule</td>
<td>Solid elevated lesion that is larger and deeper than a papule (e.g., fibroma, intradermal nevi)</td>
</tr>
<tr>
<td>Vesicle</td>
<td>A small, blisterlike raised area of the skin that contains serous fluid, up to 1 cm in diameter (e.g., poison ivy, shingles, chickenpox)</td>
</tr>
<tr>
<td>Bulla</td>
<td>A fluid-filled vesicle or blister larger than 1 cm (e.g., burns, contact dermatitis)</td>
</tr>
<tr>
<td>Pustule</td>
<td>Small elevation of skin or vesicle or bulla that contains lymph or pus (e.g., impetigo, scabies, acne)</td>
</tr>
<tr>
<td>Wheal</td>
<td>Round, transient elevation of the skin caused by dermal edema and surrounding capillary dilatation; white in center and red in periphery (e.g., hives, insect bites)</td>
</tr>
<tr>
<td>Plaque</td>
<td>A patch or solid, raised lesion on the skin or mucous membrane that is greater than 1 cm in diameter (e.g., psoriasis)</td>
</tr>
<tr>
<td>Cyst</td>
<td>A closed sac or pouch which consists of semisolid, solid, or liquid material (e.g., sebaceous cyst)</td>

**FIGURE 53.5** Description of skin lesions.
and scaling of the skin can indicate dry skin, or an inflammatory disorder.

**EDEMA.** Edema occurs because of a buildup of fluid in the tissues. Edema can cause the skin to become stretched, dry, and shiny. Examine and document the location, distribution, and color of edematous areas. If edema is unilateral, compare it with the opposite side of the body. Measure edematous extremities to track improvement or worsening of the condition. Dependent edema is edema that occurs in the part of the body that is at the lowest point, typically noted in the feet and ankles or in the sacrum if the patient is lying down.

**VASCULAR MARKINGS.** Vascular markings can be classified as normal and abnormal. Two common abnormal vascular changes are **petechiae** and **ecchymosis** (see Figures 28.1 and 28.5 in Chapter 28). Petechiae are reddish purple hemorrhagic spots that are smaller than 0.5 mm in diameter. In the darker skinned patient, petechiae are usually not visible on the skin but can be visualized in the conjunctiva and oral mucosa. Ecchymosis is a bruise that changes color from blue-black to greenish brown or yellow over time.

**GENERAL INTEGRITY AND CLEANLINESS.** Examine the integrity of the skin. Older adults have thin, fragile skin that is easily broken or torn. Be sure to check between toes and skinfolds and under a pendulous abdomen or breasts. Check over bony prominences for signs of pressure. Note general cleanliness and odors.

**Palpation**

Palpation is used with inspection. Use the dorsum (back) of the hand to palpate temperature because this part of the hand is most sensitive to changes in temperature. Use the fingertips to gently palpate over the skin to determine size, contour (flat, raised, depressed), and consistency (soft or indurated) of lesions. If a lesion is moist or draining, wear gloves to protect against the spread of infectious organisms. Note the degree of pain or discomfort associated with light palpation of lesions.

Examine for turgor and observe the texture of the skin. Skin turgor is a measure of the amount of skin elasticity. To assess for turgor, pinch the skin on the back of the forearm or over the sternum between the thumb and forefinger and then release. Normally, the skin lifts easily and then quickly returns to its normal state. Poor skin turgor is indicated by “tenting” of the skin, with more gradual return to its normal state. Poor skin turgor can indicate dehydration. Normal aging of skin produces some loss of skin elasticity; the preferred place to check skin turgor in older adults is over the sternum.

If edema is suspected, palpate those areas to assess for tenderness, mobility, and consistency. Press the edematous area (against bone, if possible) with your thumb for 5 seconds and then release. When pressure from your fingers leaves an indentation, this is called pitting edema. If the edema is in an...
extremity, measure and record the circumference in centimeters, and monitor it for increase or decrease in size.

Inspect and/or palpate over the entire body for hair color, quantity, thickness, and texture. Note any areas of alopecia (hair loss). Determine any recent changes in color and growth pattern. Note cleanliness, redness, scaling, flake, and tenderness. If lesions or lice are suspected, use disposable gloves to avoid spread of infection.

Terminal hair is the hair on the scalp, eyebrows, axillae, and pubic areas and on the face and chest of men. Vellus hairs are the soft, tiny hairs covering the body. Normally, body hair has a uniform distribution. Note male or female pubic hair distribution. Scalp hair can normally be thick, thin, coarse, smooth, shiny, curly, or straight. Describe scalp hair distribution and cleanliness.

Nails can reflect the patient’s general health. Examine fingers and nails for color, shape, texture, thickness, and abnormalities. Normally, the nails appear pink, smooth, hard, and slightly convex (160-degree angle), with a firm base. The nails of older adults may have a yellowish gray color, thickening, and ridges. Brown or black pigmentation between the nail and nail base is normal in dark-skinned patients. Abnormal findings include clubbing, which may indicate hypoxia, and spoon nails (conca ve nails, also called koilonychia), which can be associated with anemia. Thick nails may indicate fungal infection. Palpate for nail consistency, and observe for redness, swelling, or tenderness around the nail area. Table 53.2 describes other nail abnormalities.

Describe any abnormal skin conditions in detail. Include findings such as color of lesion, pain, swelling, redness, location, size, drainage (including amount, color, and odor), and eruption patterns. If equipment is available, an excellent way to supplement documentation is by photographing the area; serial photographs can be mounted in the chart to document healing progression. “Gerontological Issues” describes assessment and care specific to older adults.

Gerontological Issues

In acute care settings, priorities are determined by medical diagnoses and often center around cardiovascular, respiratory, nutrition, comfort, or other immediate concerns. The feet may be forgotten in the rush to care for the patient and plan a timely discharge.

Feet are also viewed by some as dirty, and washing the feet may be seen as a lowly job. It may be assumed that people take care of their own feet. However, many older people are unable to bend down or bring the feet up high enough to see or care for them.

For these reasons it is especially important for the nurse to assess and care for the feet, both in institutional settings and at home. General guidelines for assessment include the following:

- Inspect feet for redness or pressure ulcers over bony prominences.
- Inspect feet for dryness or cracking.
- Inspect between toes for cracking, wounds, or excess moisture.
- Inspect and palpate for calluses.
- Inspect toenails for thickening.
- Palpate dorsalis pedis and posterior tibial pulses for circulatory status.
- Assess patient’s sensation using a wisp of cotton, monofilament, or light touch.

Hints to promote healthy feet:

- Soak the patient’s feet briefly in warm water and wash using a gentle soap. Test the water to be sure it is not too warm, especially for the patient with reduced sensation.
- Thoroughly dry the feet, including between the toes. Water left to evaporate can cause drying and cracking.
- Use a pumice stone to help remove dry dead skin over heels or calluses. Work gently, rubbing the stone in one direction only and removing only a small amount of dead skin at any one time.
- Use a cream or lotion that does not contain alcohol to moisturize the feet. Do not apply between toes. Apply it with gentle massage while moving the patient’s feet through range-of-motion exercises. To prevent falls, never apply lotion before the patient steps into the tub or shower.
- Use gauze or a commercially made pad to decrease pressure and friction in areas between toes that cross or other areas where breakdown is likely.
- Encourage the patient to wear cotton or dry weave socks that allow feet to stay dry with perspiration.
- Encourage the patient to wear comfortable leather shoes or hard-soled slippers to avoid injury to the feet and prevent falls. Patients with diabetes should be encouraged to wear closed-toe shoes.
- Take extra care to assess and care for feet in patients with diabetes because of their increased risk for injury and slow healing.
DIAGNOSTIC TESTS FOR THE INTEGUMENTARY SYSTEM

Laboratory Tests

Cultures

Skin cultures are done to determine the presence of fungi, bacteria, and viruses. When a fungal infection is suspected, gently scrape scales from the lesion into a Petri dish or other indicated container. The specimen is then treated with a 10% potassium hydroxide solution to make fungi more prominent. The specimen can remain at room temperature until sent to the laboratory.

If a viral culture is ordered, the fluid is expressed (gently squeezed) from an intact vesicle, collected with a sterile cotton swab, and placed in a special viral culture tube. If the lesion has crusts, they are removed or punctured before swabbing. The viral culture tube must be kept in ice and sent to the laboratory as soon as possible.

Bacterial cultures may be collected with a sterile swab or wound culture kit. Box 53-1 gives specific instructions.

Skin Biopsy

A skin biopsy is indicated for deeper infections, suspicious lesions, or for evaluation of current treatment. A biopsy is an excision of a small piece of tissue for microscopic examination. Three common types of skin biopsies are punch, shave, and incisional.

A punch biopsy uses a small round cutting instrument, called a punch, to cut a cylinder-shaped plug of tissue for a full-thickness specimen. A shave biopsy removes just the area that has risen above the rest of the skin. An incisional biopsy is performed with a scalpel to make a deep incision and almost always requires sutures for closure. For all biopsies, explain the procedure, assist in preparing a sterile field, calm and comfort the patient during the procedure, and assist in dressing the site following the procedure. The most uncomfortable part of the procedure is usually the injection of the local anesthetic. Explaining the procedure and calming the patient can make the procedure less traumatic.

Other Diagnostic Tests

Wood’s Light Examination

Wood’s light examination involves the use of UV rays to detect fluorescent materials in the skin and hair present in certain diseases such as tinea capitis (ringworm). This examination is performed with a handheld black light in a darkened room.

Skin Testing

Patch and scratch tests are performed when allergic contact dermatitis is suspected. These are usually done by a dermatologist on uninvolved skin, such as the upper back or arms. Any hair in the area must first be shaved.

For the scratch test, the skin is superficially scratched or pricked with an allergen for an immediate reaction. If a reaction such as a wheal occurs, the test is positive for that allergen. Resuscitation equipment should be in the immediate vicinity in the event of a severe allergic (anaphylactic) reaction.

With the patch test, allergens are applied under occlusive tape patches; a delayed hypersensitivity reaction develops in 48 to 96 hours. For this test, the skin should be free of oils to promote patch adhesion, so cleanse the skin first with alcohol. The test site must remain dry and free from moisture. The patch is removed in 2 days. Any reaction is noted, with a final reading in 2 to 5 days.

THERAPEUTIC MEASURES FOR THE INTEGUMENTARY SYSTEM

Open Wet Dressings

Wet compresses may be ordered for acute, weeping, crusted, inflamed, or ulcerated lesions. The purpose of wet dressings is to decrease inflammation, cleanse and dry a wound, and promote drainage of infected areas. They may be ordered either sterile or clean, depending on the risk for infection. The solutions commonly consist of room temperature to cool tap water or normal saline solution, aluminum acetate solution (Burow’s solution), or magnesium sulphate. The dressing is saturated with the solution before it is applied. Wet dressings usually are applied every 3 to 4 hours for 15 to 30 minutes.

Wet dressings should not be prescribed for more than 72 hours because the skin may become too dry or macerated. If cool compresses are used, they should be reapplied every 5 to 10 minutes because they become too warm from body heat. If warm compresses are used, monitor the skin closely to prevent burns.
NURSING CARE TIP
To prevent chilling, no more than one-third of the body should be treated with a wet dressing at one time. Keep the patient warm during wet dressing treatment.

Balneotherapy
Balneotherapy (therapeutic bath) is useful in applying medications to large areas of the skin, as well as for débridement, or removing old crusts; for removing old medications; and to relieve itching and inflammation. The temperature of the water should be kept at a comfortable level, avoiding hot baths. The bath should last for 15 to 30 minutes, while maintaining its warmth. Fill the tub half full. Keep the room warm to minimize chilling. Advise the patient to wear loose clothing after the bath.

Water and saline solution are utilized for weeping, oozing, and erythematous lesions. Colloidal baths (such as oatmeal or Aveeno) are used for widely distributed skin lesions, for drying, and for relief of itching. Medicated tar baths, such as Almar-Tar or Balnetar, are used for chronic eczema and psoriasis. Any loose skin crusts can be remov ed after the bath. The room should be well ventilated because tars are volatile.

To increase hydration after the bath, a lubricating agent is applied to damp skin if prescribed. Bath oils, such as Alpha-Keri and Lubath, are used for lubrication and to relieve itching.

Gels, or semisolid emulsions, become liquid with topical application. They are usually greaseless and do not stain. Many topical steroids are prescribed in this manner.

Pastes are semisolid substances comprising ointments and powders. They are used for inflammatory disorders. Mineral oil can facilitate removal of pastes.

Topical Medications
Many types of topical medications are used to treat skin conditions. These include lotions, ointments and creams, powders, gels, pastes, and intralesional therapy. Systemic medications may be given for more serious conditions.

Lotions tend to cool the skin through water evaporation. They also may have a protective effect and may be antipruritic (anti-itch). Lotions are usually applied with cotton, gauze, gloves, or a soft brush.

Ointments and creams have a varied base (greasy, non-greasy, or penetrating), depending on the drug applied. These medications can protect the skin, provide lubrication, and prevent water loss. They are used for localized or chronic skin conditions. Ointments and creams can cause some reduction in blood flow to the skin. They are applied with a gloved hand or wooden tongue depressor.

Powders usually have a zinc oxide, talc, or cornstarch base and are used to absorb moisture and reduce friction. Powders are usually applied with a shaker top. Avoid use of powders in patients with respiratory disease or tracheostomies.

NURSING CARE TIP
Avoid applying too much powder in skinfold areas. Dermatitis can occur with too much powder in these areas. Products with a cornstarch base can provide a good medium for growth of microorganisms.

A bath mat should be used for treatment baths because some of the treatments may make the tub slippery.

Topical Medications
Mr. Evans comes to the doctor’s office with atrophic skin (thin, shiny, pink, with visible vessels) at the area of psoriasis where he is applying his corticosteroid ointment. He says that he has been applying a thick layer of ointment four times a day.

1. What should you teach Mr. Evans about his treatment?
2. What should you include when you document his skin condition?

Suggested answers are at the end of the chapter.

Dressings
Dressings may be used to enhance absorption of topical medications, promote retention of moisture, prevent evaporation of medication, and reduce pain and itching. Occlusive
dressing (for sealing a wound) are commonly used for skin disorders. For an occlusive dressing, an airtight plastic film is applied directly over the topical agent. Corticosteroids are also available in a special plastic surgical tape that can be cut to size. See the “Nursing Care Plan for the Patient With an Occlusive Dressing.”

Proper application of a plastic wrap dressing includes washing the area, lightly patting it dry, applying the medication to moist skin, covering the medicated area with plastic wrap, and covering with a dressing to seal the edges. Wet dressings and ointments should only be applied to affected areas, not to healthy intact skin, because this can cause maceration of good skin. Plastic wrap dressings should be used for no more than 12 hours a day.

Hydrocolloid dressings (e.g., DuoDERM, Tegasorb THIN) can help protect areas exposed to pressure and treat pressure ulcers in early stages. Gels, pastes, and granules can be used to fill in deep wounds to promote granulation and aid healing. See Chapter 54 for dressings used specifically for pressure ulcers. Skin tears should be covered with a nonadherent dressing such as Xeroform and wrapped with gauze. Table 53.3 summarizes various types of wound dressings.

Other items commonly used with topical treatments for skin conditions include gauze or cotton cloth held in place with:

- Small, stretchable tubular material (e.g., Surgitube, tube gauze) for fingers, toes, and extremities
- Disposable polyethylene gloves sealed at the wrist for hands
- Disposable diapers or cotton diapers for the groin and perineal areas
- Cotton cloth held in place with dress shields for the axillae
- Cotton or light flannel pajamas for the trunk
- A shower cap for the scalp
- A facemask made from gauze and stretchable dressings with holes cut out for eyes, nose, mouth, and ears.

The patient’s HCP or a wound care specialist should specify the type of dressing and particular materials needed.

### TABLE 53.3 COMMON DRESSINGS

<table>
<thead>
<tr>

**NURSING CARE PLAN for the Patient With an Occlusive Dressing**

**Nursing Diagnosis:** Impaired Skin Integrity related to open lesions

**Expected Outcome:** The patient will experience improved skin integrity as evidenced by reduction in size of lesion.

**Evaluation of Outcome:** Is there a decrease in wound size?

**Intervention** Assess areas of lesions for changes in size, color, swelling, and drainage three times a day or as ordered. **Rationale** Areas of redness, swelling, pain, and drainage may indicate infection. **Evaluation** Are lesions free of redness, swelling, pain, and drainage?

**Intervention** Assess lesions for presence or absence of dead tissue and exudates. **Rationale** Appearance indicates areas of healing and infection. **Evaluation** Are lesions free of exudates and dead tissue?

**Intervention** Cleanse wound as prescribed. Lightly pat dry. **Rationale** Cleansing helps provide a healthy granulation area for healing. **Evaluation** Is wound clean and free of debris, crusts, and exudate?

**Intervention** Apply prescribed topical agent to moist skin as ordered. Apply sparingly or as directed. **Rationale** Depends on agent and reason prescribed. **Evaluation** Does area exhibit signs of healing (e.g., decrease in size and numbers of lesions, free from infection, less itching)?

**Intervention** Cut plastic film to size and apply. Cover with an appropriate dressing to seal edges. **Rationale** Film enhances absorption of medication and helps retain moisture. **Evaluation** Is the topical agent adherent to the skin?

**Intervention** Remove dressing for 12 of 24 hours. **Rationale** Continued use may cause skin atrophy, folliculitis, erythema, and systemic absorption of medication. **Evaluation** Are there signs of healthy granulation tissue? Is skin pink? Are there fewer open areas? Is dressing removed for at least 12 hours every 24 hours?

**Nursing Diagnosis:** Disturbed Body Image related to presence of lesions or wound

**Expected Outcomes:** The patient will verbalize acceptance of condition. The patient will be willing to participate in care of lesion or wound.

**Evaluation of Outcomes:** Does patient verbalize acceptance of condition? Does patient participate in care of lesions?

**Intervention** Assess patient’s feelings regarding condition. **Rationale** Assessment provides a baseline for care. If patient denies condition, he or she may not comply with care. **Evaluation** Does patient state willingness to follow care instructions?

**Intervention** Care for patient with an accepting attitude. **Rationale** Patient will be aware of nuances in nurse’s behavior. **Evaluation** Does patient allow nurse to partake in care of lesion or wound?

**Intervention** Allow opportunities for patient to verbalize concerns about condition. **Rationale** Verbalization allows patient to begin to accept changes and problem solve. **Evaluation** Does patient verbalize feelings appropriately?

**Intervention** Provide referrals to support groups and counselors as appropriate. **Rationale** Patient may benefit from talking to others with similar condition or to another professional for objective evaluation. **Evaluation** Is patient receptive to appropriate referrals?

**Intervention** Assist patient in concealing lesion or wound in a safe and appropriate manner. **Rationale** Long sleeves and long pants may help conceal and protect lesions, and prevent further skin damage. **Evaluation** Is patient accepting of appearance of lesions? Are lesions or wounds visible?

*Continued*
Nursing Diagnosis: Self-Care Deficit: Bathing/Hygiene related to presence of lesions or wound and discomfort

Expected Outcomes: The patient will verbalize the importance of good hygiene. The patient will participate in bathing/hygiene.

Evaluation of Outcomes: Does patient verbalize importance of good hygiene? Is patient’s skin clean and dry?

Intervention: Assess patient’s level of hygiene. Rationale: Assessment provides a baseline for care. Evaluation: Is patient’s level of hygiene at an acceptable level?

Intervention: Instruct patient in appropriate bathing/hygiene: • Avoid strong detergents and soaps; use gentle emollient soaps or prescribed soaps. • Gently stroke areas of lesions. • Pat dry; avoid friction. • Maintain a little moisture on skin. • Maintain comfortable environmental temperature. • Have temperature of bath at a comfortable level to patient but not too hot. Rationale: Patient needs to be able to properly cleanse lesions to prevent infection. Avoidance of friction and strong soaps prevents further trauma to skin. Patient will not shiver in comfortable temperatures. Evaluation: Does patient demonstrate good bathing techniques? Are lesions free of infection?

SUGGESTED ANSWERS TO CRITICAL THINKING

1. Mr. Evans
   1. Teach Mr. Evans to apply the ointment in a thin layer and usually only twice daily (as ordered). He may be sensitive or allergic to the medication. Most likely, he is applying too much, too often.

2. Note the size (usually in centimeters), location, color, distribution, and configuration of lesions. Describe exactly what you see, avoiding judgments about what you think it is. Document any teaching you provided related to how his medication should be applied.

REVIEW QUESTIONS

1. When is the best time for the nurse to apply prescribed ointment to a patient with an inflamed skin rash?
   1. In the morning before the patient dresses
   2. When the patient will be resting for at least an hour
   3. After the patient bathes
   4. In the evening before bed

2. Which nursing interventions are essential to achieve maximum benefit for the patient receiving balneotherapy for widespread dermatitis? Select all that apply.
   1. Maintain the bath water at the hottest temperature tolerated by the patient.
   2. Keep the patient in the water for 15 to 30 minutes.
   3. Keep the tub room warm.
   4. Dry the skin vigorously following the bath.
   5. Use gentle or emollient soaps.

3. Which term should the nurse use to document a raised, fluid-filled lesion smaller than 1 cm?
   1. Macule
   2. Papule
   3. Vesicle
   4. Wheal
4. What equipment is most important to have readily available when a patient is undergoing skin testing for allergies?
   1. Resuscitation equipment
   2. Flashlight
   3. Measuring device
   4. Alcohol and cotton swabs

5. Which nursing intervention is essential to protecting the patient’s skin integrity when applying occlusive dressings?
   1. Make sure all skin surfaces are covered.
   2. Remove the dressings for 12 of every 24 hours.
   3. Apply a thick layer of prescribed ointment before applying the dressings.
   4. Apply a gauze dressing next to the skin, underneath the plastic film.

Answers can be found in Appendix C.
Nursing Care of Patients With Skin Disorders

KEY TERMS

- cellulitis (sel-yoo-LYE-tis)
- comedo (KOH-meh-doh)
- dermatitis (DER-mah-TYE-tiss)
- dermatomycosis (DER-mah-toh-mye-KOH-siss)
- eschar (ESS-kar)
- lichenified (lye-KEN-i-fye)
- onychomycosis (ON-ih-koh-my-KOH-siss)
- pediculosis (peh-DIK-yoo-LOH-siss)
- pemphigus (PEM-fih-guss)
- pruritus (proo-RYE-tuss)
- psoriasis (suh-RYE-ah-siss)
- purulent (PURE-you-lent)
- pyoderma (PYE-oh-DER-mah)
- seborrhea (SEB-uh-REE-ah)

LEARNING OUTCOMES

1. Explain the pathophysiology of each of the skin disorders listed in this chapter.
2. Describe the etiologies, signs, and symptoms of each of the skin disorders.
3. Describe current therapeutic measures that are used for each of the skin disorders.
4. List data to collect when caring for patients with disorders of the integumentary system.
5. Plan nursing care for patients with each of the skin disorders.
6. Explain how you will know if your nursing interventions have been effective.
Chapter 54  Nursing Care of Patients With Skin Disorders  1289

Skin disorders cover a wide array of diseases and conditions. They can be generalized or localized, acute, chronic, or traumatic. This chapter discusses common skin disorders encountered by nurses. An excellent resource on skin disorders is available at www.nlm.nih.gov/medlineplus/skinconditions.html. The American Academy of Dermatology can be accessed at www.aad.org.

PRESSURE ULCERS

Pathophysiology and Etiology

Patients often refer to pressure ulcers with old terms such as bedsores, decubitus ulcers, or pressure sores. Essentially, a pressure ulcer is a lesion caused by prolonged pressure against the skin. This may result from spending a prolonged period in one position, causing the weight of the body to compress the capillaries against a bed or chair, especially over bony prominences. Pressure ulcers are the result of tissue anoxia and begin to develop within 20 to 40 minutes of unrelied pressure on the skin. Other causes include pressure from a tight splint or cast, traction, or other device. Those at risk are immobile patients, those with decreased circulation, and those with impaired sensory perception or neurologic function.

Mechanical forces (pressure, friction, and shear) lead to the formation of pressure ulcers. The pressure level that closes capillaries in healthy people is 25 to 32 mm Hg. When pressure applied to the skin is greater than the pressure in the capillary bed, the blood supply to the tissues is decreased, which impairs cellular metabolism. This eventually causes tissue ischemia. This reduction in blood flow causes the skin to blanch, or lose color. The longer the pressure lasts, the greater the risk of skin breakdown and the development of a pressure ulcer.

Friction is the rubbing of the skin surface with an external mechanical force. Also referred to as “sheet burns,” this can happen when the patient is dragged or pulled across bed linens instead of being lifted.

Shearing occurs when the patient slides down in bed when the head of the bed is raised, or when being pulled or repositioned without being lifted off the sheets. With shearing, the skin and subcutaneous tissue remain stationary, and the fat, muscle, and bone shift in the direction of body movement. As a result, damage occurs deep within the tissues.

Any patient experiencing prolonged pressure is at risk for a pressure ulcer. Older adult patients have increased risk because of normal aging changes of the skin. Because thin patients have little padding when pressure is present, they have the greatest pressure applied to their capillaries. Obesity also is a contributing factor because adipose tissue is poorly vascularized and is therefore more likely to develop ischemic changes. Impaired peripheral circulation also makes the skin more susceptible to ischemic damage. See Chapter 24 for more information on problems caused by poor circulation.

Prevention

There are many interventions for the prevention of pressure ulcers (see “Evidence-Based Practice”).

USE A VALIDATED ASSESSMENT TOOL. Use an assessment tool such as the Braden or Norton scale to assess patients for physical condition, mental status, activity, mobility, and incontinence to determine the risk for pressure ulcers. Advanced age, low diastolic blood pressure, elevated body temperature, and inadequate current intake of protein are all risk factors associated with the development of pressure ulcers. See Table 54.1 for the Braden instrument.

CLEANSE THE SKIN. Gently cleanse the skin daily with tepid water and mild soap to prevent drying. To reduce friction, pat the skin dry rather than rubbing it dry. After bathing, daily lifelong lubrication of the skin with moisturizers is important to prevent dryness. Thoroughly dry skin-to-skin surfaces, such as under the breasts, skinfolds (especially in the groin and abdominal folds), and between the toes, to prevent prolonged exposure to moisture.

PREVENT DAMAGE FROM INCONTINENCE. If incontinence is a problem, clean the skin promptly with tepid water and mild soap, pat dry, and apply a moisture barrier to prevent breakdown.

AVOID MASSAGING BONY PROMINENCES. Avoid massaging bony prominences or reddened skin areas; blood vessels are damaged by massage when ischemia is present or when they lie over a bone.

MAINTAIN MOBILITY. Maintain the highest possible level of mobility, as follows:

- Teach patients to shift their weight every 15 minutes if possible when lying or sitting.
- Provide frequent active or passive range-of-motion exercises, as well as turning according to a written repositioning schedule. If patients are on bedrest, turn and reposition them at least every 2 hours, but preferably more often because ischemia development begins after 20 to 40 minutes of pressure.
- When positioning patients on their side, place them at a 30-degree angle or less and not directly on the trochanter because this area is especially sensitive to pressure and can quickly break down. If patients are placed on the trochanter, they usually become restless and squirm around to get off the trochanter.
- If the patient is seated in a chair, repositioning every hour is important. A mobility program specific to the patient must be developed.

REDUCE PRESSURE, FRICTION, AND SHEAR DAMAGE. Avoid elevating the head of the bed more than 30 degrees to reduce pressure on the coccyx and friction and shear damage from sliding down in the bed. Use a sheet to lift and move patients; provide an overbed trapeze to assist patients to move themselves.

ELEVATE HEELS AND AVOID PRESSURE ON CALVES. Elevate heels off the bed with pillows placed lengthwise under the calf or with heel elevators. Take care so pressure is not applied on the calves from the pillows.

**PROTECT BONY PROMINENCES FROM PRESSURE.** Be sure also to protect the patient’s elbows, sacrum, scapulae, ears, and occipital area from pressure.

**PREVENT ISCHEMIA.** Avoid the use of donut-shaped cushions. They create a circle of pressure that cuts off the circulation to the surrounding tissue, promoting ischemia rather than preventing it.

**PROTECT SKIN CONTACT SURFACES.** Pad skin contact surfaces, especially bony prominences, so they do not press against each other. (For example, place a small pillow between the knees when the patient is in a side-lying position.)

**USE PRESSURE-REDUCING MATTRESSES AND CUSHIONS.** Provide an appropriate pressure-relieving or pressure-reducing mattress and chair cushion for immobile patients.

**PREVENT MALNUTRITION AND DEHYDRATION.** Prevent malnutrition and dehydration by ensuring an adequate intake of protein, calories, and fluid; provide 2500 mL of fluid each day if not contraindicated by other medical problems.

“Gerontological Issues” summarizes additional preventive measures.

**Signs and Symptoms**

A developing pressure ulcer begins with a reddened area, usually over a bony prominence, that does not blanch with pressure. You have learned to check for capillary refill by pressing on a fingertip and watching it turn white, then red.
Chapter 54
Nursing Care of Patients With Skin Disorders

• Keep fingernails short to avoid scratching.
• Use pillows and pads to help maintain alignment with position changes. Use specialized mattresses and chair cushions designed to decrease pressure. Keep the patient’s heels off the bed with pillows under the calves for support and to prevent pressure.
• Encourage the older adult to be out of bed and active throughout the day. Remember to assess skin and reposition frequently even when out of bed because areas of pressure occur whether the patient is in or out of bed.
• Provide a high-protein, vitamin-rich diet if not contraindicated.
• Assess for dehydration and encourage fluids if not contraindicated.
• Make sure bed linens are kept dry and unwrinkled.

EVIDENCE-BASED PRACTICE

Clinical Question
What are best practices for preventing pressure ulcers?

Evidence
Researchers at both the Joanna Briggs Institute and the Agency for Research and Quality evaluated studies to determine which interventions are most effective for preventing pressure ulcers. Recommendations for assessment include regular skin inspection and use of the Braden Scale (Table 54.1) to predict pressure ulcer risk. Interventions to reduce pressure ulcer risk include good skin care with warm (not hot) water and use of lotion after bathing, avoidance of massage over bony prominences, protection of skin from incontinence or other body fluids with barrier products, individualized repositioning schedules based on patient condition, and use of pressure reducing devices or mattresses.

For at-risk patients, follow nutritional guidelines for hydration (1 ml/kcal of fluid per day) and calories (30–35 kcal/kg of body weight per day), protein (1.25–1.5 g/kg per day). Give high-protein supplements or tube feedings in addition to the usual diet in persons at nutritional and pressure ulcer risk (Agency for Health Care Research and Quality, 2013).

Implications for Nursing Practice
Use a valid risk assessment tool such as the Braden Scale according to agency policy. Use a pressure-reducing mattress and administer oral nutritional supplements and fluids to the at-risk patient (Braden Scale score 18 or less). Keep skin clean and dry and reposition the patient frequently. See www.guideline.gov/content.aspx?id=43935 for additional recommendations.

REFERENCE

NURSING CARE TIP
Implement all preventive measures possible, and be sure to document with photographs all pressure ulcers present on admission to the hospital. Pressure ulcers are classified as serious reportable events because they can be prevented, and therefore hospitals will not be paid by Medicare for care of stage III, IV, or unstageable pressure ulcer acquired during hospitalization.

again. If redness returns within 3 seconds, then capillary refill is considered to be adequate. A pressure ulcer stays red and does not blister. If pressure is not relieved and healing does not occur, it can progress to an open, ulcerated area. Stages of ulcers are discussed in the section on data collection.

The most common sites for pressure ulcers are the sacrum, heels, elbows, lateral malleoli, greater trochanters, ischial tuberosities, base of the skull, scapulae, and ears. Most patients experience pain at the ulcer site. A report of pain requires continual monitoring, documentation, and treatment.

LEARNING TIP
Pressure ulcers may be described according to a three-color system:

- Black wounds indicate tissue necrosis.
- Yellow wounds have slough, which is a layer of dead tissue surrounding living tissue. It is usually yellow, creamy, or tan in color. It may have exudate and may be infected.
- Red wounds are pink or red and are in the healing stage.
A wound may contain a mixture of black, yellow, and red colors. Necrotic wounds are the worst because they contain dead tissue. Beefy red wounds are desired because they are healing wounds. It is important to consider treating the worst color present first, or healing will be delayed. For example, if a wound is both yellow and black, the dead tissue must be removed first before the infection can be effectively treated. This color system is a helpful system for patients and families to use to describe wounds to the home care nurse because colors are easily recognized and understood by most people.

**Complications**

Wound infection is a common complication. New ulcers can also appear, and the present ulcer can progress to a deeper wound. Some wounds take a prolonged time to heal or never heal.

**Diagnostic Tests**

All open pressure ulcers are considered to be colonized with bacteria. This means that bacteria are present, but the wound is not necessarily infected. In most cases, adequate cleansing and débridement can prevent bacterial colonization from advancing to clinical infection. Swab cultures and culture and sensitivity tests may be done to identify the causative organism in suspected infection sites. (See Chapter 53 for instructions for obtaining a culture.) Results need to be interpreted to distinguish between true wound infection and bacterial colonization. If the wound is healing by secondary intention, it becomes colonized by bacterial flora from the skin and from the environment. If, however, the wound is extensive, bacterial growth may exceed the defenses of the local tissue, and a true wound infection will result.

If the wound does not show signs of healing or if an ischemic ulcer is suspected, noninvasive (such as Doppler studies) or invasive (such as arteriogram) arterial blood supply studies are recommended. Biopsies may be performed for large, extensive unhealing wounds to be sure a cancer is not a complicating factor.

**Therapeutic Measures**

Treatment varies according to the size, depth, and stage of the pressure ulcer; the special needs of the patient; and health care provider preference. All pressure must be removed from the affected area for healing to occur. Cleanliness must be maintained. Basic treatment includes débridement, cleansing, and dressing of the wound to provide a moist and healing environment.

### LEARNING TIP

The epidermis “skates” on moisture, so wounds must be kept moist to heal.

**Débridement**

Débridement is the removal of dead or nonviable tissue from a wound to help clean the wound and facilitate formation of granulation tissue. It may be done with or without surgery. Nonsurgical débridement includes mechanical, enzymatic, and autolytic methods. Surgical débridement is used only if the patient has sepsis or cellulitis or to remove extensive eschar. Eschar is a black or brown hard scab or dry crust, or thick, black, leather-like tissue that forms from necrotic tissue. It may hide the true depth of the wound and must be removed for the wound to heal.

**MECHANICAL DÉBRIDEMENT.** Scissors and forceps can be used for mechanical débridement to selectively remove nonviable tissue. Dextranomer beads, another method of mechanical débridement, can be sprinkled over the wound to absorb exudate and all other products of tissue breakdown, as well as surfactant bacteria. Whirlpool baths and wet-to-dry saline gauze dressings may also be used for mechanical débridement. For wet-to-dry dressings, the wet gauze is placed directly on the wound (avoiding surrounding healthy tissue) and allowed to dry completely. The drying process causes the gauze to adhere to the wound; when it is pulled off, tissue is pulled off with it. This results in nonselective débridement because viable tissue may also be removed in this process. These methods are painful, so the patient should be premedicated for pain and assessed often.

**ENZYMATIC DÉBRIDEMENT.** Enzymatic débridement involves application of a topical enzyme débriding agent. These agents vary as to application methods, so careful reading of instructions is necessary. Most débriding agents are proteolytic enzymes that selectively digest necrotic tissue. Be careful to apply them only to the wound and to avoid contact with healthy tissue.

**AUTOLYTIC DÉBRIDEMENT.** Autolytic débridement is the use of a synthetic dressing or moisture-retentive dressing over the ulcer. The eschar then self-digests via the action of the enzymes that are present in the fluid environment of the wound. This method is not used for infected wounds, because the infection would worsen.

**SURGICAL DÉBRIDEMENT.** Surgical débridement involves the removal of devitalized tissue, slough, or thick, adherent eschar with a scalpel, scissors, or other sharp instrument. Slough is loose, yellow to tan stringy necrotic tissue. Slough, like eschar, can be tightly adhered to the wound bed.

Depending on the amount of débridement to be done, this may be performed in the operating room, a treatment room, or the patient’s room. Following surgical débridement, grafting may be required to close the wound. This becomes necessary if it is a full-thickness ulcer, if there is loss of joint function, or for cosmetic purposes. For procedures performed without anesthesia, be sure to premedicate the patient for pain. Continually monitor for pain during the procedure, especially if there is a donor site for grafting.
**Wound Cleansing**

The ulcer should be thoroughly cleansed using a whirlpool, a handheld showerhead, or an irrigating system with a pressure between 4 and 15 pounds per square inch (psi). A 30-mL syringe with an 18-gauge needle works well for this purpose. Pressure less than 4 psi does not adequately cleanse the wound, and pressure greater than 15 psi may damage tissue. If an irrigating system is used, 250 mL of normal saline solution (or sometimes tap water for home care) should be used to thoroughly cleanse the wound. If the wound is red, gentle irrigation with a needleless 30- to 60-mL syringe should be used to prevent trauma and bleeding. However, if the wound has been diagnosed as being infected, flushing with a 30- to 60-mL syringe and an 18-gauge needle provides the pressure needed to help remove bacteria.

**LEARNING TIP**

* Dilution is the solution to wound pollution!

Once the wound has been cleansed and débrided, apply a dressing. Wounds heal more rapidly in a moist environment, with minimal bacterial colonization and a healing temperature. This takes 12 hours to occur after the wound is covered with an occlusive dressing. If a dressing is frequently removed, the wound may not reach its healing temperature, and healing may be impaired. When possible, the dressing should be left in place for extended periods. Draining wounds may require frequent dressing changes.

**Wound Dressings**

Dressings vary according to size, location, depth, stage of ulcer, and preference of the ordering practitioner. Commonly used dressing materials include hydrogel dressings, polyurethane films, hydrocolloid wafers, biological dressings, alginates, and cotton gauze. See Chapter 53 for more information on dressing types. The use of an appropriate dressing promotes an optimum healing environment. Hypoallergenic tape should be used to secure dressings if tape is necessary. Protective paste may be applied to protect unaffected tissue from topical agents. In all cases, pressure should be kept off the wound. No treatment will be effective if pressure continues to damage the tissue.

**Negative Pressure Wound Therapy**

Negative pressure wound therapy (NPWT) may be effective for healing large open pressure ulcers (Fig. 54.1). In NPWT, a wound is packed loosely with a sterile sponge and then covered with an occlusive dressing. A vacuum source is placed in the wound, and gentle negative pressure is applied. The negative pressure allows excess drainage and infectious material to be removed, which reduces pressure on delicate new tissue. With small vessels decompressed, circulation is increased, and healing is accelerated. NPWT also maintains a moist environment for optimal healing. Evidence strongly supports NPWT for nonischemic diabetic foot ulcers; it is also effective for pressure ulcers and other deep wounds (Vig et al, 2011). Risks of NPWT include bleeding in patients at risk, such as those on anticoagulant therapy.

**Other Therapies**

Much research is ongoing in the field of wound healing. Some success has been shown with the following therapies: biological or biological skin equivalent dressings, collagen application, platelet-rich plasma application, platelet-derived growth factor application, silver-based products, hyperbaric oxygen therapy, and ozone-oxygen treatments.
Nursing Process for the Patient With a Pressure Ulcer

Data Collection

Collaborate with the registered nurse (RN) to evaluate the status of the pressure ulcer often, as well as underlying causes and barriers to healing. Monitor for risk factors for impaired healing, such as prolonged immobility, incontinence, and inadequate nutrition and hydration. Also monitor intact skin to prevent development of new pressure ulcers.

Use transparency film or a disposable ruler to measure the diameter of the ulcer in centimeters. Imagine a clock superimposed over the wound with 12 o’clock at the head and 6 o’clock at the feet. Measure in centimeters from 12 to 6 o’clock, and from 9 to 3 o’clock. Depth can be measured with a cotton-tipped applicator. Also, gently probe a cotton-tipped applicator under the skin edges to detect tunneling and measure lateral tissue destruction.

Several staging systems are available for pressure ulcers based on the depth of tissue destruction. Most staging systems categorize wounds from stage I to stage IV. Additional categories may include deep tissue injury and unstageable (Fig. 54.2).

- **Deep tissue injury:** The National Pressure Ulcer Advisory Panel (NPUAP, 2007) defines deep tissue injury as a “purple or maroon localized area of discolored intact skin or blood-filled blister due to damage of underlying soft tissue from pressure and/or shear. The area may be preceded by tissue that is painful, firm, mushy, boggy, warmer, or cooler as compared to adjacent tissue.” Deep tissue injury is considered unstageable because it is impossible to determine how deep the tissue damage is. This stage can progress quickly to a stage III or IV ulcer, even with appropriate treatment.
- **Stage I:** The skin is still intact, but the area is red and does not blanch when pressed. There may also be warmth, hardness, and discoloration of the skin. A stage I ulcer may be difficult to detect on a dark-skinned person.
- **Stage II:** There is a break in the skin, with partial-thickness skin loss of epidermis, dermis, or both. The ulcer may appear as an abrasion, a shallow crater, or a blister. Stage II ulcers do not contain slough (yellow fibrous tissue).
- **Stage III:** There is full-thickness skin loss, which extends to the subcutaneous fat but not to the fascia. The ulcer looks like a deep crater and may have undermining of adjacent tissue. Bone, tendon, and muscle are not visible.
- **Stage IV:** There is full-thickness skin loss with exposed muscle, bone, or support structures such as tendons. Slough or eschar may be present. There may be undermining and sinus tracts (tunneling).
- **Unstageable:** The base of the ulcer is covered by slough or eschar so that the depth cannot be evaluated. The wound bed must be debrided before staging and treatment can take place. One exception, according to NPUAP (2007), is stable, dry, intact eschar on the heels. It serves as the body’s natural (biological) cover and should not be removed.

Observe wound exudate. Two common types of wound exudate are serosanguineous and purulent. Serosanguineous exudate is fluid consisting of serum and blood. It is blood-tinted, amber-colored fluid. Purulent fluid is a fluid that contains pus. It can vary in color and have different odors, depending on which bacteria are present. Creamy yellow pus may indicate *Staphylococcus*. Beige pus that has a fishy odor may suggest *Proteus*. Green-blue pus with a fruity odor may indicate *Pseudomonas*. Brown pus with a fecal odor may suggest *Bacteroides*. The wound must be cultured to accurately identify bacteria.

Gently palpate the wound with a gloved hand to determine the texture of granulations. Granulation tissue has a budding appearance from the development of tiny new capillaries. If the granulations are healthy, they have a slightly spongy texture.

Document all findings carefully in the medical record, so all health team members can monitor progress of healing. Many institutions have specific forms for drawing pictures of the locations and sizes of wounds and for photographs to monitor the healing process. Follow policy at the institution where you work.

Nursing Diagnoses, Planning, Implementation, and Evaluation

See the “Nursing Care Plan for the Patient With a Pressure Ulcer.”

FIGURE 54.2 Stages of pressure ulcers include deep tissue injury, stages I through IV, shown here, and unstageable, as described in the text. From Dillon, P. M. (2007). *Nursing health assessment* (2nd ed.). Philadelphia: F.A. Davis, p. 239, with permission.
Chapter 54  Nursing Care of Patients With Skin Disorders  1297

NURSING CARE PLAN for the Patient With a Pressure Ulcer

**Nursing Diagnosis:** Impaired Skin Integrity related to pressure on skin surface, reduced circulation, or immobility

**Expected Outcomes:** The patient’s skin integrity will be improved as evidenced by decrease in wound size and depth, no development of additional pressure ulcers.

**Evaluation of Outcomes:** Is there a decrease in wound size? Are there any new pressure ulcers?

**Intervention** Monitor status of pressure ulcer according to stage, color, exudate, texture, size, and depth.  
**Rationale** Provides data on which care is based.  
**Evaluation** What stage is ulcer? Is it improving or worsening?

**Intervention** Determine and remove cause of pressure (e.g., immobility, friction, shearing).  
**Rationale** Allows for correction and also prevents further trauma.  
**Evaluation** What is the cause of the ulcer? Is cause removed?

**Intervention** Cleanse wound gently with warm water; rinse; pat dry gently with gauze. Do not rub the area.  
**Rationale** Reduces number of bacteria. Drying prevents maceration of skin. Gentle handling prevents further trauma.  
**Evaluation** Is wound clean and dry?

**Intervention** Débride or assist with débridement of wound as prescribed (method depends on patient’s condition and goals of care).  
**Rationale** Débridement removes drainage and wound debris. Permits granulation of tissue.  
**Evaluation** Does wound look clean and free of debris?

**Intervention** Apply topical agents and/or dress wound as prescribed. Make sure dressing stays intact with movement and edges do not roll, causing more pressure.  
**Rationale** Protects underlying wound and helps promote healing.  
**Evaluation** Is dressing applied appropriately?

**Intervention** Position patient off the ulcer.  
**Rationale** Prevents further pressure and trauma on ulcer.  
**Evaluation** Is patient positioned off the ulcer?

**Intervention** If a leg ulcer, provide for frequent rest periods with leg elevated; if immobile, reposition every 2 hours.  
**Rationale** Prevents further tissue breakdown.  
**Evaluation** Is leg elevated? Is patient repositioned every 2 hours?

**Nursing Diagnosis:** Risk for Infection related to open wound

**Expected Outcomes:** The patient will not experience wound infection or systemic sepsis as evidenced by clean wound bed and by temperature and white blood cell count within normal limits. (Total elimination of bacteria is impossible because of the nature of the condition.)

**Evaluation of Outcomes:** Is patient free from signs and symptoms of local and systemic infection?

**Intervention** Examine ulcer at every dressing change. Check for areas of tenderness, swelling, redness, heat, and drainage. Report changes.  
**Rationale** Allows for early recognition of infection and response to treatment.  
**Evaluation** Are signs of infection present? Are they reported promptly?

**Intervention** Monitor temperature at least every 12 hours.  
**Rationale** Elevated body temperature is one sign of infection.  
**Evaluation** Is patient afebrile?

**Intervention** Provide meticulous wound care (see Impaired Skin Integrity).  
**Rationale** Helps decrease the level of contamination and prevent infection.  
**Evaluation** Is wound showing signs of healing without purulent drainage?

**Intervention** Use thorough hand hygiene techniques. Use sterile technique for dressing changes.  
**Rationale** Prevents cross-contamination.  
**Evaluation** Does nurse take proper precautions?

Continued
NURSING CARE PLAN for the Patient With a Pressure Ulcer—cont’d

**Nursing Diagnosis:** Pain related to ulcer and treatments as evidenced by pain rating on 0-to-10 scale

**Expected Outcomes:** The patient will be as comfortable and as pain free as possible as evidenced by statement of decreased pain and ability to sleep at night.

**Evaluation of Outcomes:** Does patient express comfort? Does patient express a decrease in pain? Is patient able to sleep?

**Intervention** Assess level of pain with pain scale and by observing facial expressions and positioning of body. **Rationale** Monitors level of pain and response to therapy. **Evaluation** At what level is pain? Is it better or worse with treatment?

**Intervention** Offer analgesics as prescribed. Request order for topical analgesics as needed with dressing changes and cleaning of the wound. **Rationale** Analgesics help relieve pain. **Evaluation** Are analgesics effective?

**Intervention** Decrease anxiety with relaxation techniques (e.g., distraction, music). **Rationale** Relaxation can lessen pain intensity. **Evaluation** Is patient less anxious? Does patient verbalize less pain?

**Intervention** Maintain a comfortable environment: provide for privacy; position in good alignment and comfortably; and maintain a comfortable room temperature. **Rationale** Relaxes patient and lessens intensity of discomfort. **Evaluation** Does patient express an increase in comfort?

**INFLAMMATORY SKIN DISORDERS**

**Dermatitis**

**Pathophysiology and Etiology**

Dermatitis is inflammation of the skin and is characterized by itching, redness, and skin lesions, with varying borders and distribution patterns. There are three common types of dermatitis: contact dermatitis, atopic dermatitis, and seborrheic dermatitis. Contact dermatitis is caused by exposure to an allergen or irritant such as soap, perfume, or poison ivy. Atopic dermatitis tends to be hereditary and is associated with allergies, asthma, and hay fever. Seborrheic dermatitis occurs most often on the scalp, usually in individuals with oily skin. All types tend to be chronic and respond well to treatment but are prone to recur. See Table 54.2 for common types of dermatitis.

**Prevention**

The patient should prevent irritation to the skin by avoiding irritants, allergens, and excessive heat and dryness and by controlling perspiration. Baths should be short, in tepid water. Deodorant soaps should be avoided; mild superfatted soaps are recommended instead. Dry skin can be lubricated with creams, oils, or ointments as appropriate.

**NURSING CARE TIP**

Many institutions now have nurses who have been specially trained in wound care. Consult one of these nurses for expert wound assessment and treatment recommendations.

**CRITICAL THINKING**

**Mr. Russ**

Mr. Russ is an 84-year-old man who was admitted from home to the medical-surgical unit after a fall that fractured his femur. He has a history of type 2 diabetes. He had an open reduction and internal fixation of his femur and is now in a brace. He is 6 feet tall and weighs 160 pounds. His appetite is poor; his wife states he has lost 15 lb in the past 3 months. He is occasionally incontinent of urine.

1. How can you be vigilant in identifying risks and preventing skin breakdown in Mr. Russ?
2. What other members of the health team might you collaborate with when planning care for Mr. Russ?

*Suggested answers are at the end of the chapter.*

**WORD BUILDING**

<td>Irritant</td>
<td>Caused by direct contact with an irritating substance, such as soap, detergent, strong medication, astringent, cosmetic, or industrial chemical</td>
</tr>
<tr>
<td>Allergic</td>
<td>From contact with an allergen, such as perfume, tanning lotion, medication, hair dye, poison ivy, poison oak; contact results in cell-mediated immune response</td>
</tr>
<tr>
<td>Atopic</td>
<td>Chronic inherited condition; may be associated with respiratory allergies or asthma; can vary between bright red maculas, papules, oozing, and lichenified or hyperpigmented areas</td>
</tr>
<tr>
<td>Seborrheic</td>
<td>Chronic, inflammatory disease usually accompanied by scaling, itching, and inflammation; seborrhea is excessive production of sebaceous secretions; found in areas with abundant sebaceous glands (scalp, face, axilla, groin) and where there are folds of skin; can appear as dry, moist, or greasy scales, yellow or pink-yellow crusts, redness, and dry flakiness; can be associated with emotional stress; genetic predisposition may exist</td>
</tr>
</tbody>
</table>

**Itching and scratching should be prevented as much as possible.**

**Signs and Symptoms**

Itching and rashes or lesions are the main clinical manifestations of dermatitis. The lesions vary depending on the type and location of dermatitis. Rashes and lesions may present as dry, flaky scales, yellow crusts, redness, fissures, macules, papules, and vesicles. (These are described in Chapter 53.) Scratching can make any of these lesions worse.

**Complications**

The lesion or rash worsens with continued irritation, exposure to offending agents, or scratching. Infections of the skin are common and may be due to the many open areas and breaks in the skin, as well as the patient’s reluctance to properly wash the affected area because of pain from the lesions. Some infections can also become systemic.

**Diagnostic Tests**

Diagnosis is usually based on history, symptoms, and clinical findings. If infection is suspected, cultures of the lesions may be ordered to identify the infecting agent.

**Therapeutic Measures**

Treatment varies according to symptoms. Basic treatment objectives are to control itching, alleviate discomfort and pain, and prevent scratching.

**NURSING CARE TIP**

Itching and scratching can occur during sleep, causing the rash to worsen. Have the patient wear cotton gloves at night to prevent scratching. Oatmeal baths may also help.

**WORD BUILDING**

*lichenified: leichen—scaly growth + facere—to make
seborrhea: sebum—tallow + rhoia—flow*
Advise the patient to use a sunscreen agent when outdoors.

lightly patting dry, avoiding friction, and avoiding hot water.

dates, scales, and other wound debris, providing a clean area
vent further crust formation; the y also serve to loosen exu-
sious side effects, including adrenal suppression.

Steroids such as hydrocortisone or methylprednisolone may be used to suppress inflammation. They can be administered as topical, intralesional, or systemic agents. The specific type used depends on the type of lesion, the body area involved, and the extent of the lesion. Topical administration is preferred if possible because systemic steroids can cause serious side effects, including adrenal suppression.

Tub baths and wet dressings help control oozing and prevent further crust formation; they also serve to loosen exudates, scales, and other wound debris, providing a clean area for topical application of medication. Protect the skin by lightly patting dry, avoiding friction, and avoiding hot water. Advise the patient to use a sunscreen agent when outdoors.

**Nursing Process for the Patient With Dermatitis**

**DATA COLLECTION.** You can use the WHAT’S UP? format to assess the rash, as described in Chapter 53. Also refer to Chapter 53, Table 53.1, for specific questions to ask. Observe the rash or lesions for character, distribution, description, tenderness, signs of scratching, and other associated problems.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.**

**Impaired Skin Integrity related to rash, lesions, and scratching**

**EXPECTED OUTCOME:** The patient’s skin integrity will improve as evidenced by reduction in lesions and absence of signs or symptoms of infection.

- Monitor skin condition regularly to determine if treatment is working.
- Cleanse the area as ordered by health care provider (HCP), taking care not to irritate the skin further, to keep area clean and prevent infection.
- Provide cool moist compresses, dressings, or tepid tub baths to help relieve inflammation and itching, débride lesions, and soften crusts and scales.
- Pat the skin dry rather than rubbing to prevent further trauma.
- Apply topical agents as ordered to help suppress inflammation and itching.
- Provide skin care at bedtime to help promote comfortable sleep. Many antihistamines also have a sedative effect.
- Encourage patient to eat a high-protein diet to promote healing and replace lost protein. If lesions are generalized, protein can be lost through oozing of serum. Confirm appropriateness of high-protein diet with primary care provider.
- Encourage use of gloves or mitts, especially at night, to help prevent scratching.
- Advise the patient to keep fingernails short to prevent scratching.
- Teach the patient that application of slight pressure with a clean cloth may help relieve itching.

**EXPECTED OUTCOME:** The patient will verbalize concerns if they wish to do so. Talking about concerns may help the patient to begin to work through feelings about body image but should not be forced.

- Refer to a support group, if available, to receive support from others in similar circumstances.
- Display an accepting attitude while caring for skin lesions. The patient will be quick to pick up your reaction to the lesions, especially if it is negative.
- Encourage the patient to participate in skin care to allow more control over the situation.
- Encourage the patient to wear long sleeves or other appropriate covering if the patient desires to make the lesions less noticeable.

**Deficient Knowledge related to disease and treatment**

**EXPECTED OUTCOME:** The patient will verbalize understanding of the condition and demonstrate ability to perform self-care measures.

- Determine patient’s baseline knowledge of condition and treatment. Teaching should build on baseline understanding.
- Instruct the patient in application of topical agents and dressings. Overuse of medications can further traumatize skin; be sure to follow package or prescription directions.
- Instruct the patient in how to recognize changes, improvement, or flare-ups of the disorder and what symptoms to report to the health care provider. Because most skin conditions are cared for at home, it is important for the patient to have the skills needed to monitor the condition and carry out treatment appropriately.
- Advise the patient to avoid overexposure to sun and to use sunscreen agents when outdoors to prevent skin damage.
- Teach the patient measures to prevent future flare-ups if possible. Flare-ups may be avoided if the patient understands what triggers them.

**NURSING CARE TIP**

Teach patients that when applying topical medications, more is not better!

- **WORD • BUILDING •**
  - pruritis: prur—itch + itis—condition
EVALUATION. If medical and nursing care have been effective, the lesions will be controlled or in remission, the patient will state that itching and other discomforts are controlled, and the patient will be able to describe and demonstrate self-care measures.

**Psoriasis**

**Pathophysiology and Etiology**

Psoriasis is a chronic inflammatory skin disorder in which the epidermal cells proliferate abnormally fast. Usually, epidermal cells take about 27 days to shed. With psoriasis, the cells shed every 4 to 5 days. The abnormal keratin forms loosely adherent scales with dermal inflammation.

The exact cause is not known; however, it is autoimmune in nature, with T cells attacking healthy skin cells, causing an increase in skin cell, T-cell, and white cell production. Often there is a family history of psoriasis. The average age at onset is 27 years, although it can begin at any age. The condition can be severe if the onset is in childhood.

Psoriasis is characterized by exacerbations and remissions. Many factors influence the suppression and outbreak of lesions, which varies from individual to individual. Sun and humidity may suppress lesions. Aggravating factors include streptococcal pharyngitis, emotional upset, stress, hormonal changes, cold weather, skin trauma, smoking, alcohol, and certain drugs (e.g., antimalarial agents, lithium, beta blockers).

**Prevention**

Because the exact etiology is not known, measures to prevent exacerbation of symptoms are specific to the patient’s circumstances. General preventive measures include avoidance of upper respiratory infections, especially streptococcal infections; avoidance of or coping with emotional stress; avoidance of skin trauma, including sunburns; and avoidance of medications that can precipitate a flare-up.

**Signs and Symptoms**

Signs and symptoms vary according to the patient and the particular type of psoriasis. Lesions are red papules that join to form plaques with distinct borders (Fig. 54.3). Silvery scales develop on untreated lesions. Areas most often affected are the elbows and knees, scalp, umbilicus, and genitals. Other signs and symptoms include nail involvement, involvement in the gluteal fold (called intergluteal pinking), itching, and dry or brittle hair.

**Complications**

Because of the nature of the disease with its lesions and itching, secondary infections can occur. Psoriatic arthritis can develop after the psoriasis has developed, with nail changes and destructive arthritis of large joints, the spine, and interphalangeal joints. If the psoriasis becomes severe and widespread, fever, chills, increased cardiac output, and benign lymphadenopathy can result.

**Diagnostic Tests**

Testing depends on the severity of the psoriasis. Usually, diagnosis is based on physical assessment alone. Skin biopsy or other diagnostic tests may be performed to rule out concurrent disease or secondary infection.

**Therapeutic Measures**

Treatment varies according to the type and extent of the disease, as well as patient preference. Psoriasis is a chronic disease with remissions and exacerbations. Basic treatment objectives are to decrease the rapid epidermal proliferation, inflammation, and itching and scaling. The patient may be instructed to bathe daily in a tub, using a soft brush to assist in the removal of scales.

A variety of topical and systemic agents are used to treat psoriasis. Topical corticosteroids may be used for their anti-inflammatory effect. Occlusive dressings are commonly used to enhance penetration of medications (see Chapter 53). Keratolytic ointments or gels enhance the effects of salicylic acid to loosen or remove scales. Synthetic vitamin D cream slows the proliferation of skin cells. Fish oil supplements may reduce inflammation in some patients.

Tar preparations may be prescribed along with corticosteroids. The tar acts as an antimitotic, slowing the epidermal cell division. Occlusive dressings are not used with tars. Anthralin is a substance extracted from coal tar that suppresses mitotic activity. The anthralin may be mix ed with salicylic acid in a stiff paste. The patient must be closely observed because anthralin is a strong irritant and can cause chemical burns. It is usually applied for no longer than 2 hours. Both coal tar and anthralin are commonly used in combination with ultraviolet (UV) light and are usually administered in inpatient settings or specialized outpatient clinics.

**WORD BUILDING**

- **psoriasis:** psor—itch + iasis—inflammation
Topical preparations for the scalp are used in shampoo form. Teach the patient to read package instructions; these preparations generally need to be left in the hair for a period of time to work.

UV light may be designated as UVB, shorter wavelength, or UVA, longer wavelength. UVA is from an artificial source, such as special mercury vapor lamps. The amount of exposure depends on the patient’s condition, pigmentation, and susceptibility to burning. The patient must wear eye guards during treatments. Oral psoralen tablets (a photosensitizing agent) followed by exposure to UVA is called PUVA therapy. PUVA therapy temporarily inhibits DNA synthesis, which is antimitotic. Because psoralen is a photosensitizing agent, the patient must wear dark glasses not only during the treatment period but also for the entire day after a treatment. The long-term safety of PUVA therapy is still unknown. Possible side effects include increased skin carcinomas, premature skin aging, and actinic keratosis (premalignant lesions of the skin). The patient should be observed closely for redness, tenderness, edema, and eye changes. Initial and follow-up eye examinations, skin biopsies, urinalysis, and blood tests may be ordered.

Retinoids are oral agents such as acitretin (Soriatane) that promote skin cell differentiation and inhibit malignancies from forming in the skin. They may be used in combination with UV therapy.

Antimetabolites, usually used for cancer chemotherapy, are reserved for the most severe cases. Methotrexate is the most common agent given. Because of its hepatotoxicity, it is contraindicated in patients with liver disease, alcoholism, renal disease, and bone marrow suppression. Other systemic agents, such as cyclosporine and etanercept (Enbrel) work by altering the immune system.

Mrs. Long

Mrs. Long arrives at the health clinic stating that the shampoo prescribed for her scalp psoriasis is not working. She says that she washes her hair thoroughly with the medicated shampoo and then rinses completely. She wants to know why her scalp shows no signs of improvement.

1. What additional information should you collect?
2. What can you teach her?

Nursing Care

Nursing care for the patient with psoriasis is the same as nursing care for the patient with dermatitis. Teach the patient how to use prescribed medications and how to identify and avoid triggers. Explain that drinking alcohol can interfere with some treatments. In addition, consult with the physician about recommending small amounts of sunlight to help improve skin lesions.

Infectious Skin Disorders

A variety of infections can affect the skin. The most common disorders are discussed in this section. See Table 54.3 for a summary of additional skin infections.

**Table 54.3 Infectious Skin Disorders**

Herpes Simplex

Pathophysiology and Etiology

Herpes simplex virus (HSV) infection is a common viral infection that tends to recur repeatedly. There are two types of herpes simplex: that caused by type 1 virus (HSV-1), which occurs above the waist and causes a fever blister or cold sore (Fig. 54.4), and that caused by type 2 virus (HSV2), which occurs below the waist and causes genital herpes. See Chapter 44 for information on genital herpes.

The primary infection occurs through direct contact, respiratory droplet, or fluid exposure from another infected person. Following the initial infection, the virus lies dormant in nerve ganglia near the spinal column, where the immune system cannot destroy it. The patient is asymptomatic at this time.
Recurrence of symptomatic infection can happen spontaneously or may be triggered by stressors such as fever, sunburn, illness, menstruation, fatigue, or injury. The secondary lesion may appear isolated or as groups of small vesicles or pustules on an erythematous base. Crusts eventually form, and the lesions heal in about 1 week. The lesions are contagious for 2 to 4 days before dry crusts form.

**Prevention**
Avoidance of contact with a known infected lesion during the blistering phase can prevent the primary lesions. Patients should also be taught to avoid sharing contaminated items such as toothbrushes, lipsticks, and drinking glasses. This disease can recur spontaneously. Avoidance of stressors, such as sunburn, injury, and fatigue, may delay a recurrence. The use of sunscreens, especially on the lips, may be helpful.

**Signs and Symptoms**
Some patients may have a prodromal phase of burning or tingling at the site for a few hours before eruption. The area becomes erythematous and swollen. Vesicles and pustules erupt in 1 to 2 days. There may also be redness with no blistering. Lesions can burn, itch, and be painful. The attacks vary in frequency but diminish with age. The patient is contagious with each outbreak until scabs are formed.

**Complications**
If herpes simplex is present in the vagina at childbirth, the newborn may be infected (meningoencephalitis or a paravisceral infection may occur). If the person touches the affected area and then rubs the eyes, the eyes can become severely infected. Secondary bacterial infection of lesions can occur. Rarely, herpes encephalitis can occur. This is deadly if not treated promptly.

**Diagnostic Tests**
Cultures of the lesions provide a definitive diagnosis. Most lesions are diagnosed on the basis of history, signs, and symptoms.

**Therapeutic Measures**
There is no complete cure for herpes simplex. Recurrences will happen. Topical acyclovir (Zovirax) ointment is the drug of choice for primary lesions, to suppress the multiplication of vesicles. Docosanol (Abreva) is an over-the-counter topical antiviral agent that may be effective. Oral antivirals (acyclovir, famciclovir, or valacyclovir) may be recommended for severe or frequent attacks (six or more attacks per year) or for patients who are immunosuppressed. Various lotions, creams, and ointments may be prescribed to accelerate drying and healing of lesions (e.g., camphor, phenol, alcohol). Antibiotics may be indicated for secondary infections.

**Herpes Zoster (Shingles)**

**Pathophysiology and Etiology**
Herpes zoster, or shingles, is an acute inflammatory and infectious disorder that produces a painful vesicular eruption on bright red edematous plaques along the distribution of nerves from one or more posterior ganglia. This eruption follows the course of the cutaneous sensory nerve and is almost always unilateral (one-sided; Fig. 54.5).

Herpes zoster is caused by the varicella zoster virus—the same virus that causes chickenpox. After a case of chickenpox, the virus remains dormant in nerve tissue near the brain and spinal cord. Herpes zoster is a reactivation of this latent varicella virus. The incubation period of herpes zoster is 7 to 14 days. Vesicles appear in 3 to 4 days. Eruption usually occurs posteriorly and progresses anteriorly and peripherally along the dermatome. The total duration of the outbreak can vary from 10 days to 5 weeks.

This disease occurs most commonly in older adults or in those who have a diminished resistance, such as the patient with acquired immunodeficiency syndrome (AIDS), the patient on immunosuppressant agents, or the patient with a malignancy or injury to the spine or a cranial nerve.
Prevention

Avoidance of persons with herpes zoster during the contagious phase (a few days before eruption until vesicles dry or scab) is the best prevention. Varicella vaccine (Varivax) in children and adults who have not had chickenpox can reduce the risk of becoming infected with varicella. Another newer vaccine, Zostavax, is recommended for all patients over age 60 who have had chickenpox. It reduces the risk of shingles outbreak, and reduces the severity if it does occur.

Signs and Symptoms

In addition to the vesicles and plaques, there may be irritation, itching, fever, malaise, and, depending on the location of lesions, visceral involvement. Lesions may be very painful; the incidence of pain increases with age.

Complications

Postherpetic neuralgia, persistent dermalomal pain, and hyperesthesia are common in older adults and can last for weeks to months after the lesions have healed. The incidence and severity of these complications increase with age.

Ophthalmic herpes zoster affects the fifth cranial nerve and can be a serious complication. Consultation with an ophthalmologist is essential because this complication can affect eyesight. Other complications can occur with facial and acoustic nerve involvement, including hearing loss, tinnitus, facial paralysis, and vertigo. Full-thickness skin necrosis and scarring can occur if lesions do not heal properly; systemic infection can occur from scratching, causing the virus to enter the bloodstream.

Diagnostic Tests

Diagnosis is usually confirmed by history and physical examination of the patient and associated signs and symptoms. Cultures may be ordered if secondary bacterial infections are suspected.

Therapeutic Measures

Treatment is aimed at controlling the outbreak, reducing pain and discomfort, and preventing complications. Mild cases may heal without medication. Antiviral agents such as acyclovir are used for more severe cases and are most effective if started within 72 hours of the onset of the rash. Analgesics may be prescribed for pain and discomfort. Anticonvulsants (gabapentin/Neurontin) or antidepressants (amitriptyline/Elavil) may also be effective for neuropathic pain.

Use of corticosteroids is controversial, but they may help reduce discomfort and improve quality of life when used with antiviral agents. Topical steroids should not be applied if a secondary infection is present because they suppress the immune system. Antihistamines can be administered to control itching. Antibiotics are prescribed for secondary bacterial infections.

In addition to medications, cool compresses or baths may help with pain and itching. Topical agents containing calamine or lidocaine may also be helpful.

Fungal Infections

Pathophysiology and Etiology

Dermatomycosis, or a fungal infection of the skin, occurs when there is an impairment of the skin integrity in a warm, moist environment. This infection occurs through direct contact with infected humans, animals, or objects. Tinea is the term used to describe fungal skin infections; the name used after tinea indicates the body area affected. For example, tinea capitis is a fungal infection of the scalp, and tinea pedis is the term used for athlete’s foot. The term candidiasis is used when Candida is the infecting organism. Common fungal infections and treatments are described in Table 54.4.

Cellulitis

Pathophysiology and Etiology

Cellulitis is inflammation of the skin and subcutaneous tissue resulting from infection, usually with Staphylococcus or Streptococcus bacteria. Methicillin-resistant Staphylococcus aureus (MRSA) is becoming a common cause and is resistant to many antibiotics. Cellulitis can occur as a result of skin trauma; as a secondary bacterial infection of an open wound, such as a pressure ulcer; or it may be unrelated to skin trauma. It most often occurs in the extremities, especially the lower legs.

Prevention

Good hygiene and prevention of cross-contamination are important. If an open wound is present, preventing infection and promoting healing are critical.

Signs and Symptoms

The initial sign of cellulitis is a localized area of inflammation that may become more generalized if not treated promptly. Common clinical manifestations include warmth, redness, localized edema, pain, tenderness, fever, and lymphadenopathy. The infection can worsen rapidly and become systemic if not treated properly.

Diagnostic Tests

Culture and sensitivity testing of any pustules or drainage is necessary to identify the infecting organism. Blood cultures may also be indicated to rule out bacteremia.

Therapeutic Measures

Topical and systemic antibiotics are prescribed according to culture and sensitivity test results. Débridement of nonviable tissue is necessary if an open wound is present. Systemic antibiotics are indicated if fever and lymphadenopathy are present.

Elevation of the extremity can reduce pain and swelling. Monitor vital signs and report hypotension and tachycardia, because such changes can indicate systemic infection. Measure the extremity daily and document to monitor progress.

• WORD • BUILDING •

dermatomycosis: derma—skin + myco—fungus + osis—condition
### TABLE 54.4 Fungal Infections

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Treatment/Nursing Care</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Tinea Pedis (Athlete’s Foot)</strong></td>
<td>Common fungal infection, most frequently seen in those with warm, diaphoretic feet; occlusive shoes; or friction/trauma to the feet. Four types: interdigital (between the toes), chronic hyperkeratotic (chronic plantar erythema and scaling), inflammatory/vesicular (vesicles on plantar surface), and ulcerative (vesicular lesions and ulcers between toes and on plantar surface).</td>
<td>Administer topical antifungal agents as ordered; may be oral in more severe or unresponsive cases. Apply topical agents in a thin layer; treat for time specified, even after apparent clearing. Wet dressings or vinegar soaks may be ordered to dry blisters. Teach patient prevention measures: keep feet dry; dry carefully between toes; apply foot powder and wear cotton socks to absorb perspiration; if weather permits, use perforated shoes or sandals; avoid plastic or rubber-soled shoes; wear water shoes in public showers and near swimming pools.</td>
</tr>
<tr>
<td><strong>Tinea Capitis (Ringworm of Scalp)</strong></td>
<td>Contagious fungal infection of the scalp; commonly causes hair loss in children. Appears as scattered round, red, scaly patches; small papules or pustules may be evident at edges of patches; hair is brittle at site, breaks off, and temporary areas of baldness result; mild itching, tenderness, and pain may be present. Kerion is a severe inflammation of the scalp with resulting alopecia that sometimes occurs with tinea capitis.</td>
<td>Administer systemic antifungals as prescribed; relapse rate is high with topical agents. Oral corticosteroids are indicated for kerion inflammation to help prevent alopecia. Instruct family on contagious aspect of disease; assess other family members and pets for organism. Teach prevention measures: never share combs, brushes, pillowcases, or headgear.</td>
</tr>
<tr>
<td><strong>Tinea Corporis (Tinea Circinata, Ringworm of Body)</strong></td>
<td>Fungal infection of the body that appears as an erythematous macule; progresses to rings of vesicles or scale with a clear center that appears alone or in clusters; usually occurs on exposed areas of body; can be moderately to intensely itchy.</td>
<td>Administer topical or systemic antifungal agents as prescribed. Infected pet is common source of infection. Teach patient prevention measures: avoid heat, moisture, and friction; keep skin areas, especially folds, dry; use clean towel and washcloth daily; wear cotton clothing, especially on hot, humid days.</td>
</tr>
</tbody>
</table>
### TABLE 54.4 FUNGAL INFECTIONS—cont’d

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Treatment/Nursing Care</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Tinea Cruris (Ringworm of Groin, Jock Itch)</strong></td>
<td>Infection of groin, inner thighs, and buttocks area; may occur with tinea pedis; often in obese people who are participate in athletics. Lesion first appears as a small red scaly patch and then progresses to a sharply demarcated plaque with elevated scaly or vesicular borders; itching can range from minimal to severe.</td>
<td>Topical antifungals are prescribed; apply in a thin layer to rash and a few centimeters beyond border. Unresponsive cases may require oral antifungal agent. Teach patient prevention measures: bathe daily and change to clean underwear. Avoid tight clothing. Do not share personal items. Treat tinea pedis to prevent spread.</td>
</tr>
<tr>
<td><strong>Tinea Unguium (Ringworm of Nails, Onychomycosis)</strong></td>
<td>Chronic fungal infection of nails, usually the toenails; a lifelong disease. There is yellow thickening of nail plate; it is friable and lusterless. Eventually crumbly debris accumulates under free edge of the nail and causes nail plate to become separated; over time, the nail may become thinned, painful, and destroyed.</td>
<td>Systemic antifungals are rarely given for toenail involvement but may be prescribed for fingernail involvement. Topical antifungals are usually ineffective because they do not penetrate nails. Nail may have to be surgically removed (nail avulsion). Keep nails neatly trimmed and buffed flat; gently scrape out any nail debris.</td>
</tr>
<tr>
<td><strong>Candidiasis/Thrush</strong></td>
<td>Oral candidiasis is called thrush. Infection of skin or mucous membranes with <em>Candida</em>. Grows in warm moist areas such as under breasts, in groin, vagina, or oral mucous membranes. Appears as white patches in mouth, white vaginal discharge, or red irritated areas in skinfolds. May occur as a result of antibiotic therapy because normal flora that usually keep <em>Candida</em> in check are destroyed, or with corticosteroid therapy.</td>
<td>Administer oral or topical antifungal agents as ordered. Examples include nystatin “swish and swallow” or lozenges for oral thrush, nystatin powder or ointment for skin infection, or vaginal suppositories or creams. Teach patient to keep skin clean and dry, especially in skinfold areas. Treatment is important to prevent systemic infection.</td>

---

**Onychomycosis:** Onycho—fingernail or toenail + Myco—fungus + Osis—condition
Outlining the affected area with a marker can also help monitor progress but may be difficult if the borders are not clear.

**Acne Vulgaris**

*Pathophysiology and Etiology*

Acne vulgaris is a common skin disorder of the sebaceous glands and their hair follicles that usually occurs on the face, chest, upper back, and shoulders. The etiology is multifocal. The most common cause is hormonal changes during puberty. The sebaceous glands are under endocrine control, especially the androgens. Stimulation of androgens (e.g., during adolescence or the menstrual cycle) in turn stimulates the sebaceous glands to increase sebum production. This, along with gradual obstruction of the pilosebaceous ducts with accumulated debris, ruptures the sebaceous glands, which causes an inflammatory reaction that may lead to papules, pustules, nodules, and cysts. Acne occurs when the ducts through which this sebum flows become plugged.

Other factors that influence the occurrence and severity of acne include a hereditary tendency, stress, and external irritants such as strong soaps or cosmetics. Acne is not related to diet, chocolate, sexual activity, or uncleanliness.

**Prevention**

Acne vulgaris occurs regardless of interventions; however, certain interventions can lessen the severity or prevent complications. Avoidance of “picking” pimples prevents further inflammation and scarring. The patient should avoid excessive washing, irritants, and abrasives.

**Signs and Symptoms**

The initial lesions are called comedones (singular: *comedo*). Closed comedones, or whiteheads, are small white papules with tiny follicular openings. These may eventually become open comedones, or blackheads. The color is not caused by dirt but by lipids and melanin pigment. Scarring occurs as a result of significant skin inflammation; picking can worsen inflammation and lead to further scarring. The resulting inflammation can lead to papules, pustules, nodules (Fig. 54.6), cysts, or abscesses.

**Therapeutic Measures**

Medical treatment helps prevent new lesions and helps control current lesions. Effective topical agents include benzoyl peroxide (Desquam-X, Benzagel), which is an antibacterial agent that may help prevent pore plugging; antibiotics (erythromycin, tetracycline) to kill bacteria in follicles; and vitamin A acid (Retin-A, tretinoin) to loosen pore plugs and prevent occurrence of new comedones. Topical agents may be used alone or in combination. It may take 3 to 6 weeks before improvement is seen.

All topical agents should be applied with clean hands to acne-prone areas, not just where the acne occurs. They must be applied to dry skin. Medications should not be applied near eyes, nasolabial folds, or the corners of the mouth because of the potential for irritation. If the patient is ordered a combination of topical agents, unless contraindicated, the tretinoin is used at night and the others in the morning or afternoon. Tretinoin can be neutralized if mixed directly with other agents. The patient must be careful with sun or sunlamp exposure while using tretinoin. Also, remind the patient that it may be necessary to continue treatment even after the skin clears.

Systemic antibiotics (long term, low dose) and isotretinoin (Accutane) are usually reserved for severe cases of acne; the patient must be closely monitored for side effects. Estrogen therapy (oral contraceptives) may also be prescribed for young women; however, the risks often outweigh the benefits. Women should be aware that some antibiotics reduce the effectiveness of oral contraceptives.

Other medical treatments include comedone extraction, cryosurgery (freezing with liquid nitrogen), mild peeling (UV light, carbon dioxide, liquid nitrogen, mild acid), dermabrasion (deep chemical peel), excision of scars, and injection of fibrin or collagen below the scars. These treatments depend on the severity, age, condition, and physician and patient preference.

---

**NURSING CARE TIP**

Topical benzoyl peroxide may bleach colored fabrics. Have the patient wear a white cotton T-shirt under clothing if benzoyl peroxide is used on the back, and use an old or white pillowcase at night.

**Nursing Process for the Patient With a Skin Infection**

**Data Collection**

Subjective data collection regarding a skin infection can begin with the *WHAT’S UP?* acronym.

- Where is the skin infection located?
- How does it feel? Does it itch, burn, or hurt?
- What aggravates or alleviates the symptoms?
- Timing: How long has it been present?
- How severe is it?
- Useful other data: Is there swelling, drainage, or fever?
- Patient’s Perception: What does the patient think caused the infection?
Chapter 54  

Nursing Care of Patients With Skin Disorders  

Collection of objective data includes observing the affected area and describing the infection in terms of type and configuration of lesions, color, size, and presence of drainage. Also observe for swelling, and check for elevated temperature. If the patient has cellulitis of an extremity, measure and document the circumference of the extremity daily and as needed (prn).

Determine the patient’s understanding of the cause of the infection, and of infection control measures.

**Nursing Diagnoses, Planning, and Implementation**

**Risk for Infection (spread to surrounding or other areas)**

**EXPECTED OUTCOME:** The infected area will not spread to other areas on patient or to other individuals.

- Monitor and document size and location of infected area daily and prn. Careful monitoring can identify improvement or new spread of infection.
- Monitor temperature every 8 hours and prn. An increasing temperature can indicate worsening or systemic infection.
- Monitor for signs and symptoms of systemic spread of infection, such as hypotension, tachycardia, and increasing temperature. Systemic infection must be reported and treated promptly to prevent complications, including sepsis.
- Use standard precautions, including careful hand hygiene, when providing patient care to prevent transmission to yourself or to others.
- Implement appropriate isolation precautions for the patient with a contagious infection. Contact precautions are usually sufficient, although airborne precautions may be necessary if immunocompromised individuals are present. Isolation reduces spread of infection.
- Instruct the patient on wound care, appropriate hand hygiene, and disposal of soiled dressings. The patient must follow precautions to protect self and others.
- Instruct patient on use of prescribed anti-infective agents, including the importance of taking it exactly as directed to prevent development of a resistant infection.
- For the patient with acne, advise keeping hands away from the face and avoiding touching or squeezing pimples. Keep hair clean and off the face. These measures help prevent spread, secondary infection, and scarring.

**Acute Pain related to inflammation as evidenced by patient rating on appropriate pain scale**

**EXPECTED OUTCOME:** The patient will state that pain is controlled at an acceptable level.

- Monitor pain (if present) using a pain scale. Pain assessment provides a basis for nursing intervention.
- Administer analgesics as ordered, especially before dressing changes or treatments. Analgesics relieve pain and help prevent pain during dressing changes.
- For the patient with shingles:
  - Apply cool, moist compresses to painful or itching lesions to help cleanse and dry lesions and reduce itching.
  - Apply firm dressings such as wraps, stockings, or a snug T-shirt to reduce pain from post-herpetic neuralgia.

**Parasitic Skin Disorders**

**Pediculosis**

**Pathophysiology and Etiology**

Pediculosis is an infestation by lice. There are three basic types: pediculosis capitis (head lice), pediculosis corporis (body lice), and pediculosis pubis (pubic, or crab, lice). Generally, the lice bite the skin and feed on human blood, leaving their eggs and excrement, which can cause intense itching. The lice are oval and are approximately 2 mm in length.

In pediculosis capitis, the female louse lays e ggs (nits) close to the scalp, where the nits become firmly attached to hair shafts. The most common areas of infestation are the back of the scalp and behind the ears. The nits are about 1 to 3 mm in length and appear silvery white and glistening. Transmission is by direct contact or contact with infested objects, such as combs, brushes, wigs, hats, and bedding. It is most common in children and people with long hair.

Pediculosis corporis is caused by body lice that lay e ggs in the seams of clothing and then pierce the skin. Areas of the skin usually involved are the neck, trunk, and thighs.

Pediculosis pubis is caused by crab lice. It is generally localized in the genital region, but it can also be seen on hairs of the chest, axillae, eyelashes, and beard. The lice are about 2 mm in length and have a crablike appearance. It is chiefly transmitted through sexual contact or, to a lesser degree, by infested bed linens.

**Prevention**

Prevention involves avoidance of contact with an infected person or object. Brushes, combs, hats, and other personal items should not be shared. Good personal hygiene and routine clothes washing are other preventive measures; however, even someone with meticulous hygiene can develop an infestation if there is contact with the organism.

**Signs and Symptoms**

Pediculosis capitis can result in no itching or intense itching and scratching, especially at the back of the head. Nits may be noticeably attached to hair. A papular rash may be seen.

Pediculosis corporis may appear as tiny hemorrhagic points. Excoriation may be noted on the back, shoulders, abdomen, and extremities. It may also cause intense itching.

Pediculosis pubis results in mild to severe itching, especially at night. Black or reddish brown dots (lice excreta) may be noted at the base of hairs or in underclothing. Gray-blue macules may also be noted on the trunk, thighs, and axillae; this is the result of the insects’ saliva mixing with bilirubin.
Complications
Secondary bacterial infections can occur with pediculosis capitis, resulting in impetigo, furuncles, pustules, crusts, and matted hair. Complications of pediculosis corporis include secondary infection and hyperpigmentation. Most important, body lice may be vectors for rickettsial or other systemic disease. Complications with pediculosis pubis include dermatitis and the coexistence of other sexually transmitted infections.

Diagnostic Tests
Diagnosis is made through history and physical examination. The patient may also be tested for other sexually transmitted infections if pediculosis pubis is present.

Therapeutic Measures
Medical treatment is aimed at killing the parasites and mechanically removing nits. Over-the-counter (OTC) pediculicides containing pyrethrins or permethrin are the most commonly recommended compounds. These agents should kill the lice and nits, although some lice develop pesticide resistance, making mechanical removal necessary. Permethrin (Nix) remains active for about a week, killing the adult lice immediately and the nits when they hatch days later. Pyrethrins (RID, A-200 Pyrinate) must be reapplied in 1 week to kill newly hatched lice. Prescription treatments include benzyl alcohol lotion (Ulesfia), ivermectin lotion (Sklice), malathion lotion (Ovide), and spinosad (Natroba).

If initial treatment is not effective, lindane may be prescribed. Lindane is a controversial, highly toxic topical medication that is only used as a second-line agent.

Complications are treated, as appropriate, with antipruritics, topical corticosteroids, and systemic antibiotics. Physostigmine ophthalmic ointment is applied to affected eyebrows and eyelashes. Other medications should not be applied to eyebrows or eyelashes.

Patient Education
Reassure the patient and family that head lice can happen to anyone and that it is not a sign of uncleanliness. Lice infestations are treated on an outpatient basis, so patient education is important. Package instructions should be followed for correct usage of all medications.

Instruct the patient to bathe with soap and water and to disinfect combs and brushes in hot, medicated soap water. A fine-toothed comb dipped in vinegar can be used to remove nits from hairy areas. Nits can be removed from eyebrows and eyelashes with a cotton-tipped applicator after treatment. Clothing, linens, and towels should be laundered in hot water and detergent; unwashable clothing should be dry cleaned or sealed in a plastic bag for 10 days. Treatment should be started immediately to prevent rapid spread. Family members and close contacts (sexual contacts with pediculosis pubis) should be examined for infestation and should put on clean clothing.

Shampoos and lotions kill nits, but they do not remove them. To loosen nits from the scalp, the hair may be soaked in a solution of equal parts vinegar and water and a shower cap worn for 15 minutes. Then comb the hair with a fine-toothed comb and thoroughly rinse or shampoo to mechanically remove the nits. Children may return to school after adequate medical treatment, even if dead nits are still present.

Scabies
Pathophysiology and Etiology
Scabies is a contagious skin disease caused by the mite Sarcoptes scabiei. It results from intimate or prolonged skin contact or prolonged contact with infected clothing, bedding, or animals (e.g., dogs, cats, other small animals). The parasite burrows into the superficial layer of the skin (Fig. 54.7). These burrows appear as short, wavy, brownish black lines. The patient is asymptomatic while the organism multiplies, but it is most contagious at this time. Symptoms do not occur until almost 4 weeks after the time of contact.

Prevention
All persons (and animals) in intimate contact with an infected patient should be treated at the same time to eliminate the mites. The mites survive less than 24 hours without human contact. Therefore, bed linens, clothes, and to wels should be washed in hot water and dried at high heat, but furnishings need not be cleaned. Clean clothing and linens should be applied.

Signs and Symptoms
The major complaints are itching and rash. Itching can be intense, especially at night. Itching begins about 1 month after infestation and may persist for days to weeks after treatment. The rash appears as small, scattered erythematous papules, concentrated in finger webs, axillae, wrist folds, umbilicus, groin, and genitals. Crusts and scales may be present. Male patients may have excoriated papules on the penis and groin area.
Chapter 54  Nursing Care of Patients With Skin Disorders  1311

Complications

Hypersensitivity reactions to the mite can result in crusted lesions, vesicles, pustules, excoriations, and bacterial superinfections.

Diagnostic Tests

Diagnosis is confirmed by a superficial shaving of a lesion and microscopic evaluation for adult mites, eggs, or feces.

Therapeutic Measures

Topical scabicides (permethrin/Elimeite, crotamiton/Crotan) are used for chemical disinfection. Usually, the cream or lotion is applied in a thin layer to the entire body from neck to feet (including genitals, umbilicus, and skinfold areas), is left on overnight (8–12 hours), and is washed off in the morning; however, package instructions should be referred to for each medication. One or two applications are usually curative, depending on the agent prescribed. Antipruritics may be prescribed for itching.

Patient Education

A warm soapy bath or shower removes scales and skin debris. Advise the patient to apply the topical medication as ordered, not to use scabicides repeatedly because they can increase itching and cause further skin irritation, to follow medication directions, to treat family members and close contacts simultaneously to eliminate mites, to wear clean clothing, and to use clean linens. Remind the patient that itching may continue for up to 2 weeks after treatment until the allergic reaction subsides. (Dead mites remain in the epidermis until exfoliated.)

NURSING CARE TIP

Animals infested with scabies should be treated by a veterinarian, so they won’t infect humans.

PEMPHIGUS

Pathophysiology and Etiology

Pemphigus is an acute or chronic, serious skin disease characterized by the appearance of bullae (large fluid-filled blisters) of various sizes on otherwise normal skin and mucous membranes. The etiology is unclear, but it is known to be an autoimmune disorder. Sun exposure, genetic predisposition, and certain foods and drugs (e.g., penicillamine, captopril, and enalapril) may trigger the disorder. It usually occurs in patients from middle to older age. One type of pemphigus is associated with malignancy.

The autoimmune response that occurs in pemphigus causes a patient’s own antibodies to attack the skin and mucous membranes and destroy the protein “glue” that holds the cells together. The result is skin that separates from itself, causing the characteristic blisters.

Signs and Symptoms

Successive crops of bullae suddenly appear on skin or mucous membranes. The bullae are fragile and flaccid. They enlarge, rupture, and form painful, raw, eroded, partial-thickness wounds that bleed, ooze, and form crusts. Pemphigus usually originates in the oral mucosa and then spreads to the trunk. Large areas of the body become involved.

Besides the appearance of the bullae, the patient experiences pain, burning, and itching. The lesions have a foul smell. Involvement of the oral mucosa can interfere with chewing, swallowing, and talking. The patient is in constant misery.

Complications

The major complication is a secondary bacterial infection. This disease has high associated morbidity and mortality rates.

Diagnostic Tests

A positive Nikolsky’s sign is a characteristic finding. This occurs when there is sloughing or blistering of normal skin when minimal pressure is applied. A biopsy of a blister reveals acantholysis, or separation of epidermal cells from one another.

Therapeutic Measures

Treatment is aimed at controlling the disease, healing the skin, and preventing complications. Corticosteroids in large doses and immunosuppressants are prescribed to control the disease and bring about remission. Biological therapy (rituximab/Rituxan) targets the offending white blood cells. Medicated mouthwashes may be prescribed for mouth lesions. Antibiotic and antifungal agents are prescribed as needed for secondary infections. Analgesics and antipruritics are prescribed according to the patient’s specific signs and symptoms. Because of fluid, blood, and protein losses through the partial-thickness skin injuries, a high-protein, high-calorie diet is recommended, along with appropriate fluid replacement therapy. Generalized pemphigus lesions may be treated in the hospital with a therapeutic plasmapheresis to remove antibodies. Some cases clear up completely. Others require ongoing treatment.

Nursing Care

Monitor fluid balance with regular intake and output, body weight, and blood pressure measurement. Encourage the patient to maintain adequate fluid intake. Offer cool drinks often to lessen discomfort.

Tepid wet dressings or baths help lessen secondary infection, cleanse the area, decrease odor, and increase comfort. Potassium permanganate baths may decrease infection and clean and deodorize the area. Always thoroughly dissolve potassium permanganate crystals in a small container before adding to tub water. Undissolved crystals may further damage and burn the skin. Dry the patient thoroughly after the bath. Do not use tape on the patient because this may cause further blistering. Talcum powder may be used to keep the skin from sticking to clothing and bed linens.

• WORD • BUILDING • pemphigus: pemphix—blister
Skin lesions can be either benign (noncancerous) or malignant. Benign lesions are described in Table 54.5. Malignant lesions are discussed next. Also see “Cultural Considerations.”

Malignant Skin Lesions
Pathophysiology and Etiology

The most common skin malignancies include basal cell carcinoma, squamous cell carcinoma, and malignant melanoma. The major cause of skin malignancies is overexposure to ultraviolet rays, most commonly sunlight. Other factors include being fair skinned and blue eyed, genetic tendencies, history of x-ray therapy, exposure to certain chemical agents (e.g., arsenic, paraffin, coal tar), burn scars, chronic osteomyelitis, and immunosuppressive therapy.

Basal cell carcinoma arises from the basal cell layer of the epidermis. It is the most common type of skin cancer. This tumor is mainly seen on sun-exposed areas of the body. The lesion appears as a small pearly or translucent papule with a rolled, waxy edge, depressed center, telangiectasia (lesion formed by dilation of vessels), crusting, and ulceration (Fig. 54.8). Metastasis is rare, although it may be locally invasive.

Squamous cell carcinoma arises from the epidermis. It can occur on sun-exposed areas of the skin and mucous membranes and is mainly seen on the lower lip, neck, tongue, head, and dorsal surfaces of the hands. It can occur on normal skin or on a preexisting lesion (actinic keratosis). The lesion appears as a single, crusted, scaled, eroded papule, nodule, or plaque (Fig. 54.9). A neglected lesion appears more rough, scaly, and darker colored. The lesion is fragile and prone to oozing and bleeding. Untreated squamous cell carcinoma can metastasize to distant areas of the body.

Malignant melanoma, as the name implies, is a malignant growth of pigment cells (melanocytes, Fig. 54.10). It is highly metastatic, with a higher mortality rate than basal or squamous cell carcinomas. This tumor can occur anywhere on the body; about half arise from preexisting nevi or moles. There are three general types: lentigo maligna, superficial spreading, and nodular.

Lentigo maligna melanoma appears as a slowly growing dark macule on exposed skin surfaces (especially the face) of older adults (Fig. 54.11). The lesion has irregular borders and brown, tan, and black coloring. Prognosis is good if treated in the early stage.

Superficial spreading melanoma is the most common melanoma. It can occur anywhere on the body and is usually seen in middle-aged persons. The lesion appears as a slightly elevated plaque with an irregular border. The coloring of the lesion varies in combinations of black, brown, and pink. The fragile surface may bleed or ooze. Eventually the plaque develops into a nodule. The cure rate is excellent when it is in the plaque phase; prognosis is poor in the nodular phase.

Nodular melanoma occurs suddenly as a spherical papule or nodule on the skin or in a mole. Coloration is blue-black, blue-gray, or reddish blue color that may have a rim of inflammation. The lesion is fragile and bleeds easily. Metastasis occurs rapidly. This type of melanoma has the least favorable prognosis. Early diagnosis and treatment is imperative.

Prevention
Risk of most types of skin cancer can be reduced by limiting or avoiding direct exposure to UV rays (sun, tanning booths). If exposure to the sun is necessary, exposure should be avoided during its highest intensity (between 1000 and 1600).

Cultural Considerations

• Darker skinned people have a tendency toward an overgrowth of connective tissue components concerned with the protection against infection and repair after injury. Keloid formation is one example of this tendency toward overgrowth of connective tissue. Lymphoma and systemic lupus erythematosus may occur due to this overgrowth of connective tissue.
• Some African American men have facial hair that is kinky, curls back on itself, and penetrates the skin, which can result in pustules and small keloids. Many use depilatories or electric razors to prevent nicking the skin, which can also cause keloids.
• Darker skinned people have an increased incidence of birthmarks and Mongolian spots compared with lighter skinned people. Mongolian spots disappear over time. The nurse must be cautious not to mistake these spots for bruising, which can indicate injury or abuse.
• For people with light skin, such as those of German, Polish, and Irish descent, prolonged exposure to the sun may increase the incidence of skin cancer. Teach patients to protect themselves from sun exposure to reduce their risk of skin cancer. Nevi (freckles and skin discolorations) occur more often in lighter skinned individuals. They are most common in European Americans, followed by Asians, and then darker skinned African Americans.
### TABLE 54.5 BENIGN SKIN LESIONS

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cyst</td>
<td>A saclike growth with a defined wall that may contain liquid, semifluid, or solid material. An epidermoid cyst is the most common type of cyst. It results from proliferation of epidermal cells in the dermis. Rarely, it is associated with carcinoma development.</td>
<td>Not all cysts need to be treated. Treatments include intralesional steroid therapy and antibiotics, if indicated. If excision is done, the entire cyst wall is removed to prevent recurrence.</td>
</tr>
<tr>
<td>Seborrheic Keratosis</td>
<td>A benign skin lesion with pigmented light tan to dark brown patches. The plaques or papules have a “stuck-on” appearance caused by the proliferation of epidermal cells and keratin piled on the skin surface. Cause is unknown, but it tends to occur in middle-aged to older patients, most commonly on the trunk, scalp, face, and extremities.</td>
<td>Treatment is cosmetic only, or if lesion becomes irritated from friction. Topical agents may be used to reduce lesion size or height. Liquid nitrogen cryotherapy or light curettage may be performed if necessary for removal.</td>
</tr>
</tbody>
</table>

</tr>
</thead>
<tbody>
<tr>
<td><strong>Keloid</strong></td>
<td>A benign growth of fibrous tissue (scar formation) at the site of trauma or surgical incision; occurs in various sizes. Growth of tissue is out of proportion to what is needed for normal healing. The lesion extends beyond the original injury and occurs mainly in middle-aged and older adult clients and darker skinned patients.</td>
<td>Treatment varies and is not always successful; a larger scar may ensue. Some treatment options include compression therapy, corticosteroid injections into lesions, excision, and laser therapy.</td>
</tr>
<tr>
<td><strong>Pigmented Nevus (mole)</strong></td>
<td>A benign, flesh-colored to dark brown macule or papule located randomly over the entire skin surface of the body. Can be inherited or acquired and occurs mostly in light-skinned patients. Usually begin to appear between 1 and 4 years of age, increasing in number into adulthood. Some contain a few hairs. There are many variations. Rate of transformation to a malignant melanoma is higher in congenital moles and larger lesions. Clinical signs of melanoma include change in color or size; inflammation of surrounding skin; irregular or spreading borders; variegated colors, especially a bluish pigmentation; bleeding; and oozing, crusting, and itching. Usually nevi larger than 1 cm should be carefully examined.</td>
<td>Treatment is indicated for risk of melanoma, unsightly nevi (cosmetic), repeated irritation (rubbing from belt, bra), trauma, large moles, and client report of a change in the mole. Surgical removal can include excision (preferred) or surgical shave. All excised moles should be sent for histological examination.</td>
</tr>
</tbody>
</table>

<tr>
<th>Type</th>
<th>Description</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wart</td>
<td>Small, common, benign growth of the skin resulting from the hypertrophy of the papillae and epidermis; caused by a virus. Common warts, often seen on hands and fingers, appear as raised, flesh-colored papules that have a rough surface. May crack, fissure, bleed, and be painful to lateral pinching and direct, firm pressure. Plantar warts occur on the sole of the foot. They may appear granular, pitted, or protuberant, with a callus of surrounding normal skin. Incubation period can be several weeks to months. Virus is spread by direct contact.</td>
<td>Patient should be cautioned not to spread lesions by picking or biting them. Treatment is indicated for symptomatic warts and for cosmetic purposes. General treatments include keratolytic agents (e.g., salicylic acid plasters) to soften and reduce keratin; cryotherapy (liquid nitrogen); and light electrodessication and curettage (requires local anesthesia).</td>
</tr>
<tr>
<td>Nevus flammeus</td>
<td>Benign vascular tumor of dilated blood vessels that can have varied clinical manifestations. Nevus flammeus involves mature capillaries on the face and neck. It is a congenital neoplasm that appears as a pink-red to bluish purple macular patch. Port-wine stains or port-wine angiommas appear as violet-red macular patches, usually singular lesions, growing proportionately as the child grows. These lesions can persist indefinitely. Cherry hemangiomas are commonly seen in older adults. They appear as small round papules that can vary in color from red to purple. Nevus flammeus is usually treated for cosmetic reasons. Port-wine stains, if large enough, may be treated surgically or with pulse-dye laser therapy. Cosmetics to camouflage the affected area are also available. Treatment for cherry hemangiomas is usually not prescribed, except for cosmetic purposes.</td>
<td></td>
</tr>
<tr>
<td>Hemangioma (Angioma)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The patient should use a protective sunscreen with sun protection factor (SPF) of 15 or more, and wear sun-protective clothing such as hats and long sleeves. The patient should seek medical advice if there is a change in color, size, shape, sensation, or character of a lesion or mole.

**Diagnostic Tests**

A preliminary diagnosis can be based on the appearance of the lesion. A definitive diagnosis is made by biopsy. Other tests are performed based on the results of the pathological examination.

**Therapeutic Measures**

Medical treatment depends on the type, thickness, and location of the lesion; the stage of the disease; and the age and general health of the patient. Generally, lesions are surgically excised with a 1- to 2-cm margin to make sure no cancer cells remain. Regional node dissection varies; it may be advised if the nodes in the area drain to one group. Grafting may be necessary for closure or repair. Chemotherapy may be used for metastasis. Radiation therapy may be used as adjunct treatment or may be
recommended for patients with a deeply invasive tumor or those who are poor surgical risks. Other therapies include cryosurgery or curettage and electrodesiccation.

**Nursing Care**

Perform a complete skin examination. Palpate lesions to determine texture, size, and firmness. Document size, location, color, surface characteristics, pain, discomfort, itching, and bleeding. Note when the patient first discovered the lesion.

Nursing care of the patient with cancer is documented in Chapter 11. Specific nursing care related to cryosurgery includes preparing the patient for the procedure. Explain that minor discomfort can be expected with little or no local anesthesia. Expect swelling, local tenderness, and hemorrhagic blister formation 1 to 2 days after the procedure. After the procedure, the area is cleansed as ordered and prescribed ointments are applied.

Specific nursing care for curettage and electrodesiccation includes preparing the patient for the procedure. After local anesthesia, a dermal curette is used to scrape away the lesion, followed by electrodesiccation of the remaining wound; the wound heals by secondary intention, usually with minimal scarring. After the procedure, the wound is cleansed and dressed as prescribed.
Plastic or reconstructive surgery is performed to correct certain defects, scars, and malformations and to restore function or prevent further loss of function. This type of surgery is usually an elective procedure; it may be prescribed by the HCP, or it may be the wish of the patient hoping to improve body image. Common types of plastic surgical procedures are listed in Table 54.6. Care of the surgical patient is covered in Chapter 12.

### NURSING CARE TIP

To help patients find melanomas as early as possible, encourage them to examine their skin regularly and report any lesions that fit this profile:

- Asymmetrical shape
- Irregular or poorly defined border
- Variable color
- Diameter larger than that of a pencil eraser
- Changing appearance

Home Health Hints

- A wound-measuring device that will not be misplaced is your hand. Measure your hand, such as the nailbed of a particular finger or the space between joints. Use these as a guide to determine wound measurements.
- Sanitary pads make great cushions for bony prominences. You can also place them in a cotton sock for better molding.
- A handheld shower head is useful for debriding some leg ulcers. Do not use it if it is too painful.
- To relieve pruritus (itchy skin), oatmeal baths are sometimes prescribed. An inexpensive way to do this is to place a half cup of quick-cooking oatmeal in a cotton sock. Put it under the faucet as you fill the tub and ring out the sock.
- Instruct patients to prevent red, dried, cracked skin on hands by wearing gloves outside in the cold or windy weather to prevent chapping, avoiding overheating the house, using a humidifier to keep the air moist, applying hand lotion two or three times a day and after each hand washing, using soaps with added oil and avoiding those with deodorants, using sunscreen with an SPF factor of at least 15, and stopping smoking (smoking reduces blood flow to the skin).
- If necessary, a specialty bed or mattress can be obtained to use in a patient’s home.
- Instruct patients who are confined to a wheelchair to rise up briefly, using their armrests, and shift weight every 15 minutes to prevent pressure ulcers.
- Instruct patients with dressings to keep them clean and dry. Unless the patient or caregiver has been instructed on how to perform the dressing change, inform him or her to contact the home care agency if the dressing falls off.
- A patient can wear a cast shoe over a dressing on the foot. This will help protect the dressing and provide additional support for the patient while ambulating.
- Surgi-net, or a similar stretchy cover, can be used to cover dressings for patients with tape sensitivities. They are also good for additional support to prevent a dressing from falling off.

CRITICAL THINKING

- **Mr. Russ**
  1. Perform a Braden Scale assessment. A specialty pressure-relieving bed may be appropriate for Mr. Russ.
     - Change Mr. Russ’s position at least every 2 hours if not more frequently. Keep his heels off of the bed at all times by propping them on pillows.
     - Request a dietary consult because the body cannot meet the increased healing demands if there is an albumin deficiency. Mr. Russ may need increased protein (contraindicated in renal failure). He may also need fats, carbohydrates, vitamins, and minerals for wound healing. A dietitian can help determine the amounts of calories and types of foods for the best prevention and/or healing.
     - If Mr. Russ is able to sit up in a chair, provide a chair cushion to prevent skin breakdown and have him shift his weight every 15 minutes.
     - Mr. Russ is wearing a brace, so examine the underlying tissue for pressure areas. Braces and splints must be padded to avoid skin breakdown.

- **Mrs. Long**
  Ask how long she is leaving the shampoo in her hair. For medicated scalp shampoos to work properly, they must remain on the scalp for several minutes. Package instructions should be carefully checked for each product because they vary from product to product.
Chapter 54  Nursing Care of Patients With Skin Disorders

REVIEW QUESTIONS

1. The nurse notes scratch marks on a patient with psoriasis. What are interventions that will decrease itching and protect the skin that the nurse can teach the patient?  
Select all that apply.  
1. Apply pressure to the itchy area with a clean cloth.  
2. Encourage use of gloves at night.  
4. Consider taking an antihistamine at bedtime.  
5. Use a room humidifier.  

2. What information is most important for the nurse to teach patients about avoiding malignant skin lesions?  
1. Shower or bathe daily.  
2. Avoid contact with allergens and irritants.  
3. Avoid overexposure to ultraviolet rays.  
4. Avoid others with malignant lesions.  

3. The nurse notes a pressure wound on a newly admitted patient’s ischial tuberosity, with a thick, tough black center. Which intervention is most appropriate first?  
1. Coat the ulcer with antibiotic ointment.  
2. Snip away the black tissue with sterile scissors.  
3. Flush the wound with sterile saline.  
4. Talk to the HCP about débridement.  

4. A patient develops wounds on the sacrum and buttocks despite being turned and repositioned regularly. Which factors may have contributed to the patient’s skin breakdown? Select all that apply.  
1. The patient is 20 pounds overweight.  
2. The patient commonly slides down in the chair.  
3. Staff use a lift sheet to move the patient in bed.  
4. The patient sits in a chair most of the day.  
5. The patient is often diaphoretic.  
6. The patient is incontinent of urine and stool.  

5. Which instruction should the nurse provide to the patient being treated for scabies?  
1. “Dry clean all linens, towels, and clothes.”  
2. “Wash linens, towels, and clothes.”  
3. “Discard infested mattresses.”  
4. “Remove infested pets from the home.”  

6. A patient diagnosed with impetigo contagiosa wants to know when the disease will no longer be contagious. Which response by the nurse is correct?  
1. One week after treatment is started  
2. After spread of lesions has stopped  
3. After all the lesions crust over  
4. When all lesions are healed

Answers can be found in Appendix C.

Nursing Care of Patients With Burns

RITA BOLEK TROFINO

LEARNING OUTCOMES

1. Explain the pathophysiology of burns.
2. Describe current therapeutic measures used for burns.
3. List data to collect when caring for patients with burns.
5. Explain how you will know if your nursing interventions have been effective.
Many people are hospitalized each year for burns. Burns affect not only the skin but also every major body system. Smoke inhalation and wound infections complicate care of the patient who has been burned.

**PATHOPHYSIOLOGY AND SIGNS AND SYMPTOMS**

Burns are wounds caused by an energy transfer from a heat source to the body, heating the tissue enough to cause damage. Locally, the heat denatures cellular protein and interrupts the blood supply. The three zones of tissue damage that occur with burns are described in Figure 55.1.

The amount of skin damage is related to (1) the temperature of the burning agent, (2) the burning agent itself, (3) the duration of exposure, (4) the conductivity of tissue, and (5) the thickness of the involved dermal structures.

Alterations in normal skin function resulting from a major burn injury include loss of protective functions, impaired ability to regulate temperature, increased risk of infection, changes in sensory function, loss of fluids, impaired skin regeneration, and impaired secretory and excretory functions.

**Systemic Responses**

Alterations in the functional capacity of the skin in response to a burn affect virtually all major body systems.

**Fluid Balance**

Following a major burn, increased capillary permeability leads to the leakage of plasma and proteins into the tissue, resulting in the formation of edema and loss of intravascular volume. There is also water loss by evaporation through the burned tissue that can be 4 to 15 times normal. Increased metabolism leads to further water loss through the respiratory system.

**Cardiac Function**

A burn is followed by an initial decrease in cardiac output, which is further compromised by the loss of circulating plasma volume. Severe hematologic changes resulting from tissue damage and vascular changes occur in patients with major burns. Plasma moves into the interstitial space because of increased capillary permeability. In the first 48 hours after a burn, fluid shifts lead to hypovolemia and, if untreated, hypovolemic shock. Loss of intravascular fluid causes a relative increase in hematocrit, and red blood cells are destroyed. The intense heat decreases platelet function and half-life. Leukocyte and platelet aggregation may progress to thrombosis.

**Metabolic Changes**

Metabolic demands are very high in patients with burns. A high metabolic rate proportional to the severity of the burn is usually maintained until wound closure. This hypermetabolism is further compromised by associated injuries, surgical interventions, and the stress response. Severe catabolism also begins early and is associated with a negative nitrogen balance, weight loss, and decreased wound healing. Elevated catecholamine (epinephrine, norepinephrine) levels are triggered by the stress response. This, along with elevated glucagon levels, can stimulate hyperglycemia.

**Gastrointestinal Problems**

A few of the gastrointestinal (GI) problems that can develop with a major burn include gastric dilation, peptic ulcers, and paralytic ileus. Most of these problems occur in response to fluid shifting, dehydration, opioid analgesics, immobility, depressed gastric motility, and the stress response.
Renal Function

Acute renal insufficiency can occur as a result of hypovolemia and decreased cardiac output. Fluid loss and inadequate fluid replacement can lead to decreased renal blood flow and glomerular filtration rate. Extensive burns can cause destruction of muscle, creating myoglobin casts that can block renal tubules and lead to renal failure.

Pulmonary Effects

Pulmonary effects are mostly related to smoke inhalation. However, hyperventilation may occur with any moderate to major burn injury, usually proportional to the severity of the burn. Oxygen consumption increases because of the hypermetabolic state, fear, anxiety, and pain.

Evaluation of Burn Injuries

The severity of a burn injury is determined by the depth of tissue destruction (Table 55.1 and Fig. 55.2), percentage of body surface area injured, cause of the burn, age of the patient, additional injuries, medical history (e.g., heart disease, diabetes), and location of the burn wound.

The size of a burn wound is estimated based on parts of the body affected. A quick and common method is the Rule of Nines. This method divides the body into segments whose areas are either 9% or multiples of 9% of the total body surface, with the perineum being counted as 1% (Fig. 55.3). This formula is easy, but it is not as accurate when assessing children. A more accurate method uses a table with a relative anatomical scale or diagram that estimates total burned area by ages and by smaller anatomical areas of the body.

Immune Function

With the skin destroyed, the body loses its first line of defense against infection. Major burns also depress immunoglobulins (Ig)A, IgG, and IgM.

BE SAFE!

BE VIGILANT! You must be vigilant in monitoring for infection, as infection is a real and life-threatening risk to severely burned patients.

Burn injuries have many causes. The most common causes include flames, contact burns, scalding, and chemical, electrical, and radiation burns. Table 55.2 summarizes common causes; see also “Gerontological Issues.”
COMPLICATIONS

A major complication that can occur with a flame burn in an enclosed space is inhalation injury. An inhalation injury is a major cause of morbidity and mortality associated with burn injuries. Treatment of an inhalation injury takes precedence over other injuries. (Remember your ABCs? Airway always comes first.) Infection is another common complication with a major burn. The incidence of infection increases with the size of the burn wound because the skin is the first line of defense against microorganisms.

Neurovascular compromise can also occur with a major burn. Eschar formation creates pressure and contrib utes to decreasing blood flow to areas distal to the burned area. Other systemic complications were reviewed in the “Systemic Responses” section earlier in this chapter.

DIAGNOSTIC TESTS

Burns are diagnosed by physical assessment. Various diagnostic tests are performed for systemic reactions, infection, and other complications. Common laboratory tests include
complete blood cell count (CBC) and differential, blood urea nitrogen (BUN), serum glucose and electrolytes, serum protein and albumin levels, urinalysis, urine cultures, and clotting studies. If an inhalation injury is suspected, arterial blood gases, bronchoscopy, and carboxyhemoglobin levels are done. X-rays, electrocardiogram, and wound cultures are completed if indicated.

**THERAPEUTIC MEASURES**

Therapeutic interventions vary according to the severity of the burn and the stage the patient is in. Treatment is managed over three overlapping stages (Table 55.3).

**Emergent Stage**

At the time of injury, the burning process must be stopped. The clothes are removed, and the wound is cooled with tepid water and covered with clean sheets to decrease shivering and contamination. The burn wound itself is a lower priority than the ABCs (airway, breathing, circulation) of trauma resuscitation. Emergency rescuers at the scene will stabilize the victim by establishing an airway, ensuring oxygenation, inserting an IV line, and stabilizing fractures, hemorrhage, and spinal and other injuries. Inhalation injury is suspected if the patient sustained a burn from a fire in an enclosed space or was exposed to smoldering materials, if the face and neck were burned, if there are vocal changes, or if the patient is coughing up carbon particles. IV fluids are given to prevent and treat hypovolemic shock. The patient is treated for pain with appropriate IV opioid analgesics.

An accurate history of the injury is obtained to determine severity, potential complications, and any associated trauma. The patient’s medical history is also obtained. Admission to the facility and burn care treatment are explained to the patient and family.

**Acute Stage**

If the patient is in a facility with a special burn unit, multidisciplinary care from a burn team is provided during the acute stage. Management goals include wound closure with no infection, minimum scarring, maximum function, maintenance of comfort as much as possible, adequate nutritional support, and maintenance of fluid, electrolyte, and acid–base balance. The patient continues to be medicated for pain as needed, especially before painful treatments. Patient-controlled analgesia (PCA) is very effective. Nutritional support may be maintained via nasogastric feeding tube (see “Nutrition Notes”).

**Nutrition Notes**

**Burns**

The goals of nutritional support in burned patients are to (1) meet metabolic needs, (2) promote wound healing, (3) promote resistance to infection, and (4) reduce protein loss (severely burned patients can lose nearly one-half pound of skeletal muscle per day).

Early (within 6–12 hours of injury) aggressive enteral feeding into the duodenum or jejunum improves outcomes. Because carbohydrates rather than fats are the best sources of energy after burn injury, formulas may contain 82% carbohydrate, 15% protein, and 3% fat. Protein needs are at least 1.5 to 2 grams/kilogram of body weight/day. Compared with omega-6 fatty acids, omega-3 fatty acids have been associated with an improved inflammatory response. Multivitamin/multimineral supplements are normally included.

Other nutrients and components that might be considered as supplements are the following:
- Vitamin C, up to 20 times the recommended dietary allowance, for collagen synthesis
- Vitamin A for wound healing and epithelial growth
- Zinc for wound healing and lymphocyte function
- The amino acid glutamine to improve visceral protein levels and decrease incidence of infections

The wound is cleansed and débrided daily to promote healing, prevent infection, and provide a clean bed for grafting. Wound cleansing is achieved by showering using a shower trolley or shower chair and bedside care. Débridement, or the removal of nonviable tissue (eschar), can be mechanical, chemical, surgical, or a combination of these methods. Mechanical débridement can involve the use of scissors and forceps to manually excise loose, nonviable tissue, or the use of wet-to-moist or wet-to-dry fine-mesh gauze dressings (see Chapter 54). Chemical débridement involves the use of a proteolytic enzymatic debriding agent that digests necrotic tissue. Surgical débridement is the excision of full-thickness and deep partial-thickness burns. This method is followed by application of a skin graft.

If the patient has a circumferential burn (one that surrounds an extremity or area), an increase in tissue pressure secondary to tissue edema occurs. The burn then acts like a tourniquet, impeding arterial and venous flow and impairing distal pulses. Common sites for these burns are the extremities, trunk, and chest. If this occurs on the chest and trunk, respiratory insufficiency can occur as a result of restricted chest expansion. An escharotomy may be immediately needed to relieve pressure. An escharotomy is a linear excision through the eschar to the superficial fat that allows for expansion of the skin and return of blood flow or chest expansion (Fig. 55.4).

After the area is cleaned, the burn dressing and topical treatment are prescribed. The type of dressing and topical agent chosen depend on the area inolved, the extent and depth of injury, and physician preference. Several common topical agents are listed in Table 55.4.

Dressings may be open, closed, biological, synthetic, or a combination. The open method is the use of a topical agent without any dressing. The closed method involves the use of an occlusive dressing over the wound. General principles for dressings include the following:

1. Limit the bulk of the dressing to facilitate range of motion.
2. Never wrap skin-to-skin surfaces (e.g., wrap fingers or toes separately; place a donut gauze dressing around the ear).
3. Base dressings on the size of wounds, absorption, protection, and type of débridement.
4. Wrap extremities from distal to proximal to promote venous return.
5. Do not wrap dressings too tightly. Check peripheral pulses often.

The term biological dressing refers to a dressing that uses tissue from living or deceased humans (cadaver skin) or deceased animals (e.g., pigskin) or to cellular dressings that may use animal tissue, human tissue, or synthetics. Biological dressings assist with wound healing and stimulate epithelialization. These dressings may be used as donor site dressings, to manage a partial-thickness burn and to cover the clean, excised wound before autografting. Some cellular wound dressings have varied layers that form a matrix onto which the patient's own cells migrate over a few weeks to form a new dermis. A very thin layer of the person's own skin is then grafted onto this new dermis.

Synthetic dressings are used in the management of partial-thickness burns and donor sites. Synthetic dressings are more readily available, less costly, and easier to store than biological dressings. They are made from a variety of materials and come in many sizes and shapes. Most of these dressings contain no antimicrobial agents.
Biological and synthetic dressings are used as temporary wound coverings over clean partial- and full-thickness injuries. They act as skin substitutes to help maintain the wound surface until healing occurs, a donor site becomes available, or the wound is ready for autografting.

**Skin Grafts**

**AUTOGRAFT.** An autograft is a skin graft from the patient’s unburned skin that is placed on the clean excised burn. The two common types of autografts are the split-thickness skin graft (STSG), which includes the epidermis and part of the dermis, and the full-thickness skin graft (FTSG), which includes the epidermis and entire dermal layer.

**SPLIT THICKNESS SKIN GRAFT.** An STSG (0.006–0.016 inch or 0.15–0.41 mm) may be applied as a sheet graft or a meshed graft. A sheet graft is used for cosmetic effect, such as for a face, neck, upper chest, breast, or hand burn. It is placed on the area as a full sheet. A meshed graft is passed through a mesher that produces tiny splits in the skin, similar to a fishnet, with openings in the shape of diamonds (Fig. 55.5), to permit the skin to expand one and a half to nine times its original size. The meshing allows for coverage of a large burn area with a small piece of skin by stretching it and securing it with sutures or staples. A mesh graft is especially useful when a patient’s burns are extensive, resulting in few available donor sites. Graft “take,” or vascularization, is complete in about 3 to 5 days.

**FULL THICKNESS SKIN GRAFT.** FTSGs (0.035–0.040 inch or 0.9–1.02 mm) can be sheet grafts or pedicle flaps. They are used over areas of muscle mass, soft tissue loss, hands, feet, and eyelids. They are not used for extensive wounds

**WORD BUILDING**

autograft: auto—self + graft—tissue transplant
because the donor sites usually require an STSG for closure, or closure from the wound edges. A pedicle graft or flap is a skin flap and subcutaneous tissue that is still attached at one corner by a “pedicle” to a blood supply (artery and vein); it is then attached to an adjacent area in need of grafting. Once the distal part of the graft takes, it remains in place and the flap is divided, with the remainder returning to the original site. Pedicle flaps are not as popular as free skin flaps because they require more than one surgery and take longer for the graft site and donor site to heal. Table 55.5 provides a comparison of split-thickness and full-thickness grafts.

Donor sites are considered partial-thickness wounds. Donor sites usually heal in 10 to 14 days, but this depends on the thickness and method of grafting and the general health of the patient. Treatment for the donor site varies with the individual patient, the area of the body, and physician preference. Considerations for care include promoting comfort and preventing trauma and infection. Use of semiocclusive, transparent dressings such as Op-Site, Biobrane, or Tegaderm, allows for a moist healing environment and is associated with reduced risk of infection. The donor site is very painful. Appropriate pain medications are provided, along with nonpharmacologic measures (e.g., back rubs or distraction).

With any type of graft, the patient must keep the graft site immobilized until the graft takes, to prevent movement or slippage of the grafted skin. Dressings may be bulky to assist in immobilization. These dressings must not be disturbed. The involved area requires frequent circulatory checks, including assessment of color, warmth, sensation, pulses, and capillary refill. Any involved extremities must be elevated to maintain circulation. Table 55.6 describes factors that affect graft viability. A graft has been successful if there is good adherence of the graft to the wound with no evidence of necrosis or infection.

### Rehabilitation Stage

The therapy started during the acute phase continues in the rehabilitation phase. There is wound closure, and the goal is to return the patient to an optimum level of physical and psychosocial function. This may take months to years to accomplish, depending on the extent of the injury. Reconstructive surgeries may be ongoing for many years.

Two things to keep in mind when caring for the patient with a major burn are that (1) the most comfortable position (flexion) is the position of contracture, and (2) the burn wound will shorten until it meets an opposing force. Have you ever seen a contracture? They are uncomfortable and debilitating. To avoid contractures (Fig. 55.6), a specific
exercise program is begun 24 to 48 hours after injury, along with the use of splinting devices to maintain proper positioning and stretching. Hypertrophic scarring, or a proliferation of scar tissue, can be minimized or prevented through the use of a pressure garment (Fig. 55.7).

As the burn heals, itching may occur and may be intense at times. It is important to control itching, because scratching can impair healing and increase risk of infection (see “Evidence-Based Practice”).

Psychosocial Effects of Burn Injury
A burn affects the patient’s psychosocial status in many ways. The magnitude of these effects are related to the age of the patient, location of the burn (e.g., face, hands), recovery from injury, cause of the injury (especially if related to negligence or a deliberate act), and ability to continue at the preburn level of normal daily activities. The patient may experience a disruption of role function and general health and coping ability. Treatment involves the patient and significant others. Referrals to support groups, counselors, and psychiatrists are important during this stage.

EVIDENCE-BASED PRACTICE
Clinical Question
What interventions are helpful for treating itching in a healing burn?

Evidence
Itching (pruritis) can interfere with activities of daily living. Treatment of itching can include pharmacologic and nonpharmacologic approaches. Some treatments shown to be helpful include cimetidine (an oral antihistamine), colloidal oatmeal baths, and pulsed dye laser therapy (Bell & Gabriel, 2009; UT Southwestern Medical Center, 2009). Nonpharmacologic techniques include massage and application of cold (Kagan et al, 2013).

Implications for Nursing Practice
Postburn itching affects about 87% of patients. Pruritus can increase pain and cause insomnia. It can range from mild to severe. Be sure to assess the presence and severity of itching on a 0-to-10 scale and advocate for appropriate orders.

REFERENCES

CRITICAL THINKING
Mrs. Potter
Mrs. Potter is recovering from partial-thickness burns and skin grafts. She mentions that she and her family will be going on a much-needed vacation to the shore. What concerns do you have?
Suggested answers are at end of the chapter.

NURSING CARE TIP
Use caution with heating pads, water temperature, and electrical equipment when working with your patients. Burns are considered serious.

NURSING PROCESS FOR A PATIENT WITH A BURN INJURY

Data Collection

A major burn is painful and frightening for the patient and frightening for the family. Obtain information from the patient, family, and rescuers. If the injury occurred in an enclosed space with flames or smoldering materials, suspect an inhalation injury. If an electrical injury has occurred, ask about voltage, duration of contact, host susceptibility (wet or dry skin), entry and exit sites, and associated falls. With chemical burns, determine type of agent and duration of exposure.

General information to collect for all burns (in addition to normally collected data, such as medical history, allergies, and current medications) includes extent, depth, type, and location of the burn; burn agent; duration of contact with the burning agent; severity and location of pain; and associated injuries. Determine the immediate first aid treatment provided at the scene. Obtain psychosocial information: other people injured, additional losses (home, pets), whether the patient was at fault, and how this injury affects the patient’s role function.

Nursing Diagnoses, Planning, Implementation, and Evaluation

See the “Nursing Care Plan for the Patient with a Burn Injury,” and Table 55.7, “Burn Summary.” For more information on burns, go to the American Burn Association Web site at www.ameriburn.org.

NURSING CARE PLAN for the Patient With a Burn Injury

Nursing Diagnosis: Impaired Gas Exchange related to upper airway edema, carbon monoxide poisoning, edema of alveolar capillary membranes, as evidenced by abnormal blood gases, elevated CO level

Expected Outcomes: The patient’s gas exchange will be improved as evidenced by patent airway, CO level less than 10%, clear lung sounds, PaO₂ 80–100 mm Hg, PaCO₂ 35–45 mm Hg, SpO₂ ≥95%, responsiveness, and awareness.

Evaluation of Outcomes: Are oxygenation levels improved? Do the lungs sound clear on auscultation? Is patient aware of surroundings? Are there signs of respiratory distress absent (e.g., retractions, nasal flaring, use of accessory muscles)?

### NURSING CARE PLAN for the Patient With a Burn Injury—cont’d

<tr>
<td>Intervention</td>
<td>Provide appropriate pulmonary care: turn, cough, deep breathe every 2–4 hours. <strong>Rationale</strong> Mobilizes secretions and promotes lung expansion. <strong>Evaluation</strong> Is patient receiving vigorous pulmonary care? Is it affecting outcomes?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Provide incentive spirometer every 2–4 hours.</td>
</tr>
<tr>
<td>Intervention</td>
<td>Suction frequently as needed.</td>
</tr>
<tr>
<td>Intervention</td>
<td>Obtain sputum cultures as ordered. Note amount, color, and consistency of pulmonary secretions. <strong>Rationale</strong> Carbonaceous sputum is diagnostic for smoke inhalation injury. Infection changes color, amount, and consistency of sputum. Culture and sensitivity (C&amp;S) assists in selection of appropriate antibiotic. <strong>Evaluation</strong> Is patient coughing up any sputum? Has character of sputum been reported and documented?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Administer bronchodilators and antibiotics as prescribed. <strong>Rationale</strong> Bronchodilators decrease bronchospasms and edema. Antibiotics fight infection. <strong>Evaluation</strong> Are medications given appropriately? Are they effective?</td>
</tr>
</tbody>
</table>

**Nursing Diagnosis:** *Impaired Skin Integrity* related to thermal injury as evidenced by presence of burn lesions

**Expected Outcomes:** The patient’s skin integrity will be improved as evidenced by stopping of burning process and healing of burned areas with no infection present.

**Evaluation of Outcomes:** Did burning process stop? Is burned area healed and free from infection?

<table>
<thead>
<tr>
<th>Intervention</th>
<th>Obtain history of burning agent. <strong>Rationale</strong> Provides information related to depth, duration of contact, and resistance of tissues. If fire scenario, consider possible inhalation injury. <strong>Evaluation</strong> What caused this thermal injury? How long was patient in contact with agent?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intervention</td>
<td>Assess burning process. If heat is felt on wound, cool with tepid tap water or sterile water. <strong>Rationale</strong> Depth of injury increases with length of exposure to burning agent. <strong>Evaluation</strong> Is heat felt over wounds? Has burn process been effectively stopped?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Remove clothing and jewelry. <strong>Rationale</strong> These items can retain heat and thermal agent, therefore increasing depth of injury. Jewelry can be constrictive when edema develops. <strong>Evaluation</strong> Are clothing and jewelry removed and constriction avoided?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Do not apply ice. <strong>Rationale</strong> Ice causes vasoconstriction, further increasing skin damage. Ice also causes a decrease in core body temperature, which may promote shock. <strong>Evaluation</strong> Is burning stopped without the use of ice?</td>
</tr>
</tbody>
</table>
Intervention: Cover patient with clean sheet or blanket. **Rationale**: Prevents excessive heat loss. Decreases pain from air exposure. Protects patient from environmental contamination. **Evaluation**: Is patient covered?

Intervention: For all chemical burns, initiate immediate copious tepid water lavage for 20 minutes along with simultaneous removal of contaminated clothing. Do not neutralize chemical because this takes too much time and resulting reaction may generate heat and cause further skin injury. **Rationale**: Dilution and removal of chemical agent halts burning process. Lavage dissipates heat. **Evaluation**: Has lavage been initiated?

Intervention: Brush off dry chemicals before lavage. **Rationale**: To prevent further burn damage due to reaction of dry chemical with water. **Evaluation**: Are dry chemicals removed?

Intervention: Use heavy rubber gloves or thick gauze for removal of clothing. **Rationale**: Protects health care workers from injury. **Evaluation**: Do health care workers remain safe?

Intervention: Cleanse wound at bedside or via showering. **Rationale**: Promotes healing and helps decrease infection. **Evaluation**: Is burn wound clean and free of wound debris?

Intervention: Assist registered nurse (RN) or HCP to assess the burn area for extent (percentage) and depth (partial thickness, full thickness) of injury. **Rationale**: Provides basis for triage of care. Important for calculating resuscitation fluid therapy. **Evaluation**: What is the estimation of percentage of burn injury? What is depth of injury?

Intervention: Assist RN or physician with debriding wound via surgical, chemical, or mechanical means. Apply topical agent as prescribed. **Rationale**: Promotes healing and healthy granulation bed. Most agents prevent infection and promote healing. **Evaluation**: Is eschar present? Is wound free of wound debris? Is agent applied as directed?

Intervention: Apply dressing as prescribed. **Rationale**: Dressing types vary and are influenced by area, extent, and depth of injury, as well as by topical agent used. Dressing protects burn area and promotes healing. **Evaluation**: Is dressing applied appropriately?

Intervention: Do not wrap skin surface to skin surface (e.g., wrap fingers and toes separately; donut bandage around ears). **Rationale**: Wrapping separately prevents webbing and contractures. **Evaluation**: Are skin surfaces separated? Are webbing and contractures avoided?

Intervention: Limit bulk of dressings. **Rationale**: Mobility is enhanced with less bulky dressing. **Evaluation**: Is patient’s mobility maximized?

Intervention: Wrap extremities from distal to proximal. **Rationale**: Circulation is increased when extremities are wrapped distal to proximal. **Evaluation**: Is wrapping done correctly? Is edema of distal extremity avoided?

**Nursing Diagnosis:** Deficient Fluid Volume related to evaporative losses from wound, capillary leak, and decreased fluid intake as evidenced by urine output less than 50 mL per hour, hypotension, tachycardia, weight loss

**Expected Outcomes:** The (adult) patient will maintain adequate circulating volume as evidenced by urine output of 50 mL/hr, blood pressure within normal limits, heart rate between 60 and 100 beats per minute, and stabilized body weight.

**Evaluation of Outcomes:** Is urine output maintained at least at 50 mL/hr? Are the blood pressure and heart rate within normal limits? Is patient’s weight stable?

Intervention: Obtain admission weight and monitor weight daily. **Rationale**: Helps measure fluid loss or gain. **Evaluation**: Is patient’s weight documented? Is it stable?

Intervention: Record intake and output (I&O) hourly. **Rationale**: Serves as guide for fluid loss and replacement. **Evaluation**: Is urine output adequate?
**NURSING CARE PLAN for the Patient With a Burn Injury—cont’d**

**Intervention** Examine for signs and symptoms of hypovolemia (hypotension, tachycardia, tachypnea, extreme thirst, restlessness, disorientation). **Rationale** Fluid volume loss is multifocal (e.g., through increased capillary permeability, insensible loss). **Evaluation** Does patient exhibit any signs or symptoms of hypovolemia?

**Intervention** Monitor electrolytes, complete blood count (CBC) and report abnormal results to HCP. **Rationale** Serves as guide for electrolyte replacement and blood product replacement. **Evaluation** What are patient’s lab values? Are abnormal results reported?

**Intervention** Administer or monitor IV fluids as ordered via large-bore IV catheter. **Rationale** Fluid replacement begins immediately to prevent hypovolemia. Large vessels are needed for rapid delivery of fluids. **Evaluation** Is patient’s fluid replacement adequate? Is catheter patent?

**Intervention** Insert indwelling urinary catheter. **Rationale** Accurate urine output measurement is essential for fluid replacement calculation. **Evaluation** Is catheter patent and output recorded?

**Intervention** Monitor urine for amount, specific gravity, and hemochromogens. **Rationale** Specific gravity helps predict volume replacement. Hemochromogens can cause renal tubular damage. **Evaluation** What are patient’s urine values?

**Intervention** Administer osmotic diuretics as ordered; monitor response to therapy. **Rationale** Decreased urine output can be caused by decreased renal flow (due to myoglobin in urine). **Evaluation** What is urine output? Has it changed due to therapy?

**Intervention** Assess gastrointestinal function for absence of bowel sounds. Maintain nasogastric tube as ordered. **Rationale** Splanchnic constriction due to hypovolemia can cause a paralytic ileus. **Evaluation** Are patient’s bowel sounds within normal limits? Is nasogastric tube patent?

**Nursing Diagnosis:** Pain related to burns or graft donor sites as evidenced by patient’s rating on appropriate pain scale, restlessness, sleeplessness

**Expected Outcomes:** The patient will experience pain control as evidenced by pain rating acceptable to patient and nonverbal cues, such as less restlessness and ability to rest or sleep.

**Evaluation of Outcomes:** Does patient verbalize pain control? How many hours of rest/sleep does patient have in 24 hours? Does patient state she or he feels rested?

**Intervention** Assess pain using WHAT’S UP? mnemonic. Rate pain on appropriate pain scale. **Rationale** Provides baseline to monitor response to therapy. **Evaluation** Is patient’s individual response to pain documented?

**Intervention** Observe for varied responses to acute pain: increase in blood pressure, pulse, respirations; increased restlessness and irritability; increased muscle tension; facial grimaces; guarding. **Rationale** Responses to pain are variable. These parameters change in response to pain. **Evaluation** What are patient’s responses to pain? Do responses change with treatment?

**Intervention** Acknowledge presence of pain. Explain causes of pain. **Rationale** Encourages trust and understanding. **Evaluation** Is patient more trusting of the nurse and the treatments?

**Intervention** Administer opioids as ordered. Use patient-controlled analgesia (PCA) as appropriate. **Rationale** Opioids are needed for severe burn pain. PCA allows patient more control. **Evaluation** Is patient being medicated for pain appropriately?

---

**WORD BUILDING**

**hemochromogen:** heme—iron + chrom—color + gen—to produce
NURSING CARE PLAN for the Patient With a Burn Injury—cont’d

**Intervention** Offer diversional activities (e.g., music, TV, books, games, relaxation techniques). **Rationale** Helps patient focus on something other than pain. **Evaluation** Does patient use diversional activities? Do they help?

**Intervention** Position patient for comfort in good body alignment. **Rationale** Increases comfort. **Evaluation** Is patient positioned as comfortably as possible?

**Intervention** Elevate burned extremities. **Rationale** Elevation decreases edema and pain. **Evaluation** Are extremities elevated? Is pain reduced?

**Intervention** Maintain comfortable environment (e.g., bed cradle; comfortable environmental temperature, 86–91.4°F [30–33°C]; quiet environment). **Rationale** Pressure from bed linens may cause discomfort; with loss of integument, body cannot self-regulate temperature. **Evaluation** Does patient verbalize comfort of environment?

**Nursing Diagnosis:** *Impaired Physical Mobility* related to burn healing, pain, and contractures

**Expected Outcomes:** The patient will maintain adequate physical mobility as evidenced by ability to ambulate, move in bed, and tolerate activity.

**Evaluation of Outcomes:** Is the patient able to sit? Is the patient able to get out of bed? Is the patient able to walk with or without assistance?

**Intervention** Encourage ambulation as able. **Rationale** Helps prevent atelectasis and pneumonia. **Evaluation** Is patient optimally mobilized?

**Intervention** Perform active and passive range of motion exercises on affected areas. **Rationale** Prevents contractures and hypertrophic scarring. **Evaluation** Do affected areas remain mobile?

**Intervention** Provide support above and below affected joints. Apply splints and functional devices as ordered. **Rationale** Maintains functional position of extremities. **Evaluation** Are immobilized joints in a functional position?

**Intervention** For lower extremity burns, apply bandages and elastic bandages before patient is in upright position. **Rationale** Promotes venous return and minimizes edema formation. **Evaluation** Does patient tolerate being upright? Is edema minimized?

**Nursing Diagnosis:** *Ineffective Peripheral Tissue Perfusion* related to circumferential burns, blood loss, and decreased cardiac output as evidenced by weak pulses, cool extremities, limited movement and sensation

**Expected Outcomes:** The patient will maintain adequate tissue perfusion as evidenced by presence of peripheral pulses, minimal edema, intact sensation and motion, and warm extremities.

**Evaluation of Outcomes:** Are peripheral pulses present? Are extremities warm, with adequate sensation, movement, and circulation? Is edema decreased?

**Intervention** Assess pulses on burned extremities every 15 minutes until stable, then every hour. **Rationale** If pulses diminish, an escharotomy may be indicated. **Evaluation** Are pulses present and documented?

**Intervention** Use Doppler as needed to detect weak pulses. Assess capillary refill, sensation, color, swelling, and movement. **Rationale** Assesses peripheral perfusion. **Evaluation** Is the extremity warm, with adequate color, sensation, movement, and capillary refill?

**Intervention** Monitor for numbness, tingling, and increased pain in burned extremity. **Rationale** Can be indicative of increased pressure from edema. **Evaluation** Does patient report numbness, tingling, or pain?
**NURSING CARE PLAN for the Patient With a Burn Injury—cont’d**

**Intervention** Measure circumference of burned extremities. **Rationale** Monitors edema formation. **Evaluation** Is there evidence of edema? Is it getting better or worse?

**Intervention** Report changes in assessment promptly. **Rationale** Emergency intervention may be indicated. **Evaluation** Does patient require an emergency intervention?

**Intervention** Elevate burned extremity above level of the heart. **Rationale** Enhances venous return and decreases edema formation. **Evaluation** Are all burned extremities elevated above heart level? Is edema decreasing?

**Intervention** Apply burn dressing loosely. **Rationale** Prevents constriction and allows for expansion as edema forms. **Evaluation** Is dressing limiting circulation?

**Intervention** Assist with muscle compartment pressure measurement. **Rationale** Helps determine need for escharotomy (if pressure exceeds 25 mm Hg). **Evaluation** What is patient’s pressure?

**Intervention** Assist with escharotomy as needed. **Rationale** If indicated, removal of eschar allows for edema expansion and permits peripheral perfusion. **Evaluation** Does patient require an escharotomy? Is edema relieved?

**Nursing Diagnosis:** Risk for Infection

**Expected Outcome:** The patient will not develop a wound infection or sepsis.

**Evaluation of Outcome:** Is there healthy granulation tissue on unhealed areas with no evidence of infection? Are donor sites free of infection? Have skin grafts taken? Is there absence of clinical manifestation of infection (temperature 98.6°F [37°C], normal white blood cell [WBC] count)?

**Intervention** Use sterile technique with wound care. **Rationale** The unhealed burn wound is an excellent culture medium for bacterial growth. **Evaluation** Is sterile technique used for all wound care?

**Intervention** Maintain protective isolation with careful hand hygiene. **Rationale** Prevents spread of bacteria from patient to patient or nurse to patient. **Evaluation** Do all persons in contact with patient maintain proper precautions?

**Intervention** Administer immunosupportive medications as prescribed: tetanus and gamma globulin. **Rationale** Immunoglobulins are depressed at time of severe burn injury. **Evaluation** Have medications been administered if indicated?

**Intervention** Perform wound care as prescribed, which may include the following: Inspect and débride wounds daily; culture wound three times a week or at sign of infection; shave hair at least 1 inch around burn areas if necessary (excluding eyebrows); inspect invasive line sites for inflammation (especially if line is through a burn area). **Rationale** Provides quick identification of bacterial wound invasion and decreases incidence of infection. Presence of hair increases medium for bacterial growth. **Evaluation** What does wound look like? Is it débrided? What are culture results? Does hair present a risk for infection?

**Intervention** Continually assess for and report signs and symptoms of sepsis: temperature elevation, change in sensorium, changes in vital signs and bowel sounds, decreased output, positive blood and wound cultures. **Rationale** The burn patient is at risk for sepsis until wound is healed. **Evaluation** Does patient exhibit any signs or symptoms of sepsis?

**Intervention** Administer systemic antibiotics and topical agents as prescribed. **Rationale** Antibiotics prevent or treat infection. **Evaluation** Does patient require systemic antibiotics? Are topical agents applied appropriately? Is wound healing?
SUGGESTED ANSWERS TO

CRITICAL THINKING

■ Mr. Weinberg

Superficial partial-thickness burns usually heal in 7 to 10 days. Deep partial-thickness burns may take up to 3 weeks. All of this depends on the location of the injury, the health of the patient, and if he remains infection free.

■ Mrs. Rivera

1. Mrs. Rivera has an inhalation injury. This takes precedence over the burn and other injuries.
2. 

\[
\frac{1 \text{ L}}{6 \text{ hr}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 167 \text{ mL/hr}
\]

■ Mrs. Potter

The burned and graft areas will be sensitive to sunlight for up to 1 year. These areas should be covered, and she needs to use sunscreen anytime she is out in the sun. Her physician should offer guidance as to whether any exposure is safe, and if so, what type of sunscreen agent is recommended. In addition, if any areas are not completely healed, she will be at risk for infection.

REVIEW QUESTIONS

1. A patient is brought to the emergency department after a house fire. The patient has extensive trunk and lower extremity burns, and is diagnosed with a deep partial thickness burn. What assessment findings does the nurse expect?

   1. Snowy white, painless lesions
   2. Blistered, pinkish white, painful lesions
   3. Blackened, painful lesions
   4. Bright red, moist lesions

2. Which of the following actions is appropriate initial treatment of a chemical burn?

   1. Lavage with water.
   2. Neutralize the chemical.
   3. Apply the prescribed topical agent.
   4. Wrap the patient in sterile sheets.

3. A patient is admitted to the emergency department with flame burns to the entire chest, abdomen, back, and upper extremities. Using the Rule of Nines, what approximate percentage of burns should the nurse document?

   1. 36%
   2. 45%
   3. 54%
   4. 64%

4. Which nursing interventions are appropriate for a patient with a circumferential burn to an extremity? Select all that apply.

   1. Apply compression bandages starting at the distal end of the extremity.
   2. Administer analgesics if numbness or tingling occur.
   3. Check neurovascular status hourly.
   4. Assist with escharotomy if indicated.
   5. Elevate the extremity.

5. How will the nurse know if interventions for impaired gas exchange related to smoke inhalation have been effective?

   1. PaCO₂ is greater than 45 mm Hg.
   2. Spo₂ is less than 90%.
   3. pH is 7.34.
   4. Pao₂ is 88 mm Hg.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Define mental health and mental illness.
2. Describe the components of a mental health status assessment.
3. Describe the Diagnostic and Statistical Manual of Mental Disorders (5th ed., DSM-5) as a tool to diagnose mental illness.
4. Identify common ego defense mechanisms.
5. Describe characteristics of a therapeutic milieu.
6. Explain how psychoanalysis, behavior management, cognitive behavioral therapy, counseling, group therapy, electroconvulsive therapy, and relaxation therapy are carried out.
7. Describe the role of the licensed practical nurse/licensed vocational nurse (LPN/LVN) in mental health nursing.
When studying mental illnesses, it is important to review and understand the anatomy and physiology of the brain and central nervous system (CNS). The brain is involved in thinking, decision making, speaking, emotion, memory, motor and sensory activity, and the basic functions of temperature regulation and breathing, as well as many other functions. Refer to Chapter 47 to review the nerves, structure of neurons, synapses, neurotransmitters, and the autonomic nervous system, as well as the structure and function of the brain. Also see Table 56.1 for the hypothesized roles of CNS neurotransmitters in mental illness.

Opinions within the mental health community differ as to what mental health and mental illness are. Mental health has been defined in many ways. These definitions include the ability to do the following:

- Be flexible.
- Take responsibility for own actions.
- Form close relationships.
- Make appropriate judgments.
- Solve problems.
- Cope with daily stress.
- Have a positive sense of self.

ANS = autonomic nervous system; CNS = central nervous system.

Mental illness can be defined as experiencing the following:

- Impaired ability to think
- Impaired ability to feel
- Impaired ability to make sound judgments
- Impaired ability to adapt
- Difficulty in coping or inability to cope with reality

- Difficulty in forming or inability to form strong personal relationships.

It is important to remember that mental health and mental illness exist on a continuum. It is natural for emotions to ebb and flow from day to day in response to the degree of stress experienced. People who remain mentally healthy are able to...
cope with and keep their stress in perspective. Others are not able to do so and over time may develop physical or emotional illnesses as a result of present and past life stresses.

Picture the seesaw that children play on. Mental health and mental illness are like a seesaw. When children of approximately equal weight get on each end of the seesaw, they can balance each other and keep the seesaw even. Mentally healthy people can stay in a state of emotional balance. Sometimes one child weighs just a little more than the other and the seesaw tips just a little to one side. Mentally healthy people can cope with this fluctuation. Sometimes another child gets on or one child greatly outweighs the other, and the seesaw gets out of balance completely; one end goes way up while the other goes way down, and it stays there until someone alters the balance. When a person’s moods are way down or way up, he or she is not in emotional homeostasis (balance).

**Etiologies**

The line between the causes of mental illnesses and other brain or neurological disorders is being erased as we learn more about how the brain functions. As scientists study the brains of people who have mental illnesses, they are concluding that mental illness has a biological basis. Changes in the brain’s structure, chemistry, and function are associated with expressions of mental illness. However, it is important to note that while mental illnesses can be categorized as brain diseases, not all brain diseases are mental illnesses.

Explanations of mental illness in this unit include concepts from the psychological and the psychobiological (or biological) theories. When pertinent, other theories (e.g., behavioral, environmental) are also presented. Most mental illnesses have no identifiable cause. Some etiological theories have stronger positive correlations to illnesses than others. When appropriate, this unit gives the most current or most widely accepted view of an etiology.

**Social and Cultural Environments**

Many professionals in the field of behavioral health believe that social and cultural environments have a great influence on the way people develop and process life experiences. Some behavioral health clinicians believe that some cultural traditions and beliefs cause disturbances in personal relationships, which can lead to forms of emotional disturbance. It is part of the nurse’s role to take time to learn about traits that are common among people and traits that differ. Although understanding that each person is a unique individual, it is important to have an understanding of broad customs and beliefs to avoid unrealistic expectations of patients.

**Spirituality and Religion**

Spirituality and religion are extremely important to some patients and unimportant to others. A person’s success in recuperating from physical or emotional illness may be deeply tied to spirituality. It is necessary to be comfortable talking to the patient about spiritual needs while being careful not to impose personal values on the patient. If you are not comfortable in these situations, you should offer to call the spiritual or religious leader of the patient’s choice.

For more information about mental health and illness, visit the National Institute of Mental Health at www.nimh.nih.gov, the American Psychiatric Association at www.psych.org, the American Psychological Association at www.apa.org, the American Psychiatric Nurses Association at www.apna.org, or the International Society of Psychiatric-Mental Health Nurses at www.ispn-psych.org.

**NURSING ASSESSMENT OF MENTAL HEALTH**

During the assessment phase of the nursing process, a mental status examination is performed. This is a series of questions, activities, and observations that evaluate eight areas:

- Appearance and behavior
- Level of awareness and reality orientation
- Thinking/content of thought
- Memory
- Speech and ability to communicate
- Mood and affect
- Judgment
- Perception

A number of tools of varying names, lengths, and formats are used to evaluate mental capabilities. See Table 56.2 for a sample mental status examination.

After data have been collected, the LPN/LVN collaborates with the registered nurse (RN) to develop nursing diagnoses (Box 56-1).

**DIAGNOSTIC TESTS**

Physicians use a variety of diagnostic criteria to diagnose mental illness. It is important to rule out physical illness as a cause of symptoms. A primary care provider may choose to refer a patient to a psychiatrist or other mental health professional for further testing and diagnosis.

The diagnostic tool that is used most widely by psychiatrists and other mental health professionals is the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, or DSM-5 (American Psychiatric Association, 2013). The DSM-5 groups illnesses into categories of clinical disorders. This is a complex diagnostic tool. Although as an LPN you will not be responsible for completing the assessment or making a diagnosis, you can contribute valuable information.

There are also batteries of psychological tests that can be administered and interpreted by psychiatrists, psychologists, social workers, or advanced practice nurses. Age, hand tremors, vision, language barriers, educational background, and the interpretation of the health care provider are some factors that can influence the results of these tests.
### TABLE 56.2  SAMPLE MENTAL STATUS EXAMINATION

<table>
<thead>
<tr>
<th>Area to Be Examined</th>
<th>Type of Examination</th>
<th>Normal Parameters</th>
<th>Alterations from Normal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Appearance and behavior</td>
<td>Observations about dress, hygiene, posture, and appearance and about the patient’s actions and reactions to health care personnel.</td>
<td>Clean, combed hair. Clothing intact and appropriate to weather or situation. Teeth/dentures in good repair. Posture erect. Cooperates with health care personnel.</td>
<td>Displays either unusual apathy or concern about appearance. Displays uncooperative, hostile, or suspicious behaviors toward health care personnel.</td>
</tr>
<tr>
<td>Level of awareness and orientation</td>
<td>Subjective and objective assessment of patient’s degree of alertness (wakefulness) and degree of patient’s knowledge of self.</td>
<td>Awareness is measured on a continuum that ranges from unconscious to manic. “Normal alertness” is the desired behavior. Facilities may provide a standard format for this assessment, but observations can be documented as well if the patient is not able to stay awake for even short intervals or if the patient is overly active and has difficulty staying in one place. Orientation is assessed by asking the patient questions relating to person, place, and time, such as “Who is this sitting next to you?” “Where are you right now?” or “What year is it?”</td>
<td>Outcome is not considered within accepted normal limits if the patient is difficult to arouse and keep awake or if the patient has difficulty feeling calm. Abnormal results of orientation are the patient’s inability to correctly answer orientation questions or inability to answer commonly known questions, such as “Who is the president?”</td>
</tr>
<tr>
<td>Thinking/content of thought</td>
<td>Subjective assessment of what the patient is thinking and the process the patient uses in his or her thinking.</td>
<td>Formal testing may be done by a psychologist or psychiatrist to determine the patient’s general thought content and pattern. Nurses may contribute to the assessment of thought by documenting statements the patient makes regarding daily care and routines.</td>
<td>Abnormal behaviors include flight of ideas, loose associations, phobias, delusions, and obsessions.</td>
</tr>
<tr>
<td>Memory</td>
<td>Subjective assessment of the mind’s ability to recall recent and remote (long-term) information.</td>
<td>Recent memory: recall of events that are immediately past or within 2 weeks before the assessment, such as a recent news event. One measurement technique is to ask the patient what they had for breakfast that day or what they did yesterday afternoon. Remote memory: recall of events of the past beyond 2 weeks before assessment. Patients may be asked where they were born, where they went to grade school, etc.</td>
<td>Inability to accurately perform recent or remote (long-term) recall exercises within parameters. May indicate symptom of delirium or dementia.</td>
</tr>
</tbody>
</table>
### TABLE 56.2 SAMPLE MENTAL STATUS EXAMINATION—cont’d

<table>
<thead>
<tr>
<th>Area to Be Examined</th>
<th>Type of Examination</th>
<th>Normal Parameters</th>
<th>Alterations from Normal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Speech and ability to communicate</td>
<td>Objective and subjective assessment of how the patient uses verbal and nonverbal communication. Stuttering, repetition of words, and words that the patient makes up (neologisms) are also assessed.</td>
<td>Patient can coherently produce words appropriate to age, education, and life experience. Rate of speech reflects other psychomotor activity (e.g., faster if the patient is agitated). Volume is not too soft or too loud. Speech is fluid and appropriate.</td>
<td>Limited speech production. Rate of speech is inconsistent with other psychomotor activity. Volume is not appropriate to situation (speaks louder or softer than appropriate). Presence of stuttering, word repetition, or neologisms may indicate physical or psychological illness.</td>
</tr>
<tr>
<td>Mood and affect</td>
<td>Objective and subjective assessment of the patient’s stated feelings and emotions. Affect measures the outward expression of those feelings.</td>
<td>Mood is the stated emotional condition of the patient and should reflect situations as they occur. Facial expression and body language (affect) should match (be congruent with) the stated mood. Affect should change to fluctuate with the changes in mood.</td>
<td>Mood and affect do not match (e.g., facial expression does not appear sad while the patient is expressing sad feelings).</td>
</tr>
<tr>
<td>Judgment</td>
<td>Subjective assessment of a patient’s ability to make appropriate decisions about his or her situation or to understand concepts.</td>
<td>When given a proverb or situation to solve, such as “You can’t teach an old dog new tricks,” the patient should be able to give some sort of acceptable interpretation, such as, “Old habits are hard to break” or “It is hard to learn something new.”</td>
<td>Patient cannot interpret the sayings or complete problem-solving questions appropriately. The patient might answer very literally, “Dogs can’t learn anything when they get old.”</td>
</tr>
<tr>
<td>Perception</td>
<td>Assessment of the way a person experiences reality. Observation of the patient’s statements about his or her environment and the behaviors expressed in association with those statements. Assessment of the patient’s insight into his or her condition.</td>
<td>All five senses are monitored for the patient’s perception of reality. Perceptions of environment are accurate. Insight into condition is appropriate.</td>
<td>Hallucinations may occur with schizophrenia. Hallucinations are false sensory perceptions. Illusions are misperceptions of reality. Patient unable to state understanding of the origin of the illness; associated behaviors inappropriate. Many people with schizophrenia or mania have poor insight because of impairment of prefrontal cortex functioning during psychosis.</td>
</tr>

</table>
**Distinguishing Physical Versus Mental Health Disorders**

Some physical disorders can mimic mental health disorders, so diagnostic tests may be performed to either confirm or rule out a diagnosis of a mental illness:

- **Laboratory tests** can rule out problems such as electrolyte imbalances, hypothyroidism, infections, dehydration, drug toxicity, or pregnancy.
- **Computed tomography (CT) scans or magnetic resonance imaging (MRI)** can rule out tumors, lesions, or other physical problems.
- **Positron emission tomography (PET) scans** can identify how the parts of the brain are functioning by showing chemical activity or metabolism.

**COPING AND EGO DEFENSE MECHANISMS**

“Oh, just learn to cope with it.” “Get a grip.” “Don’t make a mountain out of a molehill.” These are pieces of advice that people may have heard or given at some point. But what do they mean? What is coping? Coping is the way one adapts psychologically, physically, and behaviorally to a stressor.

People have different methods of coping or dealing with their stressors. Culture, religion, individual belief systems, experience, and personal choice influence a person’s responses to stress. It is not the value of a behavior that we assess as nurses; it is the desired outcome that is important. What is an effective coping skill? Is it healthy? Does it work? How do we as nurses observe and measure it?

**Effective Coping Skills**

Effective coping skills offer healthy choices for dealing with stressors. Effective coping skills are also conscious mechanisms. Hospitalization is stressful for patients and families. Many things are unknown and unfamiliar. The patient may not understand the illness or the implications of the treatment plan. It is common for patients to use coping mechanisms during hospitalization. The process of effective coping is sometimes called adaptation. Allowing the patient to practice new coping techniques will give him or her confidence and will decrease the stress that can accompany change.

Often the dividing line between effective and ineffective coping is the frequency of its use. For instance, mild anxiety can be positive. Generally, when there is a little anxiety, people are more alert and ready to respond. The fight-or-flight mechanism can actually help one adapt to a new situation. However, too much anxiety be gins to cloud the consciousness and interfere with the ability to make appropriate choices and to recall new adaptive tools that have been learned. One of the most helpful roles you can perform is to listen to the patient’s thoughts and feelings about the stressor, assist him or her in identifying precipitating factors and patterns to the patient’s stress, encourage the patient to problem solve, and provide assistance to develop alternative solutions to a problem.
Ineffective Coping Skills

Sometimes coping behaviors are ineffective. When conscious techniques are not successful, people may unconsciously fall into habits that give the illusion of coping. These habits are called ego defense mechanisms (or coping or mental mechanisms). Ego defense mechanisms act as mental pressure valves. The purpose of ego defense mechanisms is to reduce or eliminate anxiety. They give the impression that they are helping alleviate the stress level. When used in very small doses, ego defense mechanisms can be helpful. When they are overused or are the only means used to deal with anxiety, they can become ineffective and unhealthy. People are not born with these coping behaviors; they are learned as responses to stress. Many times they develop by age 10. They may appear to be conscious, but they are, for the most part, unconscious mechanisms. Some commonly used ego defense mechanisms are listed in Table 56.3.

### TABLE 56.3 EGO DEFENSE MECHANISMS

<table>
<thead>
<tr>
<th>Mechanism</th>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Denial</td>
<td>Usually the first defense learned and used. Unconscious refusal to see reality; not conscious lying.</td>
<td>The alcoholic states, “I can quit any time I want to.”</td>
</tr>
<tr>
<td>Repression (stuffing)</td>
<td>An unconscious “burying” or “forgetting” mechanism. Excludes or withholds from consciousness events or situations that are unbearable.</td>
<td>A step deeper than “denial.” A patient may “forget” about an appointment he or she does not want to keep.</td>
</tr>
</tbody>
</table>
| Rationalization| Using a logical-sounding excuse to cover up true thoughts and feelings. The most frequently used defense mechanism. | 1. “I made a medication error because the doctor’s orders were confusing.”  
2. “I failed the test because the teacher wasn’t clear about what would be on it.” |
| Compensation   | Making up for something perceived as an inadequacy by developing some other desirable trait. | 1. The small boy who wants to be a basketball center instead becomes an honor roll student.  
2. The physically unattractive person who wants to model instead becomes a famous designer. |
TABLE 56.3  EGO DEFENSE MECHANISMS—cont’d

<table>
<thead>
<tr>

<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reaction formation (overcompensation)</td>
<td>Similar to compensation, except the person usually develops the exact opposite trait.</td>
<td>1. The small boy who wants to be a basketball center becomes a political voice to decrease the emphasis on sports in the elementary grades. 2. The physically unattractive person who wants to be a model speaks out for eliminating beauty pageants.</td>
</tr>
<tr>
<td>Regression</td>
<td>Emotionally returning to an earlier time in life when the patient experienced far less stress. Commonly seen in patients while hospitalized. NOTE: People do not go back to the same developmental age. This is highly individualized.</td>
<td>1. Children who are toilet trained begin to wet the bed after the birth of a younger sibling. 2. Adults start crying and have a “temper tantrum.”</td>
</tr>
<tr>
<td>Projection</td>
<td>Ascribing one’s own unacceptable qualities or feelings to someone else. May lead to scapegoating.</td>
<td>1. A patient might state: “My sister is so jealous of me,” when actually the patient is jealous of her sister. 2. An anxious patient may say to the nurse, “Why do I make you so nervous?”</td>
</tr>
<tr>
<td>Displacement (transference)</td>
<td>“Kick-the-dog syndrome.” Transferring anger and hostility to another person or object that is perceived to be less powerful than oneself.</td>
<td>Parent loses job without notice; goes home and verbally abuses spouse, who unjustly punishes child, who slaps the dog.</td>
</tr>
<tr>
<td>Restitution (undoing)</td>
<td>Make amends for a behavior one thinks is unacceptable. Makes an attempt at reducing guilt.</td>
<td>1. A person gives a treat to a child who is being punished for a wrongdoing. 2. The person who sees someone lose a wallet with a large amount of cash does not return the wallet, but puts extra in the collection plate at the next church service.</td>
</tr>
<tr>
<td>Conversion reaction</td>
<td>Anxiety is channeled into physical symptoms. Often the symptoms disappear soon after the threat is over.</td>
<td>Nausea develops the night before a major exam, causing the person to miss the exam. Nausea may disappear soon after the scheduled test is finished.</td>
</tr>
<tr>
<td>Avoidance</td>
<td>Unconsciously staying away from events or situations that might cause feelings of aggression or anxiety.</td>
<td>“I can’t go to the class reunion tonight. I’m just so tired, I have to sleep.”</td>
</tr>
</tbody>
</table>

**Therapeutic Communication**

Many people take communication for granted. In the mental health setting, communication is a tool used to relate therapeutically with patients. It is important to be intentional about the messages we communicate to patients. Therapeutic communication is accomplished through the deliberate use of verbal and nonverbal techniques. Other areas to consider when communicating are the patient’s personal values, attitudes, beliefs, culture, religion, social status, gender, and age or developmental level.

Verbal therapeutic communication techniques can help facilitate an interpersonal interaction. For instance, if you ask a patient to explain something to you in more detail, you are using the therapeutic communication technique of exploring. Verbal communication is also influenced by the tone, pitch, speed, and volume of speech. Some commonly used therapeutic communication techniques are listed in Table 56.4.

<tbody>
<tr>
<td>Encouraging descriptions of perceptions</td>
<td>Asking the patient what he or she is seeing or hearing</td>
<td>“Tell me what the voices are saying to you.”</td>
</tr>
<tr>
<td>Encouraging comparison</td>
<td>Asking the patient to compare similarities or differences</td>
<td>“How is this medication working for you compared to the last time you used it?”</td>
</tr>
<tr>
<td>Exploring</td>
<td>Looking deeper into a subject, idea, or experience</td>
<td>“Tell me more about the last time you were depressed.”</td>
</tr>
<tr>
<td>Focusing</td>
<td>Concentrating on a single idea or event</td>
<td>“Tell me more about how your divorce made you feel.”</td>
</tr>
<tr>
<td>Formulating a plan of action</td>
<td>Assisting the patient to come up with a plan to cope with stress</td>
<td>“When this happens in the future, how could you handle it more constructively?”</td>
</tr>
<tr>
<td>Giving broad openings</td>
<td>Allowing the patient to steer the interaction</td>
<td>“What would you like to work on today?”</td>
</tr>
<tr>
<td>Giving recognition</td>
<td>Acknowledging or showing awareness</td>
<td>“I see you went to your therapy group today.”</td>
</tr>
<tr>
<td>Making observations</td>
<td>Verbalizing what is observed</td>
<td>“I notice you seemed upset after your visit.”</td>
</tr>
<tr>
<td>Offering self</td>
<td>Extending one’s presence</td>
<td>“I am available to talk whenever you would like.”</td>
</tr>
<tr>
<td>Offering general leads</td>
<td>Giving the patient encouragement to continue</td>
<td>“I see…” “Go on…”</td>
</tr>
<tr>
<td>Placing event in time or sequence</td>
<td>Clarification of events in time</td>
<td>“Was this before or after your first hospitalization?”</td>
</tr>
<tr>
<td>Presenting reality</td>
<td>Defining reality in simple terms</td>
<td>“The voices may seem real to you, but they are a symptom of your illness.”</td>
</tr>
<tr>
<td>Restating</td>
<td>Repeating the main idea of what the patient has verbalized</td>
<td>“It sounds as if you are feeling frustrated.”</td>
</tr>
<tr>
<td>Reflecting</td>
<td>Statements, questions, or feelings are referred back to the patient</td>
<td>“What do you think you should do?”</td>
</tr>
<tr>
<td>Seeking clarification</td>
<td>Searching for understanding of what was said</td>
<td>“Tell me if this is what you meant when you said…”</td>
</tr>
<tr>
<td>Verbalizing the implied</td>
<td>Putting into words what the patient has implied or said indirectly</td>
<td>“You must be feeling very sad right now.”</td>
</tr>
<tr>
<td>Using silence</td>
<td>Gives both the nurse and the patient a chance to collect their thoughts and organize what they are going to say</td>
<td></td>
</tr>
</tbody>
</table>

Components of nonverbal communication include physical appearance, dress, body movement and posture, touch, facial expression, and eye contact. It is believed that most communication takes place nonverbally, so it is possible that while you are saying one thing to a patient, your body language could be saying something else.

There are also barriers to effective communication that are commonly called communication blocks. A nurse who tells a patient “Don’t worry, everything will be all right” has just given the patient false reassurance. This barrier communicates to the patient that his or her concerns are not being taken seriously. Some common communication blocks are listed in Table 56.5.
Milieu

One area over which you can have some control is the therapeutic environment. In the mental health setting, this therapeutic environment is called the **milieu** or therapeutic milieu. It is believed that environment has an effect on behavior. Milieu therapy is the systematic management of the social environment as a treatment modality.

A therapeutic milieu is an environment that provides containment, support, structure, involvement, and validation during the patient’s stay. The goals of milieu therapy are resocialization, ego development, and prevention of regression. Resocialization occurs when patients help govern the running of the unit and attend regular meetings to set rules and assign tasks. Ego development is fostered with structured activities that are provided to assist the patient to learn coping and social skills. Regression is discouraged when patients help with washing dishes or other small jobs that foster independence. Common milieu interventions include role modeling, positive reinforcement, a schedule of events, consistent expectations and rules for behavior, and unit meetings. Milieu therapy is difficult in this era of managed care because of shorter hospital stays.

**Psychopharmacology**

**Psychopharmacology** is the use of medications to treat psychological disorders. Since the introduction of the phenothiazine class of drugs in the 1950s (e.g., chlorpromazine), the number of medications available for treating mental health disorders has increased greatly, with newer medications having fewer side effects. The reason for using medications is twofold: First, the medications manage the symptoms, helping the patient feel more comfortable emotionally. Second, the patient is generally more receptive and able to focus on other types of therapy if medications are effective. More information on psychoactive drugs is provided in Chapter 57.

**Psychotherapies**

**Psychotherapy** is the term used to describe the form of treatment chosen by the psychologist, psychiatrist, social worker, or advanced practice mental health nurse. The goals of psychotherapy include the following:

- Reduce the patient’s emotional discomfort.
- Increase the level of the patient’s social functioning.
- Increase the ability of the patient to behave or perform in a manner appropriate to the situation.

Several specific types of therapy that are typically used are described next.

**Table 56.5 Communication Blocks**

<table>
<thead>
<tr>
<th>Mechanism</th>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agreeing/disagreeing</td>
<td>Implies that the patient’s ideas or feelings are somehow right or wrong</td>
<td>“That is right on target. I agree 100%.”</td>
</tr>
<tr>
<td>Asking “why” questions</td>
<td>Asking why implies that the patient knows the reason for his or her behavior and feelings</td>
<td>“Why were you feeling so angry?”</td>
</tr>
<tr>
<td>Changing the subject</td>
<td>Changing the subject takes control of the conversation away from the patient</td>
<td>Patient: “I am feeling so hopeless.” Nurse: “Did you go to group therapy today?”</td>
</tr>
<tr>
<td>Giving advice</td>
<td>Telling the patient what to do implies that the nurse knows what is best</td>
<td>“I think you should . . .”</td>
</tr>
<tr>
<td>Giving approval or disapproval</td>
<td>Passes judgment on the patient’s ideas or opinions</td>
<td>“That’s right.”</td>
</tr>
<tr>
<td>Giving false reassurance</td>
<td>Devalues the patient’s feelings</td>
<td>“Everything will be all right.”</td>
</tr>
<tr>
<td>Self-focusing behavior</td>
<td>The nurse focuses on his or her own feelings at the expense of the patient’s</td>
<td>“That happened to me once . . . let me tell you about it.”</td>
</tr>
<tr>
<td>Double-bind messages</td>
<td>When the nonverbal message doesn’t match the verbal message</td>
<td>“I’m listening,” as the nurse fidgets in her chair, doesn’t make eye contact, and then coughs.</td>
</tr>
</tbody>
</table>

**Word Building**

- **psychopharmacology**: psycho—soul or mind + pharmaco—drug or medicine + ology—study of
- **psychotherapy**: psycho—soul or mind + therapy—treatment
Psychodynamic Therapy

Psychodynamic therapy is based on psychoanalysis and consists of clarifying the meaning of events, feelings, and behavior and thereby gaining insight into them. Psychoanalysis was developed from Sigmund Freud’s psychoanalytic theory. Freud believed that anxiety was the primary motivation for behavior and therefore all behavior had meaning. The role of the patient is to provide the therapist with clues to the unconscious source of problems and to try to develop insights into behavior. The role of the therapist is to uncover these unconscious experiences and interpret their meanings to the patient. Some believe that psychodynamic therapies will lose popularity as we gain a better understanding of the role of the brain, neurotransmitters, and genetics in mental health.

Behavior Management

Behavior management (also called behavior modification) is a treatment method that stems from the studies of behavioral theorists such as Skinner and Pavlov. It is a common treatment modality used in long-term care facilities, with children and adolescents, and with individuals who have a low level of cognitive functioning.

According to behavior management theory, all behavior is learned, so it can be unlearned. The belief is that behavior can be changed by either positive or negative reinforcement. Positive reinforcement is the act of rewarding the patient with something pleasant when the desired behavior has been performed. For instance, if a patient has the habit of using foul language in an attempt to have a need met, the desired behavior change might be to come to a staff member and ask appropriately for what he or she needs. If this patient loves to be outside but is not allowed out except at supervised times, then a suitable positive reinforcement for her might be to allow 15 more minutes outdoors when the desired behavior is exhibited.

Negative reinforcement is the act of responding to the undesired behavior by taking a privilege or adding a responsibility. Negative reinforcement can be misinterpreted as punishment. Parents who “ground” their children for unacceptable behavior are using negative reinforcement; requiring the child to perform extra household tasks for a stated period is reinforcing the fact that the behavior has consequences. The child may not repeat the undesired behavior after negative reinforcement has been used. It is necessary to be careful to avoid violating the Patient’s Bill of Rights when performing behavior management with patients. A signed consent from the patient is advised when using this form of therapy.

The patient must understand the consequences of the behavior to be changed and the purpose for the type of consequence that is chosen. If the person is not capable of understanding the situation or is not able to remember the consequences, behavior management may not be the best form of treatment.

Cognitive Behavioral Therapy

Jean Piaget and Aaron T. Beck are cognitive theorists who have greatly contributed to modern cognitive behavioral therapy. Cognitive behavioral therapists believe that people experience mental illness due to cognitive distortions about their situations. Cognitive behavioral therapy stresses ways of rethinking situations. The therapist confronts the patient with certain distortions of thinking and then works out ways of thinking about them differently. This type of treatment is used frequently for affective or mood disorders.

Feeling sad about an unpleasant experience (such as the death of a loved one) is acceptable and normal, but long-term depression about the death is an extreme emotion and therefore considered to be unhealthy. In this situation, the patient might be helped to see the death as a sad loss. Behavioral techniques are also often used with phobias or panic disorders, in which fear may interfere with reasoning.

Cognitive therapies are gaining in popularity because they are usually significantly shorter term than other types of therapy and therefore less costly to the patient. Patients are given “homework” that is specific to their needs; they practice their assignments between sessions. Cognitive behavioral therapy in combination with medications can provide effective treatment for depression.
Counseling
Counseling is the provision of help or guidance by a health care professional. The profession of counseling is licensed and regulated differently by state and sometimes also by municipality. Nurses prepared at an LPN/LVN level or at an RN level, in some areas and with special advanced education, can practice some forms of counseling.

You may be asked or expected to accompany patients to counseling sessions or even to facilitate a group discussion. Remember that these are confidential sessions, even if they are group oriented. Patients are there to work; others are there by invitation for special reasons.

Group Therapy
Therapy groups are formed for many reasons; they can be ongoing or short term depending on the needs of the patients or the type of disorder. Group therapy is a cost-effective means of providing treatment. For example, Alcoholics Anonymous (AA) and similar 12-step self-help groups are well-established, ongoing groups formed around treatment of a specific problem. Family counseling sessions may occur with individual therapists with a specialty in the problem area for that family. Marriage counseling may be done in a group with other couples. Many times, peer counselors are used.

Therapists and counselors are tools, or facilitators, in the therapeutic process. Patients must take the suggestions given by the therapist, try them, and see what works for them. You can help by reinforcing the good work patients do to learn to stay mentally healthy and develop more effective life skills.

Electroconvulsive Therapy
Electroconvulsive therapy (ECT) is a form of treatment that is used for severely depressed patients who have not responded to psychotropic medications. ECT passes an electric current through the brain to produce a tonic-clonic (grand mal) seizure. Most mental health professionals believe ECT stimulates an increase in circulating levels of the neurotransmitters serotonin, norepinephrine, and dopamine in the brain. In essence, ECT affects neurotransmitter activity much like antidepressant medications. ECT may be frightening to patients; it is important for the nurse to provide education and information to the patient and family. Many changes have been made in this form of therapy since the 1940s, and ECT is currently a safe and effective treatment for resistant depression.

Procedure
ECT often takes place in the recovery room of an operating suite, where there is ready access to emergency equipment. Informed consent must be obtained by the physician. About 30 minutes before the procedure, the patient is given a medication to dry secretions and counteract stimulation of the vagus nerve, which can cause bradycardia and syncope. Patients are given a short-acting anesthetic before the treatment and a smooth muscle relaxant to minimize injury. Before giving the muscle relaxant, a blood pressure cuff is placed on one of the patient’s lower limbs and inflated. This is to ensure that the seizure activity can be visually monitored in this limb. Blood pressure and pulse are carefully monitored before and after the treatment. The patient is oxygenated with pure oxygen during and after the seizure until spontaneous respirations return. During treatment, an electrical stimulus is delivered to the brain via unilateral or bilateral electrodes. The amount of electrical energy used is individualized to the patient. The seizure must last at least 30 seconds to be effective. The seizure activity is monitored with an electroencephalogram (EEG) and also in the cuffed limb.

Side Effects
Side effects of ECT can be unpleasant but are usually temporary. The patient may feel confused and get forgetful immediately after the treatment. This can be from a combination of the ECT itself and the medication that was used before the treatment. If the seizure was severe, the patient may have some muscle soreness.

ECT is not used indiscriminately. It is used when other therapies have not been helpful and is usually reserved for treatment-resistant depression (see “Patient-Centered Care”).

Patient Perspective
A Daughter’s Thoughts on ECT
My mom is 83 years old and has had a total of 35 ECT treatments for severe depression in her lifetime. If you met her, you’d never know; you’d find her delightful. She’s a sweet little plump German lady with a big heart. I am a nurse, and when I tell fellow nurses about my mom, they often ask me why I didn’t get her on antidepressants. I want to scream, “How dumb do you think I am?!” Of course Mom is on antidepressants. But at intervals they don’t work and she sinks into severe depression. My choice then is to help her have ECT or let her stay depressed and miserable and put her in a nursing home. And she would soon die because when she is depressed, she refuses to move, doesn’t sleep, and is horribly miserable.

The first time my mom was scheduled for ECT, one of the nurses in our local community hospital told her to refuse it, that no one should have to go through that. It was a cruel thing to do. My mom doesn’t do well in counseling—she doesn’t believe in it. In her mind you don’t talk about your “dirty linen.” My mom was in an abusive relationship with my father for 47 years, and she hid all the problems away and doesn’t talk about them to this day. I’m so grateful to have my mom doing okay and grateful that ECT treatments exist. With ECT my mother is doing well and enjoying life. Without treatment, she would be gone. Please understand that there are times when ECT treatments are the best thing for severely depressed people, when other treatments have been ineffective.
Nursing Care

The patient should receive nothing by mouth (NPO) for at least 4 hours before a treatment. Remind the patient to empty his or her bladder and to remove dentures, contact lenses, hairpins, and other items on the body. Following ECT, carefully monitor vital signs and document the patient’s subjective and objective responses to the treatment. Stay with the patient until he or she is oriented and able to care for him or herself. Withhold oral medications and food until the gag reflex returns. Ensure that the patient is kept safe after ECT therapy.

Relaxation Therapy

A variety of relaxation techniques can be taught to help patients manage their responses to stress. Relaxation exercises such as deep, rhythmic breathing can increase oxygenation and provide distraction from stressors. Breathing exercises may be coupled with progressive muscle relaxation exercises. For this technique, patients are taught to start at the head and neck and systematically tense and then relax muscle groups as they progress toward the lower extremities. Soft music may enhance the patient’s ability to fully relax.

Imagery is the use of the imagination to promote relaxation. For this technique, the patient is taught to imagine a pleasurable experience from his or her past, such as lying on a beach or soaking in a warm bath. Use of all senses is encouraged—for a beach image, the patient might see a beach, feel the warm sun, smell salt air, and hear waves crashing against the shore. The patient might also be taught to visualize being successful in a problem situation.

Relaxation techniques may be used individually, but they are often used in combination with each other or with other therapies for maximum effect. See Chapter 5 for more information on relaxation and imagery.

Home Health Hints

Assess the patient and the patient’s home for safety issues:
- Risk of falls (especially if the patient is experiencing orthostatic hypotension from medications)
- Suicide ideation, plan, and means or access to pill stashes, weapons, or other dangerous items
- Ability to access medications, missed doses, or overdoses
- Need for additional services for activities of daily living (ADLs), such as housekeeping, medication assistance, or safety rails

SUGGESTED ANSWERS TO CRITICAL THINKING

Mr. Joseph

Different people cope in different ways. This may be a healthy way to cope in this grieving husband’s culture. Gently guide him to a room where he can express his emotions without disturbing others. Ask if he would like you to contact someone to come help support him. Document objectively: “Patient’s husband weeping loudly; guided to consultation room for privacy.”

As an LPN, your best course of action may be to report the RN’s comment objectively to your supervisor.

Mrs. Beison

Mrs. Beison is overusing the ego defense mechanism denial to cope with her cancer diagnosis. Although at times denial can be an effective coping mechanism, if Mrs. Beison continues to deny her disease and refuse treatment, her life will be in danger. You can help Mrs. Beison verbalize her fears about cancer and cancer treatment and can provide accurate information to help her make wise choices. If needed, a psychiatric evaluation can be requested. If she is found to be mentally competent, then her wishes must be respected.

REVIEW QUESTIONS

1. Which patient behavior requires additional mental health assessment?
   1. Patient is always happy and smiling.
   2. Patient can verbalize emotions.
   3. Patient is able to cope with bad news.
   4. Patient maintains some close, personal relationships.

2. Which data are important to collect during a mental health assessment? Select all that apply.
   1. Orientation to reality
   2. Mobility
   3. Ability to communicate clearly
   4. Heart sounds
   5. Memory
   6. Appearance
3. A patient being evaluated for depression asks why blood must be drawn. Which response by the nurse is best?
   1. “Your physical illnesses must be under control before your depression can be treated effectively.”
   2. “The clinician needs to rule out physical causes for your symptoms.”
   3. “Many mental health disorders can be identified with blood tests.”
   4. “If your lab work is out of balance, then correcting the imbalance will reverse your depression.”

4. The nurse recognizes that the patient who always seems to be making excuses is displaying which ego defense mechanism?
   1. Denial
   2. Fantasy
   3. Rationalization
   4. Transference

5. Which of the following milieus would be most therapeutic for a patient experiencing severe anxiety?
   1. An environment that provides for all the patient’s physical and emotional needs
   2. An environment that is locked and supervised at all times
   3. An environment that is structured to reduce stress and encourage coping behaviors
   4. An environment that eliminates all anxiety-producing stimuli

6. Which explanation of psychopharmacology by the nurse is best for the patient starting on medication for a mental health disorder?
   1. “Medication can potentially cure a mental illness.”
   2. “Medication will help you control your behavior.”
   3. “Medication is used to block emotional responses in your brain.”
   4. “Medication can reduce your symptoms so you can focus on other therapies.”

7. Which statement by the patient with a substance abuse disorder indicates that interventions have been effective?
   1. “I know I have a problem, and I have a lot of work to do to get better.”
   2. “If I don’t think about my problem, eventually it will fade from my memory.”
   3. “I no longer have a substance abuse problem. My treatment has been effective.”
   4. “Now that I know that my family is the cause of my problem, I can move on.”

8. A patient shares some very traumatic life experiences with the LPN. What is the best response by the LPN?
   1. Assure the patient that the staff will not allow such experiences to happen to the patient again.
   2. Ask probing questions about the patient’s emotional responses to the experiences.
   3. Encourage the patient to forget the experiences and move on with life.
   4. Listen attentively to the patient and show empathy.

Answers can be found in Appendix C.

Nursing Care of Patients With Mental Health Disorders

MARINA MARTINEZ-KRATZ

LEARNING OUTCOMES

1. Identify etiological theories for common mental health disorders.
2. Describe signs and symptoms of common mental health disorders.
3. Describe therapeutic management for each of the disorders.
4. Identify actions, side effects, and nursing considerations for selected classifications of psychoactive medications.
5. Plan nursing interventions for patients with mental health disorders.
6. Discuss the role of the LPN/LVN in the care of patients with mental health disorders.

- tolerance (TALL-ler-ense)
- withdrawal (with-DRAW-ul)
As we saw in the last chapter, people with mental health problems may experience impaired ability to think, feel, make sound judgments, adapt to changes, cope with stressors, and form strong relationships with others. This chapter covers some of the more common mental health disorders you will see in medical, surgical, and long-term care settings. Patients with mental health disorders may need modified care planning to help them manage both mental and physiological illnesses.

### ANXIETY DISORDERS, OBSESSIVE-COMPULSIVE AND RELATED DISORDERS, AND TRAUMA- AND STRESSOR-RELATED DISORDERS

#### Anxiety Disorders

Do you ever feel stressed? How does it make you feel? Is it possible to live a completely stress-free existence? Stress is everywhere in our society. Stress produces anxiety. Most often, stress is associated with negative situations, but the good things that happen to us, such as weddings and job promotions, also produce stress. The stress from positive experiences is called **eustress**. Eustress can produce just as much anxiety as negative stressors. A stressor is any person or situation that produces an anxiety response. Stress and stressors are different for each person; therefore, it is important to ask patients what their personal stress producers are.

**Anxiety** is the uncomfortable feeling of dread that occurs in response to extreme or prolonged periods of stress. It is commonly ranked as mild, moderate, severe, or panic. It is believed that a mild amount of anxiety is a normal part of being human and that mild anxiety is necessary to change and develop new ways of coping with stress.

Anxiety may also be influenced by one’s culture. It may be acceptable for some people to acknowledge and discuss stress, but others may believe that discussing personal problems with others is inappropriate. This cultural behavior can be a challenge for the nurse when attempting to collect assessment data.

Anxiety is usually referred to as either **free-floating anxiety** or **signal anxiety**. Free-floating anxiety is described as a general feeling of impending doom. The person cannot pinpoint the cause but might say something like “I just know something bad is going to happen if I go on vacation.” Signal anxiety, on the other hand, is an uncomfortable response to a known stressor (“Finals are only a week away, and I’ve got that nausea again.”) Both types of anxiety are involved in the various anxiety disorders.

#### Etiological Theories

**Psychoanalytical theorists** believe that anxiety is a conflict between the id (the “all for me” part of the personality) and the superego (the conscience), which is repressed in early development but emerges again in adulthood.

**Biological theorists** view anxiety differently. One biological theory points to the sympathoadrenal (fight-or-flight) responses to stress to explain signs and symptoms of anxiety and observes that the blood vessels constrict because epinephrine and norepinephrine have been released, causing blood pressure to rise. Another biological theory implicates a lack of the neurotransmitter gamma-aminobutyric acid (GABA) in the etiology of anxiety. GABA is an inhibitory neurotransmitter that prevents postsynaptic excitation.

If the body adapts to the stress, hormone levels adjust, and body functions return to a homeostatic state. If the body does not adapt to the stress, the immune system is challenged and risk for physical illness increases.

You may observe psychological responses to physical illness. It is important to recognize the relationship between physical and emotional responses to stress. Some examples of medical conditions that occur because of the body’s response to stress are shown in Table 57.1.

### TABLE 57.1 RESPONSES TO STRESS

### WORD BUILDING

**eustress:** eu—normal or good + stress
Diagnosis

Because there are so many symptoms associated with anxiety disorders, it is important for people to have a complete physical examination before diagnosing an anxiety disorder. Some medical disorders, such as hyperthyroidism, can mimic anxiety; hypothyroidism can mimic depression.

Types of Anxiety

SPECIFIC PHOBIA. Specific phobias are the most common of the anxiety disorders. There are more than 700 documented phobias. Specific phobias are defined as irrational fears of distinct objects or situations such as snakes, bridges, or flying. The person is very aware of the fear and even the fact that it is irrational but is unable to gain control over the stressor and the fear continues.

The psychoanalytic view implies that it really is not the object that is the source of the fear but rather that the fear is a result of a defense mechanism called displacement. For example, the person with a phobia of snakes may have seen a frightening movie in which someone died from a snakebite. The stated object of the phobia would be interpreted as a symbol for the underlying cause of the fear, such as fear of dying.

SOCIAL ANXIETY DISORDER (SOCIAL PHOBIA). Social anxiety disorder is a social phobia characterized by a persistent fear of behaving or performing in a way that will be humiliating or embarrassing to the individual, such as public speaking, eating in front of others, or using public restrooms. The fear or anxiety is out of proportion to the situation.

PANIC DISORDER. Panic is a state of extreme fear that cannot be controlled; it may be referred to as a panic attack. Panic episodes are recurrent and occur unpredictably. Patients may present themselves at the emergency room because they believe they are having a heart attack or other significant physical illness. Patients must exhibit several episodes within a specified time frame to be given the diagnosis of panic disorder. Some of the symptoms associated with panic disorder include the following:

- Fear (usually of dying, losing control of self, or “going crazy”)
- Feelings of impending doom
- Dissociation (feeling that it is happening to someone else or not happening at all)
- Nausea
- Diaphoresis
- Chest pain
- Palpitations
- Shaking.

GENERALIZED ANXIETY DISORDER. In generalized anxiety disorder (GAD), the anxiety itself (also referred to as excessive worry or severe stress) is the expressed symptom. Patients with GAD worry about everything. Symptoms that may be present in GAD include the following:

- Restlessness or feeling “on edge”
- Shaking
- Palpitations
- Dry mouth
- Nausea, vomiting
- Easy frightening
- Hot flashes
- Chills
- Muscle aches
- Hypervigilance (excessive attention to stimuli)
Nursing care of patients with anxiety is discussed after “Trauma- and Stressor-Related Disorders.”

**Obsessive-Compulsive and Related Disorders**

The *Diagnostic and Statistical Manual of Mental Disorders* (5th ed., *DSM-5*) (American Psychiatric Association, 2013) groups obsessive-compulsive and related disorders together in a distinct category separate from the anxiety disorders. Disorders grouped in this new category have common features such as an obsessive preoccupation and repetitive behaviors. The disorders included in this new grouping include obsessive-compulsive disorder, body dysmorphic disorder and trichotillomania (hair-pulling disorder), as well as two new disorders: hoarding disorder and excoriating (skin-picking) disorder.

**Obsessive-Compulsive Disorder**

Obsessive-compulsive disorder (OCD) occurs in 2% to 5% of the population and is the fourth most common psychiatric diagnosis. It consists of two parts: the obsession (repetitive thought, urge, or images) and the compulsion (an excessive or unrealistic repetitive act that the individual feels driven to perform in response to the obsession). An example of OCD is the need to check that the doors are locked numerous times before one is able to sleep or leave the house. This need to repetitively check the locks may prevent the person from sleeping or leaving the house at all. Some individuals wash their hands compulsively to the point of having raw and bleeding hands. Behaviors become ritualistic. The person with OCD is unable to stop the thought or the action. Performing the action (such as checking the locks or hand washing) is the mechanism that reduces the anxiety. Although as the nurse you should not interfere with these repetitive acts, OCD patients can be helped by therapeutic interventions such as cognitive-behavioral therapy or medications (such as fluoxetine). Nursing care of patients with OCD is discussed after “Trauma- and Stressor-Related Disorders.”

**Trauma- and Stressor-Related Disorders**

The *DSM-5* (American Psychiatric Association, 2013) created a category to group trauma and stressor-related disorders. Patients diagnosed with these disorders have experienced exposure to a traumatic or stressful event such as war or natural disasters and experience specific symptoms. The disorders included in this new category include posttraumatic stress disorder as well as reactive attachment disorder, disinhibited social engagement disorder, acute stress disorder, and adjustment disorders.

**Posttraumatic Stress Disorder**

Posttraumatic stress disorder (PTSD) develops in response to some unexpected emotional or physical trauma when there was the real threat of death or harm and the patient was helpless to do anything about it. People who have fought in wars, been raped, or survived violent storms or acts (such as terrorist acts) are examples of those who are susceptible to suffering from this disorder.

A condition that is associated with PTSD is *survivor guilt*, which is the feeling of guilt expressed by those who have survived a tragedy. A survivor of an airplane crash may say, “Why me? Why did I make it? I should have died too!” This is especially true if a loved one died in the crash.

Symptoms may appear immediately or may not appear until years later. A key symptom of PTSD is *flashbacks* in which the person may relive the traumatic event as if it were happening at that moment. Sounds and smells associated with the trauma may trigger the flashback.

Signs and symptoms of PTSD include the following:

- Flashbacks or dissociative reactions
- Recurrent intrusive memories of the traumatic event
- Recurrent intrusive dreams/nightsmares related to the traumatic event
- Intense psychological distress at exposure to internal or external cues that resemble an aspect of the traumatic event
- Marked physical reaction to internal or external cues that resemble an aspect of the traumatic event
- Persistent avoidance of stimuli associated with the traumatic events
- Social withdrawal
- Feelings of low self-esteem
- Changes in relationships with significant others
- Difficulty forming new relationships
- Hypervigilance
- Irritability and outbursts of anger seemingly for no obvious reason
- Depression
- Chemical dependency.

**Therapeutic Measures for Patients With Anxiety, Obsessive-Compulsive, or Trauma-Related Disorders**

Treatment for these disorders is individualized and may include one or more of the following: medications (psychopharmacology), individual psychotherapy, group therapy, systematic desensitization, hypnosis, imagery, relaxation exercises, and biofeedback.

Psychopharmacology may involve benzodiazepines, anxiolytics classification of medications. Alprazolam (Xanax) or lorazepam (Ativan) are commonly used and are effective in most cases. Benzodiazepines are used for short-term treatment because of the strong potential for chemical dependency. Individuals who need longer term therapy for anxiety or who have chemical dependency tendencies may be treated with buspirone (BuSpar), the selective serotonin reuptake inhibitors (SSRIs) paroxetine (Paxil) or sertraline (Zoloft), the antihistamine hydroxyzine hydrochloride (Atarax), or the antihypertensive agent clonidine (Catapres). See Table 57.2 for a review of medications.

In *systematic desensitization*, the patient is exposed gradually (rating the fear on a scale from 1 to 10) to the object that causes the anxiety. Hypnosis places the patient in a subconscious state and then helps the patient recall

events that may be producing anxiety so they can be dealt with. Additional therapies are discussed in Chapter 56.

**Nursing Process for the Patient With Anxiety, Obsessive-Compulsive, or Trauma-Related Disorders**

**DATA COLLECTION.** Observe the patient’s anxiety level and level of functioning. Ask about triggers of anxiety and coping mechanisms that have been successful or unsuccessful in the past. Stay alert for physical symptoms, such as changes in vital signs, diaphoresis, or tremor. Assess for the presence of suicidal thoughts and observe for suicidal behavior. It is important to identify anxiety and intervene at lower levels, before escalation to severe and panic anxiety levels.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.**

**Anxiety related to response to stressors**

**EXPECTED OUTCOME:** The patient will verbalize that anxiety is controlled. The patient will identify precipitants and patterns for anxiety and demonstrate techniques to control anxiety. Physical signs of anxiety, such as tremors or changes in vital signs, will be absent.

- Assist the patient to identify precipitants and patterns for anxiety. Recognition of patterns can help guide care and allow the patient to initiate measures to stop anxiety from progressing.
- Maintain a calm milieu and manner. A chaotic environment can increase the patient’s anxiety. Anxiety is contagious and may be transmitted from staff to patient.
- Maintain open communication. Encourage the patient to verbalize thoughts and feelings. Observe nonverbal communication. Honesty in dealing with patients helps them learn to trust others and enhances their self-esteem.
- Encourage the patient to use positive self-talk, such as “I can do this. Anxiety can’t kill me.” This helps the patient replace negative anxious thoughts with positive statements to reduce anxiety.
- Report and document any changes in behavior, such as positive or negative alterations in the way a patient responds to the nursing staff, to the treatment plan, or to other people and situations. Any change can be significant to the patient’s care.
- Encourage activities but avoid placing the patient in a competitive situation. Activities that are enjoyable and nonstressful provide diversion and give staff members an opportunity to provide positive feedback about the progress the patient is making. Competitive situations can produce anxiety.
- Encourage problem solving and assist to develop alternative solutions. Help the patient to identify what has worked in the past. This can help the patient focus on strategies that were effective in the past and eliminate those that are not effective.
- Stay with a patient during acute severe or panic levels of anxiety. Feelings of being abandoned can increase anxiety. The nurse’s presence provides a feeling of safety for the patient.
- Implement suicide precautions if indicated. The patient may need to be protected from self-harm until treatment is effective.
- Assess your own level of anxiety. An anxious nurse may make the patient more anxious.

MOOD DISORDERS

Mood disorders (also called affective disorders) are disorders in which the major symptom is extreme changes in mood (emotions) and affect (the outward expression of the mood). Moods involving both highs and lows are bipolar disorders; low moods without any highs are described as depressive disorders. Mood disorders are diagnosed when symptoms begin to interfere with normal day-to-day functioning. People of all age groups and all ethnic and socioeconomic groups can develop mood disorders.

Etiological Theories

Psychoanalytic theory explains that people who have suffered loss in their lives are at risk for developing depression. Depression is also associated with unresolved anger and has been described as “anger turned inward.” In other words, people who cannot or do not deal appropriately with situations that anger them may repress the anger (turn it inside) and become depressed.

Cognitive theorists believe that the way people perceive events and situations may lead to depression. Instead of thinking about failing an examination as being unfortunate and disappointing, some people with tendencies toward depression may

TOOMMY

EVALUATION. Is the patient able to implement strategies to control anxiety? Does the patient recognize triggers of anxiety? Does the patient state he or she feels less anxious? Are physical signs, such as tremors or changes in vital signs, improved (see Table 57.3)?

1. How can you respond therapeutically?
2. What team member would you use as a resource?

Suggested answers are at the end of the chapter.

MOOD DISORDERS

Mood disorders (also called affective disorders) are disorders in which the major symptom is extreme changes in mood (emotions) and affect (the outward expression of the mood). Moods involving both highs and lows are bipolar disorders; low moods without any highs are described as depressive disorders. Mood disorders are diagnosed when symptoms begin to interfere with normal day-to-day functioning. People of all age groups and all ethnic and socioeconomic groups can develop mood disorders.

Etiological Theories

Psychoanalytic theory explains that people who have suffered loss in their lives are at risk for developing depression. Depression is also associated with unresolved anger and has been described as “anger turned inward.” In other words, people who cannot or do not deal appropriately with situations that anger them may repress the anger (turn it inside) and become depressed.

Cognitive theorists believe that the way people perceive events and situations may lead to depression. Instead of thinking about failing an examination as being unfortunate and disappointing, some people with tendencies toward depression may
exaggerate the emotion and turn the situation into something much deeper, such as thoughts of “I’m stupid” or “I’ll never get anywhere.”

Biological theories offer genetic links and neurotransmitter dysfunctions as two etiologies. Serotonin, norepinephrine, and dopamine have an effect on mood; if these neurotransmitters are elevated, mood is elevated; if they are low, mood is low. Some biological theorists also believe that there is a connection between these neurotransmitters and female hormones.

**Differential Diagnosis**

Symptoms of depression may occur in conjunction with other disorders, such as schizophrenia or drug side effects or overuse. Heart failure, nutritional deficiencies, drug toxicity, thyroid disease, fluid and electrolyte imbalances, infections, and diabetes can be associated with depression.

**Types of Mood Disorders**

**Major (Unipolar) Depression**

Major depression is an episodic condition, and symptoms interfere with the person’s usual social or occupational functioning. Depressed people view the world through “gray-tinted glasses.” The DSM-5 (American Psychiatric Association, 2013) specifies that symptoms of major depression include either a depressed mood or anhedonia (the loss of pleasure in things that are usually pleasurable) along with at least five of the following symptoms:

- Significant weight loss or gain—more than 5% in a month
- Increase or decrease in appetite
- Sleep pattern disturbances—insomnia or hypersomnia
- Increased fatigue or loss of energy
- Increased agitation or psychomotor retardation
- Decreased ability to think, remember, or concentrate
- Feelings of guilt or hopelessness
- Indecisiveness
- Suicidal ideation.

**Bipolar Disorder**

About 2 million people in the United States have bipolar disorder. Formerly called manic depressive illness, bipolar disorder is a mood disorder in which patients experience the mood states of both mania (extreme elation or agitation) and extreme depression. Bipolar disorder is more severe than major depression. Affected people stay depressed longer, relapse more often, display more depressive symptoms, have more delusions and hallucinations, commit suicide more often, require more hospitalizations, and overall experience more incapacitation.

Affected people can cycle slowly (over weeks, months, or even years), or they can be “rapid cyclers” who can change moods several times in an hour. Recent research indicates that individualswith bipolar disorder do not experience periods of normal mood alternating with periods of abnormal mood as previously believed. Instead, bipolar illness is characterized by frequent mood lability, with both manic and depressive symptoms, that are sometimes milder and sometimes more severe (Beddes, 2013).

Common signs of depression were covered in the preceding section. Common signs of mania include the following:

- Excessive high (euphoric) moods lasting at least 1 week
- Increased energy, activity, restlessness
- Decreased need for sleep
- Grandiosity (unrealistic belief in one’s abilities or powers)
- Extreme irritability and distractibility
- Uncharacteristically poor judgment
- Pressured and rapid speech
- Flight of ideas or subjective experience that one’s thoughts are racing
- Increase in goal-directed behavior
- Excessive involvement in pleasurable activities that have a high potential for unpleasant consequences, such as sex, substance abuse, or shopping sprees
- Obnoxious, provocative, or intrusive behavior.

**Therapeutic Measures for Patients With Mood Disorders**

About 80% of people with major depression respond to treatment. Bipolar disorder is more difficult to treat. Some common medical treatments for all mood disorders include the following:

- Antidepressant medications
- Mood stabilizers
- Psychotherapy
- Electroconvulsive therapy (ECT).

Lithium was once the drug of choice for treating bipolar disorder. Lithium is an antimanic medication with a very narrow therapeutic range, which means that toxic drug levels can easily develop. Blood must be drawn regularly to assess that serum lithium levels are in the therapeutic range.

Mood stabilizers such as the anticonvulsants valproic acid (Depakote) and lamotrigine (Lamictal) are now more commonly used than lithium to treat bipolar disorder. Atypical antipsychotics are also commonly used with a mood stabilizer when the patient is in an acute manic state. Antidepressant agents, if used, should be monitored carefully because they can induce a manic episode. See Table 57.2 for a summary of medications. Also see “Nutrition Notes.”

**Nursing Process for the Patient With a Mood Disorder**

See the “Nursing Care Plan for the Patient With Depression.” Also see Table 57.4.

- **WORD • BUILDING •**
  - **anhedonia:** an—not + hedonia—pleasure
BE SAFE!

BE VIGILANT! When collecting data from your patient, be sure to ask about herbal supplements and over-the-counter (OTC) medications the patient may use in addition to prescription medications. Many people take St. John’s wort, an OTC herbal supplement, for depression. Although it may be effective for some people with mild depression, it can interact with many prescribed medications that influence serotonin levels. If combined with prescription serotonin-type antidepressants, it can cause serotonin syndrome, an excess of serotonin resulting in agitation, confusion, diarrhea, muscle spasms, and even death (Lamoure & Stovel, 2011).

CRITICAL THINKING

Mr. Zenz

Mr. Zenz is the manager of a busy office. His usual behavior is rather sullen, and he comes across as quiet or sad to various members of the staff. He is in his 40s and married, with three children, ages 4, 5, and 7. He speaks of them proudly but always comments that they “take after their mother.” His management style in the office is to let people do their jobs; he rarely interferes, although his door is always open and staff members are told they are welcome any time. Recently, however, staff members have noticed a change in Mr. Zenz. He moves quickly, speaks quickly, and has set unrealistic goals for the staff. He frequently says he has called the president of the company to tell him of his new ideas. He says he has not slept in several days and he feels terrific. He has changed his wardrobe and has begun pointing out specific performance issues to staff. He jokes with staff. Staff members are made aware that he has bipolar disorder and has quit taking his medications. His wife has asked for the staff’s help. Remember: He is your boss.

1. How do you respond to Mrs. Zenz?
2. How do you approach Mr. Zenz?

Suggested answers are at the end of the chapter.

TABLE 57.4 DEPRESSION SUMMARY

| Signs and Symptoms | Unipolar: depressed mood, weight changes, anhedonia, sleep disturbance, social withdrawal
| Bipolar: signs and symptoms of depression cycling with euphoria; delusions, hallucinations |
| Diagnosis | History; physiological causes must be ruled out
| Therapeutic Measures | Antidepressant medication, mood stabilizers (anticonvulsants), psychotherapy, electroconvulsive therapy
| Nursing Diagnoses | Risk for Suicide
| Ineffective Coping
| Powerlessness |
# NURSING CARE PLAN for the Patient With Depression

**Nursing Diagnosis:** Ineffective Coping

**Expected Outcomes:** The patient will cope effectively as evidenced by verbalizing the ability to cope and asking for help when needed and by demonstrating new effective coping strategies.

**Evaluation of Outcomes:** Does the patient exhibit increased ability to problem solve and cope with stressors?

**Intervention** Use therapeutic communication techniques to allow the patient to verbalize feelings.

**Rationale** Verbalization of feelings in a supportive environment can assist patient to work through issues.

**Evaluation** Does the patient verbalize feelings to nursing staff?

**Intervention** Assist the patient to describe stressors and identify his or her existing coping skills and knowledge.

**Rationale** Providing validation of actual stress and available coping resources and strategies aids in positive adaptation to stress.

**Evaluation** Is the patient able to identify stressors? Does the patient have some effective coping skills on which to draw?

**Intervention** Help the patient set realistic goals.

**Rationale** Achievement of small steps toward a goal can help the patient feel empowered.

**Evaluation** Does the patient set realistic goals?

**Intervention** Encourage the patient to make choices and participate in care.

**Rationale** Active involvement in care increases the possibility of positive adjustment.

**Evaluation** Is the patient actively involved in care?

**Nursing Diagnosis:** Powerlessness

**Expected Outcomes:** The patient will have reduced feelings of powerlessness as evidenced by verbal expression of having control over life, situation, or care and by participation in care or decision making when opportunities are provided.

**Evaluation of Outcomes:** Does patient identify feelings of powerlessness? Does patient identify factors that are controllable and actively participate in care?

**Intervention** Assess for factors contributing to powerlessness.

**Rationale** Correct identification of actual or perceived problems is essential to providing appropriate support.

**Evaluation** Is the patient able to identify factors contributing to powerlessness?

**Intervention** Help the patient to identify factors that are or are not under his or her control.

**Rationale** Identifying factors within the patient’s control encourages the patient to take some control over the situation.

**Evaluation** Is the patient able to identify what is controllable and what is not controllable in his or her life?

**Intervention** Allow ventilation of powerless feelings.

**Rationale** Sharing feelings in groups can lead to the realization that similar feelings are experienced by others and reduce feelings of powerlessness.

**Evaluation** Is the patient sharing feelings with nursing staff and in therapeutic groups?

**Intervention** Encourage the patient to actively participate in care with goal-directed activities.

**Rationale** Goal-directed behavior increases self-efficacy and empowerment.

**Evaluation** Does the patient set realistic goals daily and achieve them daily?

**Nursing Diagnosis:** Risk for Suicide

**Expected Outcome:** The patient will not harm himself or herself.

**Evaluation of Outcome:** Did the patient remain free from self-harm during hospitalization? Does patient have ongoing support following discharge?
**NURSING CARE PLAN for the Patient With Depression—cont’d**

**Intervention** Ask patient directly about suicidal ideations each shift. **Rationale** Ongoing assessment of suicidal risk is essential to patient safety. **Evaluation** Is the patient verbalizing warning signs of suicide?

**Intervention** Create a safe environment for the patient. **Rationale** Patient safety is a nursing priority. **Evaluation** Are means of harming self kept from patient?

**Intervention** Initiate suicide precautions according to agency protocol. **Rationale** The patient must be protected until risk is reduced. **Evaluation** Is increased surveillance of patient implemented and communicated to all staff?

**Intervention** Encourage the patient to seek out nursing staff when experiencing suicidal thoughts. **Rationale** Active listening and therapeutic communication by staff provide the patient with empathy and alternatives to acting on suicidal thoughts. **Evaluation** Does the patient seek out nursing staff when experiencing suicidal thoughts?

---

### SCHIZOPHRENIA

Schizophrenia is becoming more widely viewed as a group of illnesses rather than a single condition. The term *schizophrenia* (which means “split mind”) was first used by a Swiss psychiatrist, Eugene Bleuler (1911). Schizophrenia is a serious disorder of thought and association and is characterized by inability to distinguish between what is real and what is not and also by hallucinations, delusions, and limited socialization. People who have schizophrenia may not be able to differentiate between what is “theirs” and what is “everybody else’s” in relation to social functioning. Poor self-esteem may be present. It is difficult for them to focus on one topic for any length of time. Schizophrenia is not the same as dissociative identity disorder (once called multiple personality disorder). Schizophrenia has an insidious onset and often begins during adolescence or young adulthood. It develops over time, and symptoms may go unnoticed for a time before diagnosis. There are four phases of schizophrenia:

1. **Schizoid personality.** Those in this phase are perceived as being indifferent, cold, and aloof. They are often described as loners and don’t seem to enjoy close relationships with others. In an adolescent, these behaviors may be dismissed as normal for age. Not all individuals with schizoid personality go on to develop schizophrenia.

2. **Prodromal phase.** Affected people continue to be socially withdrawn and begin to show behavior that is peculiar or eccentric. Role functioning is impaired, personal hygiene is neglected, and disturbances are evident in communication, ideation, and perception.

3. **Schizophrenia.** This is the third and active phase of the disorder. Psychotic symptoms are prominent and include delusions, hallucinations, and impairment in work, social relations, and self-care.

4. **Residual phase.** Symptoms are similar to the prodromal phase, with flat affect and impairment in role functioning.

---

### Positive and Negative Symptoms

Positive symptoms of schizophrenia can be thought of as those symptoms that reflect an “excess” or distortion of normal functioning. Positive symptoms include hallucinations, delusions, disorganized thinking, and disorganized behavior. **Delusions** are fixed, false beliefs that cannot be changed by logic or factual proof. Typically, patients exhibit delusions of grandeur, persecution, or guilt. **Hallucinations** are false sensory perceptions. They can affect any of the five senses; auditory and visual delusions are most common. For example, a person might see a person no one else sees or hear voices that no one else hears. In contrast, **illusions** are mistaken perceptions of reality. For example, a person may see a glowing sunset and think the horizon is on fire. Both typical and atypical antipsychotic medications work well to manage the positive symptoms of schizophrenia.

Negative symptoms of schizophrenia can be thought of as a loss of normal functioning. Negative symptoms include affective blunting or flattening, **alogia**, **avolition**, apathy, anhedonia, and social isolation. It is thought that these are the most debilitating symptoms of schizophrenia because they keep the individual from living a normal life. These symptoms respond to atypical antipsychotic medications but not the typical antipsychotic agents.

### Pathophysiology and Etiology

The causes of schizophrenia are widely believed to be a combination of neurobiological and environmental factors. Psychological factors as the cause of schizophrenia are no longer considered valid because most researchers and clinicians consider schizophrenia to be a brain disease.

The role of genetics in schizophrenia (neurobiological or nature theory) has been examined in twin studies, family studies, and adoption studies for more than 75 years. Studies of

---

### Word Building

- **alogia**: $a - not + logia - (able to) speak
- **avolition**: $a - not + volition - energy or initiative to do something
identical twins show that if one twin has schizophrenia, the other has about a 50% chance of developing it. In fraternal twins, the percentage drops to about 10%. It is believed that the more genes twins or family members have in common, the greater the probability of the second twin developing schizophrenia. Additional support for the role of genetics is demonstrated by adoption studies. Research indicates that children born to mothers with schizophrenia are more likely to develop the disorder even when raised in adoptive families.

Other studies have examined brain structure and the relationship between neurotransmitters and schizophrenia. Patients with a diagnosis of schizophrenia typically have elevated dopamine levels or a brain that overreacts to the amount of dopamine present. Glutamate is an excitatory neurotransmitter that also appears to be related to schizophrenia. The glutamate theory proposes that there is an undersupply of glutamate of the brain (Patil et al, 2007). The brains of patients with a diagnosis of schizophrenia show a significant loss of gray matter, enlarged ventricles, and diminished prefrontal cortex functioning. Today, schizophrenia is primarily thought of as a series of brain disorders characterized by brain abnormalities and neurotransmitter dysfunction.

Environmental factors that increase risk of schizophrenia include such things as central nervous system damage during childbirth, some infections, and substance abuse.

**Symptoms**

Patients with paranoid symptoms tend to exhibit unusual suspicions and fears. The person may also be hostile and aggressive or have delusions of persecution or grandeur. Those with persecutory delusions may state that they feel tormented or followed by people. Patients often integrate people around them into their delusions. They may feel that nursing staff, relatives, or announcers on the radio or television are trying to harm them. In delusions of grandeur, patients might state that they are God or the president of the United States.

Hallucinations often accompany delusions and can affect any of the five senses. The most common hallucinations are auditory, followed by visual. Patients diagnosed with schizophrenia talk about hearing voices. These voices are frightening and derogatory to the patient and are responsible for many of the actions performed by people with paranoid schizophrenia. Patients experience increased fear, anxiety, and suicidal ideation as a result of the voices. You may see or hear patients arguing with what at first appears to be themselves. Actually the patient is arguing with the voices. Describing the voices is difficult, but imagine that you are in a room with six televisions on different stations at the same time. This example comes close to what some patients have described.

**Therapeutic Measures for the Patient With Schizophrenia**

Medications, social skills training, and individual and family psychotherapy are indicated for patients with schizophrenia. Among the classifications of medications that may be prescribed are the typical and atypical antipsychotics, which block dopamine action in the brain.

Among the classifications of medications that may be prescribed are the typical and atypical antipsychotics, which block dopamine action in the brain. There are different dopamine tracts in the brain, and typical antipsychotics have a greater effect on the motor function tract, resulting in extrapyramidal side effects such as parkinsonism (see medications in Table 57.2). Anticholinergic medications such as benztrpipine (Cogentin) or trihexyphenidyl (Artane) are used to combat the extrapyramidal side effects of the typical antipsychotics by helping return balance between dopamine, acetylcholine, and other neurotransmitters. Newer, atypical antipsychotic medications such as clozapine (Clozaril) and risperidone (Risperdal) have fewer extrapyramidal side effects but have other side effects. They are effective in treating both the positive and negative symptoms of schizophrenia.

Psychotherapy can include individual, group, and family therapy. ECT is used in some severe cases or in cases that are difficult to treat; ECT is not usually used until other methods of therapy have been exhausted. Referral of the patient and family to organizations such as the National Alliance on Mental Illness provides helpful education and support www.nami.org.

**Nursing Process for the Patient With Schizophrenia**

**DATA COLLECTION.** Observe the patient with schizophrenia for positive and negative symptoms, including hallucinations, delusions, and illusions. Observe interactions with others. Monitor the patient for response to medications, including side effects. Determine the person’s ability to function and manage activities of daily living (ADLs).

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.**

1. **Disturbed Sensory Perception related to abnormalities in neurotransmitter function**

   **EXPECTED OUTCOME:** The patient will be able to determine what is real and what is not and be able to manage medications, perform ADLs, and function in a community.

   - Develop trust. Be honest and consistent in all areas of the patient’s treatment plan. Trust is essential to a therapeutic relationship.
   - Allow the patient to verbalize thoughts and feelings when appropriate to the time and place. Verbalizing feelings can help the patient clarify concerns and feel supported.
   - Whenever possible, maintain consistent staff assignments to ensure the best possible continuity of care and to promote the development of a trusting relationship.
   - Never whisper or laugh when the patient cannot hear the whole conversation. Face the patient when having a conversation. Whispering or turning away may be interpreted as rejection; secretive behaviors can reinforce paranoia and suspiciousness.
   - Avoid placing the patient in situations of competition or embarrassment. These situations can be threatening to the patient.
   - Never reinforce hallucinations, delusions, or illusions. Orient to reality as needed. The patient needs to know what is real and what is not.
   - Use distraction to deal with the hallucinations (see Table 57.5). Help to connect the delusions and
Hallucinations to times of increased anxiety. This models strategies for the patient to use during times of anxiety.

- Provide a calm and therapeutic milieu to help reduce anxiety.
- Provide written instructions and information boards to help promote reality and self-responsible behavior.
- Monitor medication use and check the patient’s mouth for unswallowed medication as needed. Patients may have difficulty maintaining a medication schedule or choose to not take medications as prescribed due to paranoia or a lack of insight.
- Keep communication simple. Be brief and clear with all directions. State what is acceptable, giving the rationale and consequences at the same time. State information in positive rather than negative terms: “Eat your food calmly” rather than “Do not throw your food!” Patients are more likely to process and respond to simple, direct communication.
- Use touch cautiously. Perceptions and distortions of reality may cause patients to misconstrue touch.

**EVALUATION.** Is the patient oriented to reality? Is he or she able to manage medications, or is there a plan in place to make sure medications are administered? Is the patient able to manage ADLs and live in a community (see Table 57.6)?

### PERSONALITY DISORDERS

How many times have you heard, “She has such a good personality”? What is it that determines an individual’s

---

**CRITICAL THINKING**

**Anne**

- While preparing to invite Anne, a young woman receiving chemotherapy on your oncology unit, to a movie in the day room, you observe her standing in the corner of her room trembling. You ask her what’s wrong, and she responds that she’s talking to the woman in the wall. Your first instinct is to giggle, but you ask her, “What woman?” She tells you that you helped put her there, and you told me that it is my job to be sure she can’t get out. You report this to the charge nurse, who calls the physician. Tests are run, and it is determined that Anne is not experiencing side effects from the chemotherapy. Further workup delivers the diagnosis of schizophrenia for Anne.

1. What therapeutic responses are appropriate for this situation?
2. What special needs might Anne now experience relating to her chemotherapy, if any?
3. How will you get Anne to the movie or to participate in other care activities?
4. What actions can team members take to promote trust with Anne?

*Suggested answers are at the end of the chapter.*

---

### TABLE 57.5 SUGGESTED INTERVENTIONS FOR PATIENTS WITH SCHIZOPHRENIA WHO ARE HALLUCINATING

<table>
<thead>
<tr>
<th>Suggested Action</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. “Mr. R., I don’t see any snakes. It is time for lunch. I will walk to the dining room with you.”</td>
<td>1. Lets the patient know you heard him, but brings him immediately into the reality of time of day and need to go to the dining room.</td>
</tr>
<tr>
<td>2. “I see a crack in the wall, Mr. R. It is harmless; you are safe. Susan is here to take you down to occupational therapy now.”</td>
<td>2. This is in response to a probable illusion. It lets the patient know that you see something. It validates his fear, but it tells him what you see and then moves him into the here and now.</td>
</tr>
<tr>
<td>3. “I know that your thoughts seem very real to you, Ms. C., but they do not seem logical to me. I would like for you to come to your room and get dressed now, please.”</td>
<td>3. Again, you are validating the patient’s concern without exploring and focusing on the delusion.</td>
</tr>
<tr>
<td>4. “Ms. C, it appears to me that you are listening to someone. Are you hearing voices other than mine?”</td>
<td>4. This is a method of validating your impression of what you see. This is as far as you will go into exploring what she may be hearing.</td>
</tr>
<tr>
<td>5. “Thank you, Ms. C. I want to help you focus away from the other voices. I am real; they are not. Please come with me to the reading room.”</td>
<td>5. Responds to her in the present and reinforces her response to you. Attempts to redirect her thinking.</td>
</tr>
</tbody>
</table>
personality? Personality is composed of enduring patterns or traits that determine how an individual perceives, relates to, and thinks about the environment and self. An individual’s personality develops as the person adjusts to their physical, emotional, social, and spiritual environments. Personality traits or patterns are reflected in how individuals cope with feelings and impulses, see themselves and others, respond to their surroundings, and find meaning in relationships.

**Etiology**

The causes of personality disorders are unknown. Genetic and family environmental factors are thought to play a role as well as neurobiological and other social factors.

**Diagnosis**

Personality disorders are diagnosed when the personality patterns or traits are inflexible, enduring, pervasive, maladaptive, and cause significant functional impairment or subjective distress. In the United States, 9.1% of the population has been diagnosed with a personality disorder (National Institute of Mental Health, 2010).

Personality disorders are characterized by the following:

- **Behavioral Manifestations**: Dysfunctional patterns of day-to-day behavior and impulse control
- **Affective Manifestations**: Inappropriate range, intensity, mood lability, and emotional response

**Etiology**

The causes of personality disorders are unknown. Genetic and family environmental factors are thought to play a role as well as neurobiological and other social factors.

- **Affective Manifestations**: Inappropriate range, intensity, mood lability, and emotional response

**Etiology**

The causes of personality disorders are unknown. Genetic and family environmental factors are thought to play a role as well as neurobiological and other social factors.

**Diagnosis**

Personality disorders are diagnosed when the personality patterns or traits are inflexible, enduring, pervasive, maladaptive, and cause significant functional impairment or subjective distress. In the United States, 9.1% of the population has been diagnosed with a personality disorder (National Institute of Mental Health, 2010).

Personality disorders are characterized by the following:

- **Behavioral Manifestations**: Dysfunctional patterns of day-to-day behavior and impulse control
- **Affective Manifestations**: Inappropriate range, intensity, mood lability, and emotional response

**Reasons for Discharge**

Patients with personality disorders exhibit common problem behaviors that create difficulty in daily living. **Manipulation** is a control behavior that uses and exploits others for personal gain. **Narcissism** is self-centered behavior in which the individual feels entitled to special favors or feels justified in not obeying authority and rules. **Impulsive behavior** creates difficulties for those patients who act without considering the consequences of their own behavior.

The DSM-5 lists 10 personality disorders that are organized into three diagnostic clusters, Cluster A: Odd and Eccentric, Cluster B: Dramatic and Erratic, and Cluster C: Anxious and Fearful. This text covers two of the more common personality disorders in Cluster B: borderline personality disorder (BPD) and antisocial personality disorder (ASPD).

**Borderline Personality Disorder**

Individuals with BPD display a pattern of instability of interpersonal relationships, self-image, and affect. There is marked impulsivity. The personality pattern is present by early adulthood and occurs across a variety of situations and contexts. Other symptoms may include intense fear of abandonment, anger and irritability, chronic feelings of emptiness, and transient paranoia or dissociative symptoms. Patients with BPD often engage in idealization and devaluation of others, alternating between high positive regard and great disappointment. This is a defense mechanism referred to as splitting. Self-mutilation and recurrent suicidal behavior, gestures, and threats are common.

**Antisocial Personality Disorder**

ASPD is characterized by a pervasive pattern of disregard for and violation of the rights of others that begins in childhood or early adolescence and continues into adulthood. These individuals have a lack of empathy and/or remorse for their actions. There is a failure to conform to social norms, which often leads to a history of legal problems or criminal behavior. Behavior can be impulsive and aggressive, with a reckless disregard for the safety of self or others. Deceitfulness and consistent irresponsibility is common.

**Therapeutic Measures for Patients with Personality Disorders**

**Psychotherapy**

Psychotherapy is the primary way to treat personality disorders. Using the insight and knowledge gained in psychotherapy, patients can learn healthy ways to manage their illness. Types of psychotherapy used to treat personality disorders include cognitive behavioral therapy and psychoeducation. Cognitive behavioral therapy helps patients identify unhealthy, negative beliefs and behaviors and replace them with healthy, positive
ones. Dialectical behavior therapy is a type of cognitive-behavioral therapy that teaches behavioral skills to help patients tolerate stress, regulate their emotions and improve their relationships with others. Psychodynamic psychotherapy focuses on increasing the patient’s awareness of unconscious thoughts and behaviors, developing new insights and motivations, and resolving conflicts.

Psychoeducation teaches the patient and significant others about their illness, including treatments, coping strategies, and problem-solving skills.

There are no medications specifically approved to treat personality disorders. However, several types of psychiatric medications may help with various common symptoms. Antidepressant medications are used to treat depressed mood, anger impulsiveness, irritability, or hopelessness. Mood-stabilizing medications are used to help even out mood swings or reduce irritability, impulsivity, and aggression. Antianxiety medications can address anxiety, agitation, or insomnia. Antipsychotic medications can help with paranoia, aggression, anger, and impulsiveness.

**Nursing Process for the Patient With Personality Disorders**

**DATA COLLECTION.** A priority nursing action is assessment of suicidal or homicidal ideation. Mood and affect should also be assessed as a depressed, angry, or labile mood can indicate a higher risk for self-injury. Assess for paranoia, manipulative behaviors, and impulsiveness. Assess for history of violence. It will also be necessary to obtain a medical history, psychiatric history, developmental history, and information about sociocultural background.

**NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION.**

Risk for Other-Directed Violence related to impulsivity, impaired judgment and disregard for the rights of others

**EXPECTED OUTCOME:** Patient will not harm self or others. Patient will discuss feelings with staff instead of acting on them. Patient will verbalize adaptive coping strategies for use when hostile or suicidal feelings occur.

• Monitor client’s behavior frequently. Close monitoring is required so that intervention can occur if required to ensure safety.
• Remove all dangerous objects from client’s environment (e.g., sharp items, belts, ties, straps, breakable items, smoking materials). Safety is a nursing priority.
• Redirect violent behavior by means of physical outlets for client’s anxiety (e.g., exercise machines, walking). Physical activity can be an effective way of relieving tension and stress.
• Maintain and convey a calm attitude toward client. Anxiety is contagious and can be transmitted from staff members to client.
• Encourage appropriate verbal expression of emotions. Verbalization of feelings in a nonthreatening environment may assist the patient to develop insight into the situation.

**EVALUATION.** Has the patient been able to discuss anger with staff? Has the patient engaged in physical activity to cope with tension? Is the patient responsive to calm interactions? Are the patient and others safe from harm? Has environmental safety been maintained?

### AUTISM SPECTRUM DISORDER

Autism spectrum disorders (ASDs) are lifelong neurodevelopmental disabilities that are typically recognized during the second year of life. ASD prevalence is believed to occur in about 1% of the population in the United States. ASDs are diagnosed four times more in males than in females.

**Etiology**

Autism spectrum disorders are characterized by abnormal brain development and function. Although the specific causes are unknown, ASD is likely to have multiple etiologies including genetic factors. A range of studies have found in 10% to 37% of cases there may be an associated medical condition such as tuberous sclerosis, fragile X syndrome, maternal rubella, or Angelman’s syndrome. Current research is also showing that the frontal lobe and amygdala appear to have abnormal growth patterns in patients with ASD. A recent study showed that the amygdala, which controls emotions, undergoes disproportionate enlargement by 37 months of age in ASD (Nordahl et al, 2012). Hereditary estimates range from 37% to higher than 90% based on twin studies. Environmental risk factors include advanced parental age, low birth weight, and fetal exposure to valproate, an anticonvulsant medication.

**Signs and Symptoms**

ASD is characterized by:

• deficits in social communication and social interaction and
• restricted repetitive behaviors, interests, and activities (RRBs).

Patients with ASD tend to have communication deficits, such as responding inappropriately in conversations, misreading nonverbal cues, or having difficulty building friendships appropriate to their age. Patients with ASD may desire friendship and interaction with others, but their inability to understand the emotions, motivations, and perspectives of others thwarts efforts toward developing relationships. In addition, ASD patients may be overly dependent on routines, highly sensitive to changes in their environment, or intensely focused on inappropriate items.

**Therapeutic Measures for Patients With ASD**

Early intervention services can greatly improve a child’s development and can help children from birth to 3 years learn important skills. Such services include therapy to help the child talk, walk, and interact with others.

The various types of treatments are targeted toward addressing deficits in communication, social interaction, and behaviors. Applied behavior analysis (ABA) is a notable treatment approach for people with an ASD. ABA has become widely accepted among health care professionals and is used...
in many schools and treatment clinics. ABA encourages positive behaviors and discourages negative behaviors to improve a variety of skills.

Occupational therapy teaches skills that help the ASD patient with activities of daily living such as dressing, eating, bathing, and relating to people. Sensory integration therapy helps the ASD patient cope with sensory information, like sights, sounds, and smells. Sensory integration therapy may help a patient who cannot tolerate certain sounds or physical touch. Speech therapy helps to improve the person’s communication skills either verbally or by using sign language, gestures, or picture boards. The Picture Exchange Communication System uses picture symbols to teach communication skills.

Medications are not a cure for ASD patients and do not address the key symptoms. Some medications can help people with ASD function better by managing high energy levels, inability to focus, depression, or seizures. The U.S. Food and Drug Administration has approved the use of antipsychotic medications risperidone and aripiprazole to treat ASD patients who exhibit behavioral problems such as tantrums, aggression, and self-injurious behaviors. Referral of the patient and family to organizations such as the Autism Education Network www.autismeducation.net or Autism Speaks www.autismspeaks.org/family-services/resource-guide can provide helpful education and support.

**Nursing Process for the Patient With ASD**

**DATA COLLECTION.** Assess the patient for developmental spurts or lags, uneven development, or loss of previously acquired skills. Observe the caregiver–patient relationship for bonding, anxiety, tension, and difficult fit. Discuss the patient’s social, communication, and behavioral strengths and limitations with the care giver. Assess the ASD patient for communication style and verbal and nonverbal skills. Assess for risk of injury to self and others, and be alert for the potential for abuse.

**NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION.**

**Impaired Social Interaction related to neurological alterations**

**EXPECTED OUTCOME:** Patient will interact appropriately with at least one staff member. Patient will develop trusting relationship with at least one staff member. Patient will function appropriately in the inpatient milieu.

- • Assign consistent staff to the patient. This is essential to the development of trust.
- • Provide positive reinforcement for patient’s voluntary interactions with others. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors.
- • Provide direct feedback about patient’s interactions with others in a nonjudgmental manner. Direct feedback from a trusted individual may help to alter behaviors in a positive manner.
- • Help client learn how to respond more appropriately in interactions with others. Practice new skills through role-play. Practicing skills in role-play facilitates their use in real situations.
- • Give positive feedback when eye contact is used. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors.

**EVALUATION.** Has the patient been able to establish trust with at least one staff member? Has the patient engaged in voluntary interaction with others? Is the patient responsive to feedback regarding interactions? Is the patient responsive to role-plays? Does the patient make eye contact?

**SUBSTANCE-RELATED AND ADDICTIVE DISORDERS**

Alcohol and drug use disorders are serious conditions. People start using alcohol and drugs for many reasons, but often it is to feel accepted by a peer group or to feel comfortable and reduce anxiety in a social situation. People mistake the temporary high as a stimulant. In reality, alcohol is a depressant. Any chemical can be potentially dangerous.

It is important to understand the following terms and their definitions:

- • **Addiction**—repeated compulsive use of a substance that continues despite negative consequences (physical, social, legal).
- • **Tolerance**—a condition in which increased amounts of a substance are needed over time to achieve the same effect as that previously obtained with smaller doses.
- • **Physical withdrawal** syndrome—a physiological response to the abrupt stopping or reduction of a substance used (usually) for a long time. Withdrawal symptoms are specific to the substance used.

The substance-related and addictive disorders are conditions in which the patient:

- • Takes more of the substance or over a longer period of time than intended
- • Has a persistent desire to or unsuccessful efforts to cut down or control use
- • Experiences strong craving for the substance
- • Is unable to fulfill major role obligations at home, work, or school
- • Needs more of the substance and at more frequent intervals to achieve the same “high,” or desired effect of the substance (tolerance)
- • Spends significant time obtaining the substance
- • Gives up important social or professional functions to use the substance
- • Has tried at least once to quit but still obsesses about the substance
- • Experiences difficulty with job, family, or social activities because of use or withdrawal symptoms
- • Uses the substance regardless of the problems it causes
- • Experiences the substance-specific withdrawal syndrome
- • Uses the substance to avoid withdrawal symptoms

Nurses need to be informed about chemical dependency for several reasons. First, many patients on medical-surgical units are chemically dependent. This affects their healing and the
effect of their medications. Second, as part of the human experience, your chance of being in a close personal relationship with a person who is chemically dependent is great. Third, and perhaps most important, you are part of a profession whose members are statistically high users and abusers of drugs and alcohol (see “Ethical Considerations” on DavisPlus). According to the National Council of State Boards of Nursing (2011), between 6% and 15% of nurses in the United States are chemically impaired.

Substance abuse is not a one-person illness; it affects personal and professional relationships with people who are associated with the user. The term dysfunctional is often used to refer to the relationships in an alcoholic family or work environment. Dishonesty and inability to discuss the situation are strong components of the disease. Many times, people who live or work in the dysfunctional group begin to cover up for the user’s behaviors and lack of responsibility. Family members or significant others may take sides, begin to be dishonest with each other, and erode the bond within that group. Eventually this leads to a condition called codependence, which can be as serious as the use and abuse of the substance. Codependent members of a family group begin to lose their own sense of identity and purpose and exist solely for the abuser. Their actions take away the opportunity for the user to take responsibility for his or her own actions. This is called enabling.

Etiological Theories

Why do some people become addicted or dependent and others do not? Can it be the chemical, or is it the person? Some theorists believe in the existence of an addictive personality, which may begin to explain addictions to food, sex, and gambling, as well as alcohol, chemicals, and other dependencies.

Psychoanalytical theorists believe that people who develop addictions to alcohol or other substances are people who filled to successfully pass through the “oral” stage of development.

Biological theories include numerous studies that imply some sort of genetic metabolism disorder. Many of these studies were done on twins born to an alcoholic parent or parents and who were separated from the parents at birth or shortly after birth. The number of twins who were born of alcoholic parents but raised by nonalcoholic adoptive or foster parents and yet developed alcoholism was consistently elevated.

Cognitive-behavioral theorists suggest the why in which a person perceives being high may influence the act of becoming high. It can be an innocent be ginning: obtaining relief from valid prescription medications can, according to cognitive theory, leave people perceiving that the drugs are a miracle cure. It becomes appealing to want that kind of relief again, and soon a pattern is formed, and other substances may be added.

Differential Diagnosis

A patient with a chemical dependency may be admitted to the hospital for medical problems associated with the substance use (dehydration, liver failure) or for unrelated problems (cancer, diabetes). Nursing assessment, unexplained tolerance to pain medication, or symptoms of withdrawal may lead you or the physician to pursue the possibility of chemical dependency. Laboratory tests can rule out physiological problems. Drug levels of alcohol or drugs can also be measured. A patient who is uncommonly anxious for early discharge should also be further assessed.

Alcohol Use Disorders

Use and abuse of alcohol is present in all walks of life, at all economic levels, and in both genders. Sometimes a fine line exists between a person who is a social drinker and a person who has an abuse condition. One factor used to make that differentiation is the degree of need or compulsion to drink. There is a high incidence of alcohol use and abuse among older adults, teenagers, and even younger children. Alcoholism either directly or indirectly decreases a person’s life expectancy by an average of 10 to 12 years.

Denial is a common ego defense mechanism used by people who are substance abusers. The person who is alcohol-dependent often uses statements such as “I can quit anytime I want to” or “I just need a little bump to loosen me up.”

Characteristics of substance use disorders were described earlier. In addition, patients with alcohol use disorders may experience:

- Binges usually lasting 2 days or more
- Blackouts (unable to recall what happened during a period of drinking)
- Vomiting and dehydration
- Disorientation
- Increased vulnerability to infections, accidents, and other injuries

Sometimes patients who are actively using drugs or alcohol when admitted to an inpatient setting, or who are cut off from sedatives or alcohol abruptly, experience a condition called delirium tremens (DTs). The DTs develop when alcohol intake is significantly reduced and the neurotransmitters previously suppressed by alcohol are no longer suppressed. They rebound, resulting in a phenomenon known as brain hyperexcitability. Hyperexcitability can cause visual hallucinations, tremors, and possibly tonic-clonic seizures. Elevated blood pressure and pulse and cardiac dysrhythmias also may occur. Symptoms of withdrawal begin within 4 to 12 hours after the patient has stopped drinking and will peak in 24 to 48 hours. Hospitalization is needed to maintain the patient’s safety.

Therapeutic Measures

Treatment for and recovery from alcohol use disorders is a slow process. With few exceptions, a person who has an alcohol dependency and who is recovering cannot ever have another drink, or he or she will risk the chance of returning to previous abusive patterns. Some treatment options are described next. Several forms of treatment may be used together.

SUPPORT GROUPS. A common and effective treatment for alcoholism is involvement in Alcoholics Anonymous (AA). AA

- WORD BUILDING
  - dysfunctional: dys—bad or difficult + functional—performance
is a 12-step program that of fers support through others who have stopped drinking. For more information on AA, go to www.alcoholics-anonymous.org. Another program for women only is called Women for Sobriety www.womenforsobriety.org.

**COGNITIVE-BEHAVIORAL THERAPY.** Cognitive behavioral therapy is used as an adjunct therapy for control of substance abuse. Cognitive behavioral therapy advocates believe that with homework and practice, a person can learn to think differently about the event that led to the drinking. When the person changes the belief system about the acti vating event and the drinking, the consequences of drinking will be less powerful.

**PSYCHOTHERAPY** Psychotherapy provides one-on-one therapy. Because substance use affects an entire family, family therapy is important in reinstating honest communications. A commitment to stop drinking is required, and therapy will only help with some of the issues resulting from years of drinking.

**MEDICATIONS.** In the United States, aversion and anticinging medications have been approved to treat alcohol use disorders. If a comorb red anxiety or depression disorder accompanies the alcohol ab use, other medications may be prescribed. Antidepressant or nonaddictive antianxiety drugs are most often prescribed.

Disulfiram (Antabuse) is an a version medication that is sometimes prescribed as a deterrent to using alcohol. Disulfiram should never be administered without the patient's full informed consent. If a patient taking disulfiram ingests alcohol, a severe reaction causes chest pain, nausea, vomiting, confusion, and other symptoms. Those taking disulfiram also can be adversely affected if they use products that contain alcohol, such as cologne mouthwash, aftershave, or cough syrup. The effects of disulfiram last 2 to 3 weeks after the last dose.

Acamprosate (Campral) is a newer drug that is thought to work by helping to restore GABA-glutamate equilibrium. Campral is used to combat cravings and is specifically indicated for maintenance of abstinence from alcohol in patients who have stopped drinking.

Naltrexone (ReVia) may reduce craving, which is the urge or desire to drink. Naltrexone helps patients remain abstinent and can interfere with the tendency to want to drink more if a reinforcing effect of drinking is present and ingests alcohol.

Use of benzodiazepines such as diazepam (Valium) and lorazepam (Ativan) can help prevent symptoms of DTs during acute withdrawal by neurotransmitter action but are not used long term because of risk for dependence.

**HOSPITALIZATION.** Therapy may range from in-house hospitalizations to halfway houses to eventual independence, usually with attendance at AA meetings. It is common for patients to seek treatment multiple times. This should not be interpreted as a weakness in the patient or the treatment program. It is only a sign that the person is learning more about the disorder and the need to help himself or herself. People with all kinds of chronic diseases experience relapse at times.

### Chapter 57 Nursing Care of Patients With Mental Health Disorders 1375

### Nursing Process for the Patient With Alcohol Use Disorders

**DATA COLLECTION.** A common screening tool to determine if a patient has a drinking problem is the CAQGE questionnaire (Ewing, 1984):

- Have you ever felt you should Cut down on your drinking?
- Have people Annoyed you by criticizing your drinking?
- Have you ever felt bad or Guilty about your drinking?
- Have you ever had a drink first thing in the morning (as an “Eye opener”) to steady your nerves or get rid of a hangover?

A “yes” answer to two or more questions suggests a drinking problem.

Alcohol also can have many physiological effects. See Chapter 32 for assessment of patients with liver disorders.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.**

**Ineffective Coping related to lack of effective coping mechanisms as evidenced by abuse of alcohol**

**EXPECTED OUTCOME:** The patient will accept responsibility for her or his behavior, verbalize acceptance of the relationship between substance abuse and personal problems, and identify effects of alcohol on the body.

- Help patient to identify recent behavior while under the influence of alcohol. Patients need to see the relationship between their substance abuse and their personal problems.
- Expect sobriety. This establishes sobriety as the norm.
- Teach about the physical impact of drugs and alcohol on the body. Many patients lack accurate information about the effects of substance abuse on the body.
- Be honest; be aware of your own thoughts and feelings about addictions. Effective communication is essential for a therapeutic relationship.
- Provide group support such as a 12-step program. Many chemical dependency units provide group support meetings. Peer support is an effective treatment that is often more acceptable to patients than other treatments.
- Confront the patient immediately if projection, rationalization, or denial behaviors are noted. Projection, rationalization, and denial are ego defense mechanisms that discourage the patient from accepting responsibility for behavior.
- Use positive reinforcement. Positive reinforcement for successes is important when helping a person with an addiction. Every step is a big one in this field; every step taken is a new one.
- Provide a safe environment. Patients who are chemically addicted may become suicidal or display other bizarre behavior, especially during withdrawal. A patient under the influence of alcohol or another chemical may have poor impulse control or judgment. Maintaining a safe milieu and calm demeanor will help the patient through this difficult time.
- Remain alert to the possibility that the patient may be using a substance even in the hospital. Express suspicions honestly and nonjudgmentally to the patient. Report and document all findings and behaviors that may be potential
safety hazards for the patient. The fact that a patient is hospitalized does not guarantee that he or she has no access to the chemical or way of using it in your presence. Unfortunately, family members or friends sometimes smuggle drugs or alcohol into patients.

• Practice “tough love.” “Doing for” patients may be tempting, but it is not in the patient’s best interest most of the time. This encourages patients to be responsible for their own healing.

EVALUATION. Does the patient verbalize acceptance of responsibility for own behavior? Does the patient understand the relationship between personal problems and substance abuse? Does the patient understand the effects of substance abuse on the body?

For additional information, visit the National Institute for Alcohol Abuse and Alcoholism at www.niaaa.nih.gov.

Other Substance Use Disorders

Many substances other than alcohol can be addictive. Caffeine and nicotine are two that are readily available. Coffee, tea, soda, and cigarettes are everywhere in our society and are very addicting. Many experts believe that the single most difficult addiction to overcome is to nicotine.

Illegal substances such as marijuana (in some states), cocaine, crack, phencyclidine (more commonly known as PCP), and prescription medications for pain and mental health treatment are also potentially addictive. Methamphetamine (meth) has led to a substantial substance abuse problem affecting families and society. Inhalants such as lighter fluid, paint, paint thinners, and gasoline also can be used to get high; in the United States, these substances are mainly used by teenagers. The term for their use is huffing. These are highly neurotoxic substances, potentially lethal, and usually available in the house or garage.

Signs and Symptoms

The signs and symptoms of drug abuse and dependence can be similar to those of alcohol abuse. Additional signs of drug abuse include the following:

• Red, watery eyes
• Runny nose
• Hostile behavior
• Paranoia
• Needle tracks on arms or legs

Therapeutic Measures

Therapeutic measures for patients with drug abuse and dependence include the following:

• Narcotics Anonymous
• Group therapy
• Psychotherapy
• Methadone programs

Methadone acts as a sort of “step down” for people addicted to certain opioid drugs. Methadone can be legally prescribed and dispensed. It, too, is potentially addicting, and its critics believe it is only a substitute for heroin. It is typically given once a day. Psychotherapy is also provided for patients in methadone programs.

Nursing Care

Nursing care for people who are drug dependent is essentially the same as for those who are alcohol dependent. It is important to remember that nurses and physicians cannot “fix” the patient who is chemically dependent. The desire to be chemically free must come from the person who is addicted (see Table 57.7 for a Substance Abuse Summary).

### Critical Thinking

Maria

You are a school nurse in your local high school. You notice that Maria, a 17-year-old student, is behaving oddly. She has always been rather loud and even has been referred to as “obnoxious” by several of her peers. Lately you have observed her sitting alone, as if waiting for someone, but when you approach her, she barely greets you and then moves away.

1. What are your concerns about Maria?
2. What are some of the possibilities that might be affecting her?
3. How can you approach her more effectively the next time you see her?

Suggested answers are at the end of the chapter.

---
MENTAL ILLNESS AND THE OLDER ADULT

It is not uncommon for older adults to be admitted to the hospital with a tentative diagnosis of “change in mental status.” It is important to distinguish between physical and mental disorders in these circumstances. Some neurocognitive disorders that affect older adults’ mental status are as follows.

- **Major Neurocognitive Disorder** is an impairment of mental functioning that interferes with daily activities and relationships. Causes of major neurocognitive disorder include Alzheimer’s disease, Lewy body disease, vascular disease, Huntington’s disease, HIV infection, and others.
- **Delirium** is an acute change in mental status needing immediate evaluation and treatment. This is often due to a physiological condition such as an infection and can be reversed if recognized and the underlying cause is removed. Read more about dementia and delirium in Chapter 48.
- **Pseudodementia** is a condition in which the patient appears to have a major neurocognitive disorder but is really experiencing depression. Treating the depression can help reverse the mental status changes.
- **Depression** in older adults should not be viewed as a normal part of aging; it should be diagnosed and treated. Older adults may be dealing with physical and mental decline, loss of function, isolation, and loss of a marriage partner and friends; they may express their depression through bodily symptoms such as pain. If not evaluated and treated, depression can lead to suicide (see “Gerontological Issues”). Be sure to review Chapter 15, “Nursing Care of Older Adult Patients.”

Crisis Intervention for a Suicidal Older Adult

- Remove any items that the older adult could use to inflict an injury or end his or her life, such as razors, jewelry with pins or sharp points, and mirrors.
- Make arrangements for direct supervision and observation that are reliable, considering personnel and family resources. Often, hospital admission is the most appropriate intervention for a person at a high risk for suicide.
- Help the older adult talk about the crisis or life event that has devastated his or her desire to live. For example, encourage reminiscence about the patient’s spouse, or allow the older person to express the frustration of being unable to physically meet the daily demands of life.
- Develop a “do no harm” or suicide contract with the older adult. Outline a short-term, structured plan to keep the older adult safe. Focus on decreasing social isolation by requiring personal social contacts (e.g., stay at daughter’s home for a weekend; go to the senior center for lunch; call a specific person who is willing and wants to listen to feelings and concerns; exercise; take a walk outside; volunteer services at a nursing home, hospital, or school).

Older adults often need assistance to develop or enhance skills required to cope with life events. Self-care and personal independence in care choices can be encouraged.

**Gerontological Issues**

**Suicide and the Older Adult**

Older adults are not immune to suicidal thoughts. In North America, white men older than age 75 have an especially high suicide rate. Comments by an older adult referring to hopelessness or desire to die must be explored to assess suicide risk. The following comments could be a reflection of suicide potential in an older adult who is depressed:

- “Living is harder than dying could ever be.”
- “I am a used-up old man who is a burden for everyone.”
- “I am useless. I can’t do anything anymore.”
- “I don’t know why God won’t take me.”

To adequately assess suicide potential, ask questions that establish whether the older adult has done the following:

- Thought about ending his or her life
- Attempted to end his or her life in the past
- Developed a plan to end his or her life
- Has started to give away as “gifts” his/her personal prized objects

**Home Health Hints**

- Help patients and families identify pharmacies that will deliver medications to the home.
- Set up medications using a system the patient can easily follow.
- Maintain communication with and act as a liaison between the psychiatrist and primary care provider as needed.
- Assist the patient and family to identify community resources such as support groups and respite care.
- Assess family members for evidence of caregiver role strain.
- Provide education for family/caregivers related to the patient’s illness, medications, and symptom management.
CRITICAL THINKING

Tommy
You can reassure Tommy’s mother that his OCD is not her fault. Tommy can learn to control his illness with medications and therapy. The family must be part of the therapy, for both Tommy’s and the family’s sake. Positive communication between Tommy and his family is encouraged. Tommy’s mother can also be encouraged to attend a support group herself. Suggest to Tommy’s mother that she meet with a counselor or behavioral therapist to learn more about the causes and treatment of the disorder.

Mr. Zenz
It is important to be supportive of Mrs. Zenz while maintaining her husband’s confidentiality and privacy. Encouraging Mrs. Zenz to talk to Mr. Zenz’s physician is appropriate. Showing empathy with statements such as “It must be confusing and difficult to watch your husband change moods so quickly” are good tools to use. It may be a bit more challenging to approach him as your boss. You may certainly ask him if you can speak frankly and share specific observations. You may share your concern, such as “Mr. Zenz, you are a wonderful boss, but I am frightened when you become loud and boisterous.” This may help him to reflect. Chances are, however, that if he is in a manic stage, he will not hear your concern. It may require a delicate conversation with the next person up in the corporate chain of command, being careful to objectively report behavior but not share assumptions. This is a tough one. Good luck!

Anne
Appropriate communication skills include being positive, reassuring, and not reinforcing the hallucinations. “I don’t see or hear a woman, Anne. It is time for the movie. I’d like you to come with me for a while at least” is an example of an appropriate verbal interaction. Reinforcing expectations is also appropriate; you might say “Anne, part of your care plan includes attending one unit activity each day. This is the last opportunity for you to meet your care plan objective for today.” At all times, nurses need to be aware of drug interactions. Anne will most likely be medicated for her schizophrenia, and those medications can interact unfavorably with her chemotherapy. If she is receiving oral medications, it may be necessary to check her mouth to ensure she is swallowing them. Work with team members to provide a therapeutic and low stimulus environment for Anne. Good nursing data collection skills are essential.

Maria
A number of options may explain Maria’s behavior, including depression, drug use, schizophrenia, or an eating disorder. Next time you see Maria, you might try constructively confronting her behavior by saying something like “Maria, you used to be much more outgoing. We always were friendly, and now you leave when I’m near. That change in you concerns me. I’m here if you want to talk.” Or “Maria, I see your behavior is changing. You are loud one moment and very quiet the next. That is unusual for you. What’s happening?”

REVIEW QUESTIONS

1. Which statement by a depressed patient causes the LPN to contact the RN or HCP immediately?
   1. “Everyone is out to get me.”
   2. “I have tried to kill myself three times.”
   3. “I feel so hopeless.”
   4. “My friend is bringing me a gun.”

2. A patient states, “My doctor says I have obsessive-compulsive disorder. What does that mean?” Which response by the nurse is best?
   1. “It means that you have experienced a major life stress and will need therapy to help you manage the symptoms.”
   2. “You can expect to experience periods of high energy and anxiety, alternating with periods of feeling very low.”
   3. “You may experience involuntary, intrusive thoughts, and feel compelled to respond with seemingly meaningless actions.”
   4. “People with obsessive-compulsive disorder are very organized. This is a good disorder to have.”
Chapter 57  Nursing Care of Patients With Mental Health Disorders

3. A patient is experiencing extrapyramidal side effects while taking antipsychotic medication. Which medication on the patient’s orders will help reduce these effects?
   1. benztropine (Cogentin)
   2. chlorpromazine (Thorazine)
   3. haloperidol (Haldol)
   4. lithium (Eskalith)

4. A patient who is a veteran of the Gulf War hears the hospital fire alarm go off during a drill and cries, “There are people hiding behind the pillars! They have guns! Be careful!” What action should the nurse take first?
   1. Tell the patient that his behavior is inappropriate and that he is frightening the other patients.
   2. Administer an as-needed (prn) antipsychotic medication as ordered.
   3. Ask him if he is afraid of the guns.
   4. Stay with the patient while calmly reorienting him.

5. A patient is being treated on the mental health unit for an anxiety disorder. The patient approaches the nurse and reports feeling dizzy and weak, with a sensation of a racing heart. The nursing care plan includes interventions of imagery exercises and prn lorazepam (Ativan) for symptoms of anxiety. What should the nurse do first?
   1. Instruct the patient to sit and breathe deeply.
   2. Give the patient the prescribed prn lorazepam.
   3. Obtain the patient’s vital signs.
   4. Instruct the patient in an imagery exercise.

6. A patient reports seeing children playing on the floor in the hallway of the mental health unit. There are no children anywhere on the unit. Which response by the nurse is best?
   1. “The children are fine there; they are just playing.”
   2. “I don’t see any children, and there haven’t been any children on the unit today. Would you like to walk with me?”
   3. “Children are not allowed on this unit. I will ask them to leave.”
   4. “You know there are no children here. It must be time for your medication.”

Answers can be found in Appendix C.

Diagnostic Tests

This is intended to be a quick reference only. Please check a diagnostic test reference manual for comprehensive information.

**GENERAL CONSIDERATIONS FOR ALL TESTS:**

- Ensure that an informed consent form is signed before any invasive procedure.
- Check orders for need to withhold food or fluids before test.
- Preparation if contrast media will be used: (1) assess for and report allergies to iodine or contrast media; (2) report elevated creatinine/blood urea nitrogen (BUN) levels because dye is nephrotoxic and excreted by the kidneys; (3) consider patient risk factors for contrast-induced nephropathy and discuss with health care provider (HCP) prophylaxis orders such as holding nephrotoxic medications (nonsteroidal anti-inflammatories, aminoglycoside antibiotics, cisplatin, cyclosporin A, amphotericin B) 24 hours or more before the test, and providing intravenous (IV) hydration; (4) if patient is taking metformin, obtain order to hold it before and 48 hours after test to prevent risk for lactic acidosis; (5) encourage fluids after test to promote excretion of dye; and (6) teach that the patient may experience a feeling of warmth or experience a salty or metallic taste when the dye is injected.
- Reinforce patient education for test.

</tbody>
</table>
### Electroencephalography (EEG)

- **Description:** Electrodes on scalp evaluate electrical activity of the brain.
- **Reasons Done:** To evaluate brain activity, lesions, seizures.
- **Preprocedure Considerations:** Ensure patient’s hair is clean and dry. Check orders for drugs such as sedatives or stimulants that may need to be weaned or withheld before test.
- **Postprocedure Considerations:** Wash adhesive from hair before it hardens and becomes difficult to remove. Oil or witch hazel may make removal easier. Instruct patient about resuming medications as ordered.

### Endoscopy
- **bronchoscopy**
- **colonoscopy**
- **colposcopy**
- **gastroscopy**
- **sigmoidoscopy**

- **Description:** A flexible fiber-optic tube and camera are inserted into a body cavity to observe structures.
- **Reasons Done:** To observe for abnormalities, remove polyps, obtain biopsy specimens, suction secretions, coagulate bleeding sites, and more.
- **Preprocedure Considerations:** Check orders for preparation such as NPO (non per os), laxatives, enemas. Premedicate as ordered.
- **Postprocedure Considerations:** Check for swallow and gag reflexes after upper endoscopy before offering food or fluids.

### Lumbar puncture (spinal tap)

- **Description:** A small needle is used to withdraw cerebrospinal fluid for examination. The needle is typically inserted between the L3–4 or L4–5 vertebrae.
- **Reasons Done:** To diagnose infection, central nervous system disease, or cancers. Sometimes used to inject medication.
- **Preprocedure Considerations:** Premedicate as ordered. Assist patient to sit leaning forward or lay curled up on side according to HCP preference. Be prepared to assist with procedure.
- **Postprocedure Considerations:** Label specimens and take to laboratory. Monitor site. Implement activity restrictions if ordered. Encourage fluids.

### Magnetic resonance imaging (MRI)

- **Description:** Magnetic field and radiofrequency energy are used to obtain a detailed image of tissues. Contrast media may be used.
- **Reasons Done:** To visualize structural abnormalities in organs and tissues.
- **Preprocedure Considerations:** Because powerful magnets are used, question patient about metallic foreign bodies, pacemakers (some new models are MRI compatible), or tattoos with metal-based inks, which are contraindications for this test. Assess for claustrophobia; patient will be in scanner for up to 1 hour. Consider open MRI availability. Request order for sedative or analgesic to be given 1 hour before test if necessary.
- **Postprocedure Considerations:** Encourage hydration if contrast media used.
### Myelography

Contrast media is injected into cerebrospinal space following lumbar puncture. Radiographs are then taken to outline the vertebrae. Identifies spinal column abnormalities. Same as lumbar puncture. Maintenance bedrest with head elevated less than 30 degrees. Monitor for seizures. Encourage hydration to promote excretion of contrast media.

### Nuclear scan

- heart
- lungs
- CNS
- thyroid
- bone
- other

Radioactive substances are administered (orally, inhaled, or IV), then a special scanner observes where the substance is distributed. To show both structure and function abnormalities. Check HCP orders for preparation, which may differ for each scan type. Teach patient that the amount of radioactive material is very small, and no special precautions are needed. Encourage hydration to promote excretion of radioactive material.

### Radiograph (X-ray)

X-ray beams identify internal structures, especially high-density structures such as bone. Contrast media may be used with some tests. To identify differences in tissue densities. Can help diagnose a variety of structural or other disorders. Have patient remove jewelry from area to be x-rayed. Laxatives or enemas may be ordered before some gastrointestinal x-rays. If barium has been used as contrast media to outline the bowel, administer laxative as ordered and increase fluid intake to help evacuate barium before it hardens.

### Ultrasonography

- Endoscopic ultrasound—transesophageal echocardiogram, transrectal ultrasound, transvaginal

High-frequency sound waves are passed through soft tissues to outline tissues and masses. Gel is used on skin and transducer to improve conduction of sound waves. To identify alterations in soft tissues and organs. Check orders for preparation if ultrasound will be done endoscopically. None specific.

Reference range values may differ from one institution to another. BNP = brain natriuretic peptide; hpf = high-power field; SI = International System of Units.

Appendix C

Answers to Review Questions

Chapter 1
1. 2. Critical thinking is use of cognitive skills or strategies that increase the probability of a desirable outcome.
2. 4. Asking a question shows humility. The nurse does not “know it all.”
3. 1. A respiratory rate of 28 is observable. Selections 2, 3, and 4 are patient perceptions.
4. 4. Selections 1, 2, and 3 all include the nurse’s perceptions.
5. 3. Shortness of breath is a physiological need and should be addressed first.
5. 1, 4, 5, 2. These are the steps of the nursing process.
7. 1. The LPN implements interventions and assists the RN with the other steps.
8. 4. Acute Pain is a nursing diagnosis. The others are medical diagnoses.
9. 3. The patient who has a specific plan is most likely to be successful.

Chapter 2
1. 4. Providing an explanation of why something is done promotes the understanding for why it is important to be done and therefore will more likely be done.
2. 4. Evidence-based nursing care provides the best and safest patient care.
4. 3. The proposed change will need to go through the policy and procedure committee for evaluation.
5. 3. Systematic reviews of randomized controlled trials are the best place to look for evidence.
6. 2. A soft toothbrush/fluoride toothpaste is needed to remove plaque from the teeth.

Chapter 3
1. 2. The older adult population is growing and will require more complex health care.
2. 1, 2, 3, 4. Assessment of conditions present on admission and all care and education to prevent complications, including patient refusal to participate, must be documented during hospitalization.
3. 3. All but ambulating a patient are outside the LPN scope of practice.
4. 2. Autocratic leaders do not seek input to make decisions.
5. 1. LPNs consult with RNs in caring for their patients.
6. 4. Acting on fidelity, because the patient is an adult, the nurse does not provide false information but tells the mother to talk to her daughter, who decides how to answer her mother’s questions.
7. 3. When patients refuse treatment, it can be a dilemma related to life and death. However, if patients are given correct information and understand the consequences of actions, it is their choice to refuse treatment. It is never OK to coerce patients with fear or make them feel badly about their decision.
8. 1. If the patient has a valid advance directive and the health care provider (HCP) uses a deontological perspective (i.e., Do what’s right) and supports autonomy (i.e., The patient’s wishes), then a feeding tube will not be inserted. This does not necessarily mean that the advance directive stated do not resuscitate (DNR).
9. 2. Utilitarianism supports decisions based on the best outcome for the greatest number of the people (Butts & Rich, 2013).
10. 2. A patient who is asking to die may be feeling depressed, especially if he or she is missing family. It is a good idea to try to understand more about how the patient is feeling. While getting such patients involved in activities may be helpful, it is not a good idea to minimize their feelings. In addition, although empathizing with feelings can help, option “d” is not therapeutic because the nurse is not in the same situation as the patient. It is never OK to medicate the patient to “numb” these feelings.
11. 1, 3, 5. Institutional policies outline the proper manner for performing certain tasks and procedures for employees who must comply with them; state nurse practice laws outline the scope of practice in a given state that nurses must abide by when practicing under license in that state; local nursing standards of care identify the degree of prudence and caution required for proper nursing practice.
12. 1, 4, 5. See Box 3-3.
13. 2. The Health Insurance Portability and Accountability Act (HIPAA) requires protection for the privacy of personal health information.

Chapter 4
1. 2. Ethnocentrism is thinking one’s own ways are the only right and proper ways.
2. 4. Allowing parents to stay and pray in the child’s room meets the needs of both parents and child.
3. 1. American Indians may interpret eye contact as rude; they also tend to be comfortable with silences.
4. 3. Islamic Arabs may avoid pork.
5. 1. Nonharmful cultural practices should be allowed.

Chapter 5
1. 3. “Complement” means “something added.”
2. 3. Allopathy, or Western medicine such as is practiced in the United States, is based on scientific research.
3. 4. Ginger, as with all herbs, can interact with other medications.
4. 1, 3, and 5 all use some form of relaxation.
5. 2. It is essential that health care providers are aware of patient use of complementary and alternative medicine to evaluate their safety with conventional therapies and medications.

Chapter 6
1. 1, 5. Sodium is the major cation in the blood and helps maintain serum osmolarity. Sodium is also important for cell function, especially in the central nervous system.
2. 2. Dehydration is associated with poor skin turgor because of loss of water in the tissues and with disorientation because of loss of blood volume in the brain.
3. 4. The older adults have reduced kidney function and may not be able to handle excess fluids.
4. 3. Daily weights are the best way to monitor fluid imbalances. They are easier to monitor accurately than intake and output.
5. 1. Elevating the head of the bed will provide more room for lung expansion and provide the quickest relief for shortness of breath.
6. 1. Daily or every-other-day weights are easy to keep track of at home.
Chapter 7
1. 2. Policies may vary slightly by institution. Always use the policies provided by your workplace.
2. 1 (a man with dehydration requires fluids), 2 (a woman with an eating disorder will benefit from parenteral nutrition), 3 (intravenous [IV] antibiotics may be effective if oral antibiotics have failed), 4 (prolonged vomiting causes fluid and electrolyte loss and requires replacement), 6 (IV diuretics will work the fastest on fluid overload).
3. 1. Site selection should move from distal to proximal on the arm.
4. 2, 5, 6, 1, 3, 8, 9, 4, 7. See Table 7.1.
5. 3. The multiple tourniquet technique will best help visualize veins for cannulation.
6. 2. The patient has signs of an air embolism. The cracked tubing must be clamped, and oxygen will support oxygenation until the registered nurse or physician arrives.
7. 4. Blood products must be administered with sodium chloride to avoid complications.
8. 3. The catheter that is palpable under the skin is the tunneled portion of the catheter.
9. 33:
   \[
   \frac{100 \text{ mL}}{1 \text{ hour}} \times \frac{1 \text{ hour}}{60 \text{ minutes}} \times \frac{20 \text{ gtt}}{1 \text{ mL}} = 33 \text{ gtt/minute}
   \]
10. 83
   \[
   \frac{1000 \text{ mL}}{12 \text{ hours}} = 83 \text{ mL/hour}
   \]

Chapter 8
1. 5, 2, 3, 1, 6, 4. This is the order in the chain of events leading to an infection (Fig. 8.1).
2. 3. Hand hygiene is essential to help prevent infections.
3. 2. Applying lotion to skin, the first line of defense, prevents dryness and cracking.
4. 3. An elevated low-grade temperature when immunocompromised (neutropenia) can be very significant.
5. 1. All patient allergies must be checked to help prevent an allergic reaction.
6. 4. Maintaining a closed urinary drainage system is essential to prevent contamination.
7. 3. Take all medication as ordered to help prevent relapse and development of bacterial resistance.

Chapter 9
1. 3. The sympathetic nervous system (fight or flight) is stimulated to compensate for shock symptoms.
2. 1, 5, 6. Wheezing, urticaria, and bronchospasm are seen specifically in anaphylactic shock.
3. 4. Cerebral hypoxia depresses the central nervous system.
4. 1, 3, 5. When teaching the geriatric patient, include others to reinforce learning, have visible materials in large print, and speak slowly and lower tone to increase understanding of spoken words.
5. 4. Increasing blood pressure indicates the shock is improving.
6. 2. Ineffective tissue perfusion occurs due to shock.
7. Restlessness and confusion indicate a need for oxygen, which is started immediately while other treatment is prepared.
8. 4. These vital signs indicate progressive shock and require immediate intervention.
9. 3. A normal blood pressure would indicate effective treatment for shock.
10. 2, 3, 1. As shock progresses from compensated to decompensated, systolic blood pressure decreases.

Chapter 10
1. 2. Pain is whatever the patient says it is, whenever the patient says it is.
2. 4. Distraction is an effective method when used with medication for pain control.
3. 3. Tolerance is the need for more medication to achieve the same effect. There is no ceiling effect for opioids, so if the patient is still in pain, the dose may need to be increased.
4. 2. Surgery would cause acute nociceptive pain, which will be most appropriately treated with an opioid.
5. 1. Neuropathic pain is most commonly described as shooting, tingling, or shocklike.
6. 3. A valid assessment scale is the best way to quantify pain.
7. 1, 4, 5. According to the World Health Organization ladder, adjuvants are always appropriate in addition to analgesics. They are not intended to substitute for analgesics.
8. 3. The patient will experience the best pain relief with the combination of an opioid and nonopioid.
9. 4. Meperidine should be avoided in older adult patients.
10. 2. Gabapentin must be taken continuously to be effective. Chronic neuropathic pain is not likely to go away, so treatment will be ongoing.
11. 4. A placebo should not be administered except in research studies. The supervisor should be involved in educating the physician.

Chapter 11
1. 1, 5, 6. Malignant tumors are invasive, lack contact inhibition, and have defective communication.
2. 1. The blood cell counts, including the white cell count, will be decreased at the nadir.
3. 4. Choosing a wig before hair loss will make adaptation easier once it occurs.
4. 4. Nonpharmacological methods should be used with, not instead of, medication.
5. 3. Patients with bone cancer are at risk for spinal cord compression, which can cause difficulty walking.
6. 3. The real goal is intact skin. Selections 1, 2, and 4 are interventions.
7. 1. Only patients with 6 months or less to live, who are no longer treating their cancer, are eligible for hospice care.
8. 3. Teach the patient the reason for the isolation. Having a nurse, family member, or another patient in the room would place them at risk for radiation exposure.

Chapter 12
1. 1, 3, 4, 5, 6. All except 2, which can contribute to increasing anxiety and fear, will calm the patient, place the patient in a healthier state, or teach the patient ways to promote recovery.
2. 1. Assisting in data collection is an LPN function; selections 2 and 4 are the physician’s role, and selection 3 is the RN’s role.
3. 4, 5, 6. The LPN may refer questions to the surgeon, read the consent to a patient, and witness the signature of a patient who is informed.
4. 2. Large black-on-white printed materials are most easily seen by the older adult.
5. 1, 5, 6. Controlling pain allows the patient to cough and deep breath more comfortably, which expands the lungs, as does ambulation.
6. 3. Clear lung sounds indicate that the lungs are functioning normally.
7. 1. Tachycardia is a compensatory sign to maintain cardiac output for fluid volume loss, as in hemorrhage.
Chapter 13

1. 1, 2, 3, 5. ABCD and vital signs are part of the primary survey, not chronic illness or deformity, which is part of the secondary survey.
2. 1. Hemorrhaging is controlled by applying pressure at the site.
3. 2. Singed nasal hairs indicate possible inhalation injury from a fire, so the nurse should be alert to possible respiratory complications.
4. 3. The immediate need is to remove the patient from the hot environment to allow other interventions to be effective.
5. 1, 5, 6. Inhaled chlorine is irritating to the respiratory tract, which can cause airway obstruction, dyspnea, and pulmonary edema.
6. 2. Being respectful will gain trust, whereas the other choices will not.
7. 4. The goal is to treat the most critically injured person with the best potential for survival first, which is 4, because patient 3 is unlikely to survive and patients 1 and 2 are not critical and will survive.
8. 3. Airway obstruction can occur in anaphylaxis, which is the most important in ABCs.
9. 3. Shock is a condition of progressively decreasing blood pressure.

\[
\frac{500,000 \text{ units}}{400,000 \text{ units}} = 1.25 \text{ mL}
\]

Chapter 14

1. 3. Integrity versus despair is the developmental stage for those over age 65. Role changes and coping with these losses are typically experienced in this stage.
2. 4. Spiritual distress often occurs with chronic illnesses, along with hopelessness, isolation, and powerlessness.
3. 1. The caregiver is exhibiting behaviors indicating Caregiver Role Strain. Because behaviors have been exhibited, it is past the risk stage.
4. 2. Providing education on the chronic illnesses is most essential for the patient to be able to understand and deal with the illness and achieve a higher level of wellness.
5. 2, 3, 6. Nursing care for a patient who is chronically ill should include encouraging family visits, inclusion of family in teaching, and seeking patient input for plan of care. Education should be increased, patients should set their own goals as able, and socialization with friends should be encouraged.
6. 2, 3, 5, 6. The nurse wants to encourage the patient to verbalize feelings of sorrow by having time to listen, actively listening, sharing relevant information to foster coping, and encouraging hope.
7. 2. The statement "Maybe tomorrow will be a better day" indicates the patient is hopeful and looking to the future, which is a goal for resolving chronic sorrow.

Chapter 15

1. 3. Aging is a maturational process, not a disease, creating the need for individual adaptation because of physical and psychological declines that occur during a lifetime, not a specific age.
2. 4. Shortening in height is caused by water loss in the intervertebral disks of the spinal column with aging.
3. 1, 3, 4. Assessment identifies potential problems for prompt intervention. Gentle bathing preserves skin integrity by, for example, reducing friction during drying and using warm not hot water, which is drying to the skin. Massage stimulates circulation for healthy skin.
4. 2. Offering explanations and active participation with the use of reminders encourages self-care and supports independence for older patients in adhering to a prescribed medication routine.
5. 2. Ischemia from unrelieved pressure can begin to develop in 20 to 40 minutes.
6. 3. Decreased gag reflex and relaxation of lower esophageal sphincter, increasing the risk of aspiration.
7. 1, 3, 4, 5. Adequate fiber and water intake and exercise, including participation in activities of daily living, promote bowel evacuation, whereas some drugs can contribute to constipation.

Chapter 16

1. 4. Wald established the Henry Street Settlement in New York City, which laid the groundwork for establishing home care as a nursing specialty.
2. 1, 2, 3, 4, 6. All are team members except a lawyer.
3. 4. The performance of the skills related to the purpose of the visit must be documented for reimbursement.
4. 2. Organizing the night before a visit will instill confidence in the nurse and the patient during the visit.
5. 1. Infection control is an important function of the home health nurse, and disinfecting the home health bag is important.

Chapter 17

1. 3. Difficulty swallowing and weight loss are evidence that the patient is near death.
2. 4. A durable power of attorney is a person who can make decisions for a patient when the patient is no longer able to. A living will is the document that outlines a patient’s wishes.
3. 1. A good death is possible if the patient’s wishes are followed and the patient is comfortable.
4. 4. There is no one “right” thing to say to a grieving person. Listening is important.
5. 2, 4. Scopolamine and morphine both have anticholinergic properties that will dry secretions.
6. 1, 2, 4, 5. Positioning, comfort measures, and being present are appropriate. Treatments to cure disease or prolong life are inappropriate.
7. 3. Clean the patient and make him presentable for the family. Paperwork can be done later.
8. 3. Spending a few minutes with the wife is the most caring; eventually the bed must be cleaned for the next patient.
9. 1. A patient can change his mind at any time.

Chapter 18

1. 4. Artificially acquired active immunity is provided by a vaccine.
2. 1. Older adults should receive an influenza vaccine.
3. 1. A splenectomy may reduce immune function.
4. 3. Painful enlarged lymph nodes are associated with inflammation and infection.
5. 2. For positive ELISA results, which may indicate HIV infection, results must be confirmed by another test, usually the Western blot.
6. \[
\frac{200 \text{ mg}}{125 \text{ mg}} \times 5 \text{ mL} = 8 \text{ mL}
\]

Chapter 19

1. 3. Viral illnesses and exposure to various chemicals and environmental substances can alter the immune system and its response to previously benign stimuli.
2. 2. It is a chronic progressive inflammatory disease of large peripheral joints.
3. 1. Glossitis is a sign of pernicious anemia.
4. 3. A Schilling test requires 24-hour collection of urine.
5. 1, 2, 3, 4, 6. All are used for allergic rhinitis except anticholinergics.
Chapter 20

1. HIV is transmitted from human to human only through infected blood, through sexual secretions, and from an infected mother to her unborn baby or to her infant via breast milk.

2. 1, 3, 5. There is no known cause for primary hypertension as working effectively to control the edema.

3. 2, 5. Distended jugular veins in semi-Fowler’s position and ankle edema are signs of HF.

4. 4. A healthy diet can control blood pressure and includes eating fresh or frozen fruits and vegetables, reading food labels to make healthy choices, and being aware of safe salt substitutes.

5. 3. Prehypertension is 120–139/80–89 mm Hg and should be followed up in 1 year.

6. 2. Elevated blood pressure.

7. 1, 3, 5. There is no known cause for primary hypertension as there is for secondary.

8. 3, 5, 6. Selection 1 is not done because the patient may have difficulty swallowing, and for selection 2, an IV is needed for medication administration.

9. 2. Sun exposure should be avoided and long sleeves, pants, a hat, and sunscreen worn due to photosensitivity.

10. 1. A classic symptom of systemic lupus erythematosus is a red rash across bridge of nose that resembles a butterfly.

Chapter 21

1. 4. Tobacco use can be modified through smoking cessation.

2. 1. Decreased arterial flow to the extremity is reflected in a slower capillary refill.

3. 2. A gait or walking belt should be used for patients who risk falling, which someone with orthostatic hypotension could be.

4. 4. On bedrest, edema will be found in dependent areas such as the sacrum.

5. 1, 4, 5, 6. Patient education: Types of allergies are asked because a dye is used that causes a flushing sensation; firm pressure is applied afterward to prevent bleeding, and therefore ambulation and flexion are not allowed for several hours.

6. 2. Fiber helps prevent constipation and straining during bowel movements, which reduces cardiac workload.

7. 3. Warfarin (Coumadin) affects clotting and is usually stopped before surgery to prevent bleeding issues.

Chapter 22

1. 1, 3, 5. There is no known cause for primary hypertension as there is for secondary.

2. 1. Reducing weight can help control blood pressure.

3. 2. Elevated blood pressure.

4. 4, 5, 6. A healthy diet can control blood pressure and includes eating fresh or frozen fruits and vegetables, reading food labels to make healthy choices, and being aware of safe salt substitutes.

5. 3. Prehypertension is 120–139/80–89 mm Hg and should be followed up in 1 year.

6. 2. The patient needs immediate treatment for a blood pressure that elevated, so the nurse calls 911.

7. 2, 5. Distended jugular veins in semi-Fowler’s position and ankle edema are signs of HF.

Chapter 23

1. 3. Angina indicates cardiac ischemia and requires prompt intervention.

2. 2. Symptoms are often not present in MVP.

3. 1. In commissurotomy, the valve flaps that have adhered to each other and closed the opening between them, known as the commissure, are separated to enlarge the valve opening.

4. 4. Mechanical valves require lifelong anticoagulation to prevent emboli, unlike biological valves, which are less likely to create emboli.

5. 1. A streptococcal infection is a bacterial infection treated with the antibacterial agent penicillin.

6. 2. Dyspnea can indicate heart failure, which is a complication of cardiomyopathy.

7. 1, 4, 5, 6 indicate a blood clot. Selections b and c are seen with heart failure.

8. 3. INR is checked to determine if it is safe to give warfarin (Coumadin).

Chapter 24

1. 2. Hypertension is a modifiable risk factor for cardiovascular disease, whereas the others are nonmodifiable.

2. 1. Fatigue is an atypical symptom in the absence of chest pain.

3. 2. Coronary artery bypass grafting is done to increase blood flow to the myocardium.

4. 4. Place one tablet under the tongue, and if after 5 minutes pain is not relieved in presence of MI symptoms, don’t wait—call 911 because nitroglycerine alone will not treat an MI.

5. 3. Intermittent claudication (calf pain with exertion) occurs with peripheral arterial occlusive disease.

6. 3. Trental (Pentoxifylline) relieves claudication by decreasing blood viscosity, which increases blood flow in the extremities.

7. 3. The patient should keep legs down to promote arterial blood flow to distal extremities.

Chapter 25

1. 2, 5, 1, 3, 4. The SA node is the primary pacemaker and fires the impulse, which then travels across the atria, to the AV node, bundle of HIS, and Purkinje fibers.

2. 1. With a systematic method, it is more difficult to miss abnormalities.

3. 3. Defibrillation is used for initial treatment of pulseless ventricular tachycardia to reset the heart’s rhythm.

4. 3. Teaching for pacemaker care includes avoiding strong electromagnetic devices that could interfere with the pacemaker settings.

5. 2. The patient should be assisted onto a gurney (stretcher) to reduce cardiac workload, promote safety, and quickly begin treatment.

6. 4. Bradycardia is the term for a pulse of 59 beats per minute or less.

7. Two tablets should be given per dose.

Chapter 26

1. 2. In heart failure, the heart cannot pump enough blood to meet the body’s oxygen needs.

2. 1. Hypertension contributes to left-sided heart failure because the left ventricle must pump against increased pressure in the aorta from the hypertension.

3. 1. A diuretic should be taken in the morning to prevent diuretics, the patient rises slowly.

8. 1. To prevent falls from orthostatic blood pressure when on diuretics, the patient rises slowly.

Appendix C  Answers to Review Questions

Chapter 27
1. 2. This is a low platelet count; platelets are essential to the clotting process.
2. 1. New-onset petechiae are associated with bleeding or clotting disorders.
3. 2. Indicates more teaching is needed. The space between the fingers or toes, not the groin, is used for lymphangiography.
4. 1, 2, 4. Matching the blood to the order and the patient is essential. Baseline vital signs help identify reactions.
5. 4. Fever and chills could signify a febrile or a hemolytic reaction. For either, the unit should be stopped immediately and the physician contacted.

Chapter 28
1. 2. Anemia means less hemoglobin to carry oxygen to tissues, causing dyspnea.
2. 3. Strenuous activity increases oxygen demand, which can cause cells to sickle.
3. 4. Disseminated intravascular coagulation uses up clotting factors, which leaves the patient at risk for bleeding.
4. 1. A patient with hemophilia should avoid injury; contact sports are too dangerous.
4. A patient with leukemia has poor immune function and should not be around someone with a runny nose.
5. 1, 4, 6. Intramuscular injections, aspirin, nonsteroidal anti-inflammatory drugs, and walking without shoes or slippers all increase the risk of injury or bleeding in a patient with thrombocytopenia.
7. 1, 4, 6. Intramuscular injections, aspirin, nonsteroidal anti-inflammatory drugs, and walking without shoes or slippers all increase the risk of injury or bleeding in a patient with thrombocytopenia.
8. 1715
9. 1. Neutropenia reduces ability to fight infection; temperature or loss.
10. 4. A high abdominal incision makes deep breathing and coughing difficult, increasing the risk of respiratory complications.

Chapter 29
1. 4. 2.5 packs per day × 10 years = 25 pack-years.
2. 2. Wheezes are violin-like sounds made by narrowed airways.
3. 4. A normal SpO2 is 95% to 100%. An SpO2 less than 90% is cause for concern.
4. 3, 5, 2, 1, 4.
5. 2. This delivers the most medication to the lungs.
6. 3. Repositioning the mask can redirect the air, while keeping the continuous positive airway pressure (CPAP) intact.

Chapter 30
1. 2. Influenza is caused by a virus. Antibiotics are not effective against viruses.
2. 1. Airway is always a priority, especially after surgery that affects the airway.
3. 4. Antiviral agents are only effective if they are started within 48 hours of symptom onset.
4. 4. Sitting and leaning forward allows the nurse to observe the amount of blood and prevents aspirating or swallowing of blood.
5. 1, 2, and 5 all help reduce transmission of influenza.
6. 1. The patient with a laryngectomy will suffocate if a finger is placed over the stoma.

Chapter 31
1. 3. LTBI is a latent, not active, infection.
2. 2. Damaged alveoli and air trapping cause diminished breath sounds.
3. 4. Biopsy is always the most definitive test for cancer.
4. 3. Pleurodesis is painful; a pain medication should be administered.
5. 3. Wheezes and crackles can signify sputum that needs to be coughed up.
6. 1. Hypoxia can cause confusion and agitation.
7. 2. Diaphragmatic breathing can help make the breathing pattern more effective.
8. 1. SpO2 is the best measure of gas exchange.

Chapter 32
1. 2. Pain from a ruptured appendix is located in the right lower quadrant.
2. 4. Increasing dietary fiber will help regulate normal bowel function.
3. 1. Bowl sounds heard at an irregular rate every 5 to 15 seconds are normal.
4. 3. Lightly depress the abdomen, not more than 0.5 to 1.0 inch.
5. 2. Dehydration must be prevented to avoid a barium impaction.
6. 3. 4. Salem nasogastric tubes are larger bore tubes that are not used for feeding or longer term use.
7. A chest x-ray is the only accurate way to verify correct placement of the feeding tube.
8. 4. Hyperglycemia may occur due to the high dextrose concentration in parenteral nutrition.

Chapter 33
1. 2. The priority is to provide nourishment and correct electrolyte imbalance, which can be life threatening.
2. 3. A body mass index of 31 is defined as obese.
3. 4. Topical tetracycline can aid healing canker sores.
4. 3. Helicobacter pylori, a bacterium, is the most common cause of peptic ulcers.
5. 4. H2 antagonists inhibit secretion of gastric acid.
6. 3. To protect the airway, the patient must be placed onto his or her side.
7. 2. Fluid and fat intake promote rapid gastric emptying.

Chapter 34
1. 1. Report findings because symptoms of dehydration are present along with elevated vital signs.
2. 2. Laxatives should be used only occasionally to prevent dependence and complications.
3. 1, 2, 4, 5. Control pain and promote lung expansion with activity or coughing and deep breathing.
4. 1. Fresh fruit is high in fiber and would promote diarrhea.
5. 4. Coughing is contraindicated to prevent damaging the repair, but deep breathing should be done.
6. 3. This is the only selection that does not contain a type of grain that must be avoided.
7. 1, 2, 3, 4. All but edema are a priority to detect pain, dehydration, infection, or shock.
8. 1. Check vital signs for stability as the black tarry stool indicates bleeding above or within the small bowel.
9. 3. A high-fat, low-fiber intake increases the risk of colon cancer.
10. 1. A dusky color indicates impaired circulation and requires immediate medical treatment to restore blood flow.
11. 2. 10 mL

Chapter 35
1. 2. Vitamin K is needed for blood clotting, so a low level increases the risk of bleeding.
2. 3. Sedatives are potentially toxic to the cirrhosis patient due to impaired hepatic metabolism of these medications.
3. 3. Headache, nausea, and flu-like symptoms are symptoms of hepatitis A infection.
Appendix C Answers to Review Questions

Chapter 40
1. 1. Insulin is not available in pill form at this time. The patient needs additional education.
2. 126.
3. 2. Frequent urination can be a sign of diabetes.
4. 4. Extra socks are the safest way to warm feet that are at risk for injury.
5. 3. Tight control of blood glucose levels is the best way to prevent complications. Selections 1, 2, and 4 are also helpful, but are not the best way.
6. 4. Includes a balance of complex carbohydrates, fats, and protein. Selection 1 is high fat, low carbohydrate. Selections 2 and 3 have minimal fat or protein.
7. 1. 48 is below normal and is considered hypoglycemia.
8. 1. Sliding scale insulin may be needed during times of stress or illness.
9. 2. Small, frequent, low-carbohydrate meals will help prevent fluctuations in blood glucose.

Chapter 41
1. 2. Young men are at risk for testicular cancer, and so should be taught testicular self-examination.
2. 3. Lying flat will reduce discomfort from the carbon dioxide used for insufflation.
3. 1. The National Institutes of Health recommends 1200 mg calcium and 600 international units vitamin D for women ages 51 to 70.
4. 4. Gravida 4 = fourth pregnancy, Para 2 = 2 births, and A1 = 1 abortion (spontaneous)
5. 3. The LPN/LVN typically would not perform a genital assessment but would prepare the patient and be present during the examination.

Chapter 42
1. 3. Mastalgia can be broken down as mast—breast + algia—pain.
2. 2. Bleeding again after menopause is always cause for concern.
3. 4. Bradycardia and falling blood pressure are signs that the vagus nerve has been stimulated.
4. 1, 3. Atropine is an anticholinergic agent that will reverse the cholinergic response initiated by vagal stimulation. Epinephrine is an adrenergic agonist that will raise heart rate and blood pressure.
5. 2. Relaxation exercises and warm compresses can help relax the patient and reduce the perception of pain, when used with medication.
6. 3. Because of compromised circulation in the affected arm, needlesticks and blood pressure measurements should be avoided.
7. 2. Because the ovaries are removed in a BSO, the patient should expect to experience menopause.
8. 240. The patient should eliminate at least 30 mL per hour times 8 hours = 240 mL.
9. 1. Douching is ineffective because sperm may already be out of reach. It also may push sperm further upward.

Chapter 43
1. 3. Benign prostatic hyperplasia is not cancer, but it must be treated. Telling a patient not to worry is inappropriate.
2. 3. Viagra (sildenafil) is a vasodilator and can cause priapism.
3. 1. A B&O suppository will reduce bladder spasms, which often cause pain after TURP.
4. 2. Cleaning is important but be sure to replace the foreskin reach. It also may push sperm further upward.
5. 2. Herbal remedies should never be tried without consulting the HCP. The patient needs additional education.
6. 1. Reflecting back and asking the patient if he would like to talk more will identify if there is a concern that should be followed up by a physician or care provider.
Appendix C  Answers to Review Questions

Chapter 44
7. 1, 4. Varicocele is like a varicose vein in the scrotum. It can cause pain and infertility.
8. 4. Nicotine and alcohol use can interfere with male fertility.

Chapter 45
1. 3, 5, 6. Exercise and diet are important to maintain bone health. Collecting data about them is the first step in planning interventions for the disease.
2. 4. Pallor of an extremity is not a normal finding and may indicate circulatory problems so the HCP is notified.
3. 1. Ask if there is any metal or a pacemaker in the patient’s body to allow the HCP to determine if it is safe to do an MRI.
4. 2. Notify the surgeon because circulation in the extremity may be compromised and require immediate treatment.
5. 2, 5 The patient usually is nil per os (NPO) after midnight the night before surgery in the morning. Patients having general anesthesia are taught coughing and deep-breathing exercises to promote lung expansion and prevent lung complications before surgery so they understand them when prompted to do them after surgery. (1) No food is eaten close to surgery time. (2, 4) are responsibilities of the physician. (6) Straight-leg raises are not taught if surgical repair is performed because activity restrictions may be ordered.

Chapter 46
1. 4, 1, 3, 5, 2. Transfer and positioning cast to prevent pressure points by palming the cast while moving it, placing it on a pillow and leaving it uncovered to air dry is the initial priority; next data collection of circulation, sensation, and mobility status to detect problems with extremity or cast that require prompt action; and then vital signs before analgesic administration to determine stability.
2. 2. Agency protocol specifies pin care.
3. 1, 5. Hand hygiene and wearing sterile gloves to apply a new dressing is essential.
4. 3. Exercise can help prevent osteoporosis.
5. 1. Pain is a classic symptom of Paget’s disease. (Remember, P = P).
6. 3. Excessive uric acid is formed in gout.
7. 2. Maintaining ideal body weight will reduce wear and tear on the knee.
8. 2. Maintain legs in abduction to prevent dislocation of the hip.
9. 3. Stump dressings should be monitored for bleeding.
10. 4. An absent left pedal pulse may be due to circulatory impairment caused by the fracture and requires immediate treatment.
11. 4. Notify the HCP because the patient may be developing compartment syndrome, an emergency condition.
12. 0.5 mL

Chapter 47
1. 1, 2, 3, 4, 5. Verbal response, is part of the Glasgow coma scale.
2. 4. The trigeminal nerve is a sensory nerve supplying the face.
3. 2. Decreasing level of consciousness may be caused by increasing intracranial pressure or other serious complications, and should always be reported immediately.
4. 2, 3, 4, and 6 are all normal effects of aging.
5. 4. An angiogram uses x-ray or other imaging following injection of dye.
6. 2. Fluids help the kidneys excrete the dye.
7. 3. High-top tennis shoes keep the feet in functional positions.

Chapter 48
1. 1. A sore throat is caused by a virus or bacterium, which can spread to cause meningitis.
2. 2. Darkening the room will help relieve photophobia, and analgesics reduce pain.
3. 3. A headache diary provides the best data for diagnosis.
4. 3. The patient will be in a deep postictal sleep and can eat when awake.
5. 3, 1, 4, 2. The patient should be assisted to lie down before the seizure starts; safety should be maintained; the patient will sleep after the seizure; document last.
6. 2, 3, 4. Fever and headache could indicate encephalitis or meningitis. Cranectomy and brain tumor can be associated with brain swelling.
7. 2. Elevating the head of the bed can reduce intracranial pressure.
8. 3. This could be a sign of autonomic dysreflexia.
9. 1. Tucking the chin may help guide the food into the esophagus.
10. 2. This validates her feeling of loneliness in a nonthreatening way.

Chapter 49
1. 3, 5, 6. Diabetes, high cholesterol, and obesity are all treatable to reduce the risk of stroke.
2. 1, 2, 4 can all help reduce aspiration. Straws and placing food on the affected side (where the patient may not be aware of it) increase risk.
3. 4. Thrombolytic therapy must be given within 4.5 hours to reverse stroke symptoms and reduce the risk of complications.
4. 3. Receptive aphasia is difficulty receiving, or understanding, language, so use of gestures may help with communication needs.
5. 1. The patient may be experiencing unilateral neglect or visual deficits. Turning the plate and observing can help identify the problem.
6. 3. Call for help immediately. The patient could be experiencing an extension of the bleed or ischemic area.

Chapter 50
1. 3. Anticonvulsants help relieve nerve pain.
2. 4. Amyotrophic lateral sclerosis causes weak muscles. If the respiratory muscles are affected, breathing (and singing) may be compromised.
3. 1. Advance directives will allow the patient to have his wishes recorded.
4. 3. Assessment and maintenance of respiratory function is a nursing priority.
5. 1, 2, 4, and 5 help with symptoms related to paralysis. Selections 3 and 6 are interventions for trigeminal neuralgia.
6. 2. Soft foods are easier to chew and less tiring.
7. 4. Ability to perform activities of daily living and effective breathing are signs that muscle strength is adequate.

Chapter 51
1. 2, 1, 3, 4: cornea, aqueous humor, lens, vitreous humor.
2. 4. Comparing the patient’s visual fields with your own assesses visual fields.
3. 2. Those with a hearing loss are often irritable or sensitive during interpersonal relations because of their inability to hear and interact with others.
4. 3. Having regular hearing evaluations helps ensure ear health.
5. 1. Ensuring patient safety to prevent injury is essential.
6. 4. Aspirin can be toxic to the ears is true, which shows understanding of teaching.
7. 1, 2, 3. Gloves, gown, goggles (if splashing is anticipated) are used in contact isolation for this nonsterile procedure, whereas a mask is used for respiratory isolation.
8. 3. Tinnitus occurs with aspirin toxicity.

Chapter 52
1. 3. Otosclerosis is hardening of the stapes from new bone growth.
2. 2. A refractory error requires corrective lenses to see clearly.
3. 1. Pain is experienced with an external ear infection.
4. 1. Because the pupils are dilated, the eyes must be protected from bright light.
5. 2. After pneumatic retinopexy, the patient is educated on positions to keep the air bubble in place.
6. 3, 5. Atropine and hydroxyzine are mydriatics, which are contraindicated in acute angle-closure glaucoma to prevent increasing eye pressure.
7. 1. Furosemide (Lasix) can cause hearing loss.
8. 4. Loss of central vision occurs with macular degeneration.
9. 3. Ménière’s disease can cause vertigo, which could result in injury.
10. 2. With presbycusis, there is an inability to decipher high-frequency sounds, so a lower voice pitch is helpful.
11. 4. Mydriatics such as anticholinergics and antihistamines (diphenhydramine) are contraindicated in acute angle-closure glaucoma.

Chapter 53
1. 3. Ointments and creams should be applied to clean, moist skin, so after a bath is an appropriate time.
2. 2, 3, 5. Skin is protected in a warm, not hot bath, using gentle soap or prescribed agent. A warm room prevents chilling.
3. 3. A vesicle is a fluid-filled lesion.
4. 1. A severe allergic reaction may require resuscitation.
5. 2. Occlusive dressings must be removed 12 of every 24 hours to prevent skin atrophy, folliculitis, or systemic absorption of medication.

Chapter 54
1. 1, 2, 4, and 5 can all help itching and reduce scratching. Tepid, not hot, baths with oatmeal are encouraged.
2. 3. Exposure to ultraviolet rays is the major cause of skin malignancies.

Chapter 55
1. 2. Deep partial-thickness burns are associated with pink to light red or white skin, blisters, and pain.
2. 1. Lavage with water for 20 minutes for all chemical burns, along with simultaneous removal of contaminated clothing. Neutralizing a chemical takes too much time.
3. 3. The trunk is 18% front, 18% back, and each arm is 9%.
4. 3, 4, 5. Circulation must be monitored. Escharotomy may be indicated. Elevation promotes venous return.
5. 4. PaO2 88 mm Hg is the only normal value listed.

Chapter 56
1. 1. No one is happy and smiling all the time. It is not an expected behavior and follow-up is indicated.
2. 1, 3, 5, and 6 can all reflect level of mental health.
3. 2. Physical causes of symptoms should always be ruled out before making a mental health diagnosis.
4. 3. Rationalization is using logical-sounding excuses to cover up true thoughts.
5. 3. A therapeutic milieu is an environment that provides containment, support, structure, involvement, and validation.
6. 4. Medications can help manage symptoms so patients can engage in therapies.
7. 1. Honest communication is a productive behavior. Selections 2, 3, and 4 reflect defense mechanisms.
8. 4. This selection demonstrates therapeutic communication and active listening.

Chapter 57
1. 4. A depressed patient is at risk for suicide and must be kept safe.
2. 3. Obsessions are repetitive thoughts, and compulsions are related actions.
3. 1. Anticholinergic agents help restore the balance of neurotransmitters to prevent extrapyramidal side effects.
4. 4. The patient has posttraumatic stress disorder and needs calm reorientation until the episode is over.
5. 3. Checking vital signs verifies whether there is a real physical cause for the symptoms and also reassures the patient.
6. 2. Orient the patient to reality, then redirects to another activity.
## Medical Abbreviations

Although it is still important to know medical abbreviations, many can increase risk of errors. Check [www.jointcommission.org](http://www.jointcommission.org) for a list of abbreviations to avoid.

### Prefixes, Suffixes, and Combining Forms

- **a-**, **an-**. Without; away from; not
- **ab-**, **abs-**. From; away from; absent
- **abdomi-**, **abdomino-**. Abdomen
- **ad-**. Toward; in the direction of
- **aden-**, **adeno-**. Gland
- **adip-**, **adipo-**. Fat
- **-aemia**. Blood
- **-emia**. Vomiting
- **ef-**, **es-**, **ex-**, **exo-**. Out
- **enteri-**, **entero-**. Intestine
- **ep-**, **epi-**. Upon; over; at; in addition to; after
- **erythri-**, **erythro-**. Red
- **eury-**. Broad
- **ex-**. Out; away from; completely
- **extra-**. Out; outside of; without
- **factient**. Causing; making happen
- **ferri-**, **ferro-**. Iron
- **fluor-**. Flow
- **fore-**. Before; in front of
- **form-**. Shape
- **fugue**. To expel; to drive away; fleeing
- **gaster-**, **gastro-**, **gastr-**, **gastro-**. Stomach
- **gen-**. Producing; forming
- **gen-**, **gene-**, **genesis**, **genetic**, **genic**. Producing; forming
- **gloso-**. Tongue
- **gluc-**, **gluco-**, **glyco-**. Sugar; glycerol or similar substance
- **gyn-**, **gyneco-**, **gyno-**. Woman; female
- **hemi-**. Half
- **hem-**, **hema-**, **hemato-**, **hemo-**. Blood
- **heret-**, **hetero-**. Other; different
- **hizo-**. Tissue
- **homo-**. Same; likeness
- **histo-**. Tissue
- **heter-**, **hetero-**. Other; different
- **hepat-**, **hepato-**. Liver
- **hemi-**. Half
- **hepat-, hemat-, hemo-**. Blood
- **hyper-**. Above; excessive; beyond
- **hyster-**, **hystero-**. Uterus
- **-ia**. Condition; status, process; abnormal
- **-asis**. SEE -iasis
- **iatric**. Medical; medicine profession; physicians
- **in-**. In; inside; within; intensive action; negative
- **infra-**. Below; under; beneath; inferior to, after
- **inter-**. Between; in the midst
- **infra-**, **intro-**. Within; in; into
- **ipsi-**. Same
- **irid-**, **irido-**. Iris
- **ism-**. Condition; theory
- **iso-**. Equal
- **itis**. Inflammation of
- **kera-**, **kerato-**. Horn; horn substance; cornea
- **kolp-**, **kolo-**, **colpo-**. Vagina
- **kypho-**. Humped
- **leuk-, leuko-**. White; colorless; related to leukocyte
- **lip-**, **lipo-**. Fat
- **lute-, lith-, litho-**. Stone; calculus
- **-logia, -logy**. Science; study of
- **lumbo-**. Loins
- **lysis**. 1. Setting free; disintegration; 2. In medicine, reduction of; relief from
- **macro-**, **macro-**. Large; long
- **mal-**. Ill; bad; poor
- **med-**, **medi-**, **medio-**. Middle
- **mega-**, **megalo-**. Large; of great size
- **megalia, -megaly**. Enlargement of a body part
- **melan-**, **melano-**. Black
- **mening-, meningio-**. Meninges
- **meter**, **Measure**
- **metro-**, **metro-**. Uterus
- **micro-**, **micro-**. Small
- **mon-, mono-**. Single; one
- **muc-, muc-, muco-, myxa-, myxo-**. Mucus
- **multi-**. Many; much
- **musculo-**, **musco-**. Muscle
- **my-**, **myo-**. SEE musculo-
- **myel-, myelo-**. Myel; myelo-
- **myel-, myelo-**. Bone marrow
- **naso-**. Nose
- **necr-, necro-**. Death; necrosis
- **neo-**. New; recent
- **neph-, nephra-, nephr-**. Kidney
- **nerv-, neur-, neuro-**. Nerve; nervous system
- **non-**. No
- **normo-**. Normal; usual
- **oculo-**. Eye
- **-ode, -oid**. Form; shape; resemblance
- **odynia, odyno-**. Pain
- **olig-, oligo-**. Few; small
- **-ology**. Science; study of
- **oma**. Tumor
- **onco-**. Tumor; swelling; mass
- **oo-**, **ovi-**, **ovo-**. Egg; ovum
- **ophor-, ophoro-**, **ophor-**. Ovary
- **ophthalmo-**, **ophthalmalmo-**. Eye
- **opial, Vision**
- **optico**, **opto-**. Eye; vision
- **orch-, orchid-, orchido-**. Testicle
- **orth-**, **ortho-**. Straight; correct; normal; in proper order
- **os-**. Mouth; bone
- **-osis**. Condition; status; process; abnormal increase
- **oste-, osteo-**. Bone
- **ostomosis, -ostomy, stomosis, -stomy**. A created mouth or outlet
- **ot-, oto-**. Ear
- **otomy**. Cutting
- **ous**. 1. Possessing; full of; 2. Pertaining to
- **pan-**. All; entire
- **para-**, **para-**. 1. Prefix; near; alongside of; departure from normal; 2. Suffix: Bearing offspring
Appendix E  Prefixes, Suffixes, and Combining Forms

- path-, patho-, -pathic, -pathy.  Disease; suffering
- ped-, pedi-, pedo-.  Foot
- -penia.  Decrease from normal; deficiency
- peri-.  Around; about
- perineo-.  Perineum
- phaco-.  Lens of the eye
- phag-, phago-.  Eating; ingestion; devouring
- -phil, -philia, -philic.  Love for; tendency toward; craving for
- phlebo-.  Vein
- -phobia.  Abnormal fear or aversion
- photo-.  Light
- phren-, phreno-, -phrenia.  Mind; diaphragm
- -phylaxis.  Protection
- -plasia.  Growth; cellular proliferation
- plasm-, -plasm.  1. Prefix: Living substance or tissue; 2. Suffix: To mold
- -plegia.  Paralysis; stroke
- pneumo-.  Breath; breathing
- pneum-, pneuma-, pneumato-.  Air; gas; respiration
- -poiesis, -poietic.  Production; formation
- poly-.  Much; many
- post-.  After
- pre-.  Before; in front of
- presby-.  Old age
- pro-.  Before; in behalf of
- proct-, procto-.  Anus; rectum
- pseud-, pseudo-.  False
- psych-, psycho-.  Mind; mental processes
- pulmo-.  Lung
- py-, pyo-.  Pus
- pyro-.  Heat; fire
- ren-, reno-.  Kidneys
- retro-.  Backward; back; behind
- rheo-, (r)rhea.  Current; stream; to flow; to discharge
- rhino-.  Nose
- -(r)rhage, -(r)rhagia.  Rupture; profuse fluid discharge
- -(r)rhaphy.  A suturing or stitching
- salping-, salpingo-.  Auditory tube; fallopian tube
- sclero-.  Hard; relating to the sclera
- -scopy.  Examination
- semi-.  Half
- sero-.  Serum
- somat-, somato-.  Body
- sperma-, spermat-, spermato-.  Sperm; spermatozoa
- steno-.  Narrow; short
- -stomosis, -stomy.  SEE -ostomosis
- sub-.  Under; beneath; in small quantity; less than normal
- super-.  Above; beyond; superior
- supra-.  Above; beyond; on top
- tachy-.  Swift; rapid
tel-, tele-.  1. End; 2. Distant; far
tendo-, teno-.  Tendon
- thorac-, thoraci-, thoraco-.  Chest; chest wall
- thrombo-.  Blood clot; thrombus
- thyro-.  Thyroid gland; oblong; shield
- -tomy.  Cutting operation; excision
- top-, topo-.  Place; locale
tox-, toxi-, toxico-, toxo-, -toxic.  Toxin; poison; toxic
- tracheo-.  Trachea; windpipe
- trans-.  Across; over; beyond; through
- -tropin.  Stimulation of a target organ by a substance, esp. a hormone
- tympano-.  Eardrum; tympanum
- ultra-.  Beyond; excess
- -uria.  Urine
- uter-, utero-.  Uterus
- vaso-.  Vessel (e.g., blood vessel)
- veno-.  Vein
- ventro-, ventr-, ventri-.  Abdomen; anterior surface of the body
- vertebro-.  Vertebra; vertebrae
- vesico-.  Bladder; vesicle

Glossary

ablation: (uh-BLAY-shun) Removal of part, pathway, or function by surgery, chemical electrosurgery, or radio-frequency.

abrasion: (ah-BRAY-zun) A scraping away of skin or mucous membrane as a result of injury or by mechanical means.

abuse: (uh-BYOOS) Misuse; excessive or improper use. May refer to substances or individuals.

accommodation: (uh-KOM-uh-DAY-shun) A reflex action of the eye for focusing.

acids: (as-ih-DOH-siss) An actual or relative increase in the acidity of blood caused by an accumulation of acid or a loss of base.

acquired immunodeficiency syndrome (AIDS): (uh-KWHY-erd IM-yoo-noh-de-FISH-en-see SDROH-muh) Suppression or deficiency of the cellular immune response, acquired by exposure to human immunodeficiency virus (HIV).

active immunity: (AK-tiv im-YOOH-nih-tee) Acquired immunity attributable to the presence of antibodies or of immune lymphoid cells formed in response to antigenic stimulus.

activities of daily living (ADLs): (ak-TIV-ih-tees of DAY-lee LIH-ving)

Those activities and behaviors that are performed in the care and maintenance of self (e.g., bathing, dressing, eating).

acupuncture: (ak-yoo-PUNG-k-chur)

Technique using needles inserted at specific points to create anesthesia or treat conditions.

acute coronary syndromes: (ah-KUET KOR-un-nah-hee SROYN-dromeh) Group of conditions, including unstable angina, non-Q-wave myocardial infarction, and ST segment elevation myocardial infarction, caused by a lack of oxygen to the heart muscle.

acute pulmonary hypertension: (ah-KUET TULL-muh-NAIR-cee HIGH-purr-TEN-shun) An excessive buildup of pressure in the pulmonary arteries caused by sudden obstruction of the pulmonary artery.

acute pulmonary edema: (ah-KUET TAV-shun) Adjustment to changes in internal or external conditions or circumstances; coping.

addiction: (uh-DIK-shun) Psychological dependence characterized by drug seeking and craving for an opioid or other substance for effects other than the intended purpose of the substance.

adjunct: (ADD-junkt) An addition to the principal procedure or course of therapy.

adjuvant: (ad-JOO-vant) Something that assists something else, such as a second form of treatment added to treat a disease.

administrative laws: (ah-MIN-ih-STRAY-tiv LAWZ) Establish the licensing authority of the state to create, license, and regulate the practice of nursing.

adnexa: (ad-NECK-sah) Appendages or accessory organs.

advance medical directive: (ad-VANS MED-ik-uh-dur-EK-tiv) A set of documents (living will and durable power of attorney) that explain a person’s end-of-life wishes and direct care when the patient is no longer able to do so.

adventitious: (ad-ven-TI-shus) Abnormal or extra; often refers to extra breath sounds, such as wheezes or crackles.

advocate: (ADD-vuh-kut) Someone who makes sure a person’s wishes are adhered to; someone who represents the best interests of the patient.

aerobic: (air-Oh-bick) Living only in the presence of oxygen.

affect: (AF-feckt) Emotional tone.

afterload: (AFF-ter-lodh) The forces impeding the blood flow out of the heart (vascular pressure, aortic compliance, blood mass, and viscosity).

agene sis: (ay-JEN-uh-siss) Failure of an organ or part to develop or grow.

agonist: (AG-un-ist) A type of opioid that binds to opioid receptors in the central nervous system to relieve pain.

akinesia: (ah-kihn-ee-see-ah) Absence or loss of the power of voluntary movement.

alkalosis: (al-ka-LOH-siss) An actual or relative decrease in the acidity of blood caused by loss of acid or accumulation of base.

allopatic: (AL-oh-PATH-ik) Method of treating disease with remedies that produce effects different from those caused by the disease.

alopca scia: (AL-oh-pee-shee-ah) The loss of hair from the body and the scalp.

amenorrhea: (ay-MEN-uh-REE-ah) Absence or suppression of menstruation. Amenorrhea is normal before puberty, after menopause, and during pregnancy and lactation.

amputation: (am-pew-TAY-shun) The removal of a limb or other appendage or outgrowth of the body.

anaerobic: (AN-air-ROH-bik) Able to live without oxygen.

analgesic: (AN-uhhl-JEE-zik) A drug that relieves pain.

anaphylactic shock: (AN-uhhl-LAK-tik SHAWK) Systemic reaction that produces life-threatening changes in the circulation and bronchioles.

anaphylaxis: (AN-uhhl-LAK-siss) A sudden severe allergic reaction to an allergen.

anastomose: (uh-NAS-uh-MOHSS) To surgically connect two parts.

anemia: (uh-NEE-mee-ya) A condition in which there is reduced delivery of oxygen to the tissues as a result of reduced numbers of red cells or hemoglobin.

anergy: (AN-er-je) Diminished ability of the immune system to react to an antigen.

anesthesia: (AN-ee-THEE-zee-uh) Lack of feeling or sensation; artificially induced loss of ability to feel pain.

anergia: (AN-uh-reh-zihm) A sac formed by the localized dilation of the wall of an artery, a vein, or the heart.

angina pectoris: (AN-jee-nuh PAY-kur-izm) Severe pain and pressure in the chest caused by insufficient supply of blood and oxygenation to the heart.

angiodema: (AN-guh-dee-MAY-uh) A localized edematous reaction of the deep dermis or subcutaneous or submucosal tissues appearing as giant wheals.

anion: (AN-eye-uhn) Electrolyte that carries a negative electrical charge.

anisoctasia: (AN-uh-reh-KAH-suh) Absence or loss of the power of voluntary movement.

ankylosing spondylitis: (ANG-kuhl-LOH-sing SPON-duh-LEYE-iss) Inflammatory disease of the spine causing stiffness and pain.

annuloplasty: (AN-yoo-loh-PLAS-tee) Repair of a cardiac valve.

anorexia: (AN-uhhl-REE-k-see-ah) Absence or loss of appetite for food. Seen in depression, with illness, and as a side effect of some medications.

anorexia nervosa: (AN-uhhl-REE-k-see-ah-nur-VOH-sah) Refusal to maintain body weight over a minimal normal weight for age and height.

antagonist: (AN-tag-on-ist) Medication used to counteract the effects of an opioid (e.g., nalozone).

anteflexion: (AN-tehk-FLEK-shun) The abnormal bending forward of part of an organ.

anteverversion: (AN-tee-VUR-zhon) A tipping forward of an organ as a whole, without bending.
anthrax: (AN-thrax) A disease caused by the spore-forming bacterium Bacillus anthracis that has three clinical forms in humans: inhalational, cutaneous, and gastrointestinal. It can be used as a biological weapon.

antibodies: (AN-tih-baw-dees) An immunoglobulin molecule having a specific amino acid sequence that gives each antibody the ability to adhere to and interact only with the antigen that induced the synthesis.

anticholinesterase: (AN-tih-KOH-lin-ESS-ter-a) A substance that breaks down acetylcholinesterase.

antiuretic: (AN-tih-DYE-yoo-RET-ik) Lessening urine excretion.

antigen: (AN-tih-JEN) A protein marker on the surface of cells that identifies the type of cell.

antitussive: (an-tee-TUS-siv) An agent that prevents or relieves cough.

anuria: (an-YOO-ree-ah) Complete suppression of urine formation by the kidney.

anxiety: (ang-ZYE-uh-tee) The uncomfortable feeling of apprehension or dread that occurs in response to a known or unknown threat.

aphasia: (ah-PAY-zee-ah) Defect or loss of the power of expression by speech, writing, or signs, or of comprehension of spoken or written language, caused by disease or injury of the brain centers, such as stroke syndrome.

aphthous stomatitis: (AF-thus STOH-mah-teez) Small, white, painful areas on the mucous membranes of the mouth that recur.

asperia: (as-PAY-rah) A condition in which growth is stunted.

asthmatic: (uh-STIG-mah-TIZM) An error of refraction in which a ray of light is not sharply focused on the retina but is spread over a more or less diffuse area.

ataxia: (ah-TAY-shee-ah) Failure of muscular coordination; irregularity of muscular action.

atactic: (AT-uh-tihk) Collapsed or airless condition of the lung or portion of lung, caused by obstruction or hyperventilation.

atherosclerosis: (uh-THER-oh-sklor-uh-SIS) A form of arteriosclerosis characterized by accumulation of plaque, blood, and blood products lining the wall of the artery, causing partial or complete blockage of an artery.

augmentation: (AW-men-TAY-shun) The act or process of increasing in size, quantity, degree, or severity.

auscultation: (AW-skul-TAY-shun) Process of listening for sounds within the body, usually sounds of thoracic or abdominal viscera, to detect an abnormality.

autoimmune: (AW-toh-im-YOON) A condition in which the body does not recognize itself and the immune system attacks normal cells.

Ayurvedic: (AY-ur-VEE-dik) An ancient Hindu system of medicine that improves health by harmonizing mind and body.

azotemia: (AY-zoh-TEE-me-ah) An increase in nitrogenous bodies in the blood, especially urea, as measured by the serum blood urea nitrogen (BUN) level.

Bacterium: (BAK-tuh-rh) One-celled organisms that can reproduce but need a host for food and supportive environment. Bacteria can be harmless, normal flora, or disease-producing pathogens.

balanitis: (BAL-uh-neez) Inflammation of the skin covering the glans penis.

behavior management: (BAH-vayr-MAN-ij-ment) Treatment method that uses positive and negative reinforcement to alter behavior.

benign: (bee-NINE) Not progressive; for example, a tumor that is not cancerous.

biofeedback: (BYE-oh-FAH-buk) A form of therapy that uses provision of visual or auditory evidence to a person of the status of an autonomic body.
bronchodilator: (BRONG-koh-DYE-lay-tur) A drug that expands the bronchial tubes by relaxing bronchial smooth muscle.

bronchospasm: (BRONG-koh-spazm) Spasm of the bronchial smooth muscle resulting in narrowing of the airways; associated with asthma and bronchitis.

bruit: (BROO-EE) A humming heard when auscultating a blood vessel that is caused by turbulent blood flow through the vessel.

bulimia nervosa: (buh-LLEE-mee-ah ner-VOH-sah) Recurrent episodes of binge eating and self-induced vomiting.

bulla: (BUH-ah) A large blister or skin lesion filled with fluid. May also occur in lung tissue.

bundle of His: (BUN-duhl of HISS) A bundle of fibers of the impulse-conducting system of the heart. Originates in the atrioventricular (AV) node.

bulgarity: (BULG-ar-ih-TEE-uh) The treatment of disease with medication at which the maximum therapeutic dose will not result in increased relief and may result in undesirable side effects.

cell-mediated immunity: (SELL ME-di-tayd im-YOO-nih-tee) Production of lymphocytes by thymus in response to antigen exposure.

chemotherapy: (KEE-mo-THAY-ruh) A group of diseases that affect the myocardium’s (heart muscle’s) structure or function.

cardiomegaly: (KAR-dee-oh-MEH-gah-lee) Enlargement of the heart.

cardiomyopathy: (KAR-dee-oh-my-AW-pah-fee) A group of diseases that affect the myocardium’s (heart muscle’s) structure or function.

cardioplegia: (KAR-dee-oh-PLEE-je-ah) Arrest of myocardial contraction, as by use of chemical compounds or cold temperatures in cardiac surgery.

cardiopulmonary: (KAR-dee-oh-PUL-moh-nee) Pertaining to both poles. Bipolar terroism.

ceiling effect: (SEE-ing e-FEK) The dose of medication at which the maximum therapeutic effect is achieved. Increasing the dose beyond the therapeutic dose will not result in increased relief and may result in undesirable side effects.

cerebrovascular: (sir-EE-broh-V AS-kul-ayr) Pertaining to the blood vessels of the cerebrum or brain.

chell effect: (SEE-ing e-FEK) The dose of medication at which the maximum therapeutic effect is achieved. Increasing the dose beyond the therapeutic dose will not result in increased relief and may result in undesirable side effects.

cellular: (SELL-yoo-LYE-tiss) Inflammation of cellular or connective tissue.

cystic hygroma: (KIS-tik hy-GOR-mah) A condition marked by involuntary function such as heart rate, blood pressure, or respiratory rate.

biopsy: (BY-awp-see) A sample of tissue removed for examination.

bioterrorism: (BYE-oh-TAYR-uh-RIZ-um) Biological agent use or threat of use with a pathological organism for terrorist purposes.

bipolar: (bye-POH-lur) Having two poles or pertaining to both poles. Bipolar disorder is characterized by episodes of manic and depressive behavior.

blanch: (BLANCH) To lose color. May also occur in lung tissue.

blepharitis: (BLEF-uh-RYE-tiss) Inflammation of the eyelids.

bipolar: (BY-awp-see) A sample of tissue removed for examination.

bradycardia: (KAR-dee-yak OWT-kar-dye-ah) Normal concentration, usually composed of mineral salts, occurring within the body, chiefly in the hollow organs or their passageways. Also called stones, as in kidney stones and gallstones.

cancer: (KAN-sir) A general name for more than 100 diseases in which abnormal cells grow out of control; a malignant tumor.

cannula: (KAN-yoo-lah) A flexible tube that can be inserted into the body guided by a stiff, pointed rod. For example, an intravenous (IV) cannula is guided by a metal needle.

capillary permeability: (KAP-ih-lar-ee PER-me-ah-tee) The ability of substances to diffuse through capillary walls into tissue spaces.

capillary refill: (KAP-ih-lar-ee RE-fill) The amount of time required for color to return to the nailbed after having been compressed, normally 3 seconds or less. Indicator of peripheral circulation.

caput medusae: (KAP-ut mih-DOO-see) Dilated veins around the umbilicus, associated with cirrhosis of the liver.

carbohydrate: (KAR-bun-tur) A nervous system that occurs while medicated with long-acting analgesics. Pain that occurs while medicated with long-acting analgesics. Pain that occurs while medicated with long-acting analgesics.

carotid artery: (KAR-ohh TAY-ruh) A blood vessel that is compressed of the heart by the fluid accumulating in the pericardial sac surrounding the heart.

cardiogenic shock: (KAR-dee-oh-JEN-ick SHAWK) Occurs when the heart muscle is unhealthy and contractility is impaired.

cardiovascular: (sir-EE-broh-V AS-kul-ayr) Pertaining to the blood vessels of the cerebrum or brain.

cellulitis: (SELL-yoo-LYE-tiss) Inflammation of cellular or connective tissue.

cystic hygroma: (KIS-tik hy-GOR-mah) A condition marked by involuntary function such as heart rate, blood pressure, or respiratory rate.
muscular twitching of the limbs or facial muscles.

**chronic illness**: (KRAW-nick ILL-ness) An illness that is long lasting or recurring and usually interferes with a person’s ability to perform activities of daily living. Medical care and hospitalization are often required on an ongoing basis.

circumcise: (SIR-kuhm-size) Surgical removal of the foreskin covering the head of the penis.

cirrhosis: (sih-ROH-siss) Chronic disease of the liver, associated with fat infiltration and development of fibrotic tissue.

civil law: (SI-vil LAW) Provides the rules by which individuals seek to protect their personal and property rights.

claudication: (KLAW-di-KAY-shun) Severe pain in the calf muscle from inadequate blood supply.

clubbing: (KLUB-ing) A condition in which the ends of the fingers and toes appear bulbous and shiny, most often the result of lung disease.

cochlear implant: (KOH-ler-ee-ER IM-plant) A device consisting of a microphone, signal processor, external transmitter, and implanted receiver to aid hearing.

code of ethics: (KOH-de-EYE-icks) A traditional compilation of ideal behaviors of a professional group.

codendence: (KOH-de-PEN-dence) A situation in which the significant others in a family group begin to lose their own sense of identity and purpose and exist solely for the abuser.

cognitive: (KAHG-nih-tiv). The ability to think rationally and to process thoughts.

collic: (KAH-lik) Spasm of the diaphragm. Medical care and hospitalization are often required for therapeutic or diagnostic reasons.

collateral circulation: (SIR-kew-LAW) Provides the rules of blood because of impaired pumping function and sodium and water retention. Congestion refers to the buildup of fluid that ranges from mild to life threatening (pulmonary edema). With right-sided heart failure, the fluid buildup is seen in the lungs and, if severe, immediate treatment is required or death can occur.

collagen: (KOH-lehn) A protein that makes up skin, bones, and cartilage. Medical care and hospitalization are often required for therapeutic or diagnostic reasons.

collarette: (KOH-lay-RET-uh) A small, rounded swelling.

collins: (KOH-ling) The process of converting reaction products to their natural form.

colle: (KAH-leh) A surgical incision of any tissue and usually interferes with a person’s ability to perform activities of daily living. Medical care and hospitalization are often required on an ongoing basis.

comedone: (KOH-me-doh) Skin lesion that occurs in acne vulgaris (closed form: whitehead; open form: blackhead).

commissurotomy: (KOH-mih-shoo-ROH-tuh-MOE) Surgical incision of any commissure as in cardiac valves to increase the size of the orifice.

compulsive: (KOHMP-uhl) A condition in which there is an effort to overcome or work through the stresses of daily life in an effort to overcome or work through them.

cor pulmonale: (KOR PUL-mah-NAH-lee) Hypertrophy or failure of the right ventricle from disorders of the chest wall, lungs, and pulmonary vessels, as with increased pulmonary pressure caused by chronic obstructive pulmonary disease (COPD).

coronary artery disease: (KOR-uh-nah-ree AR-tuh-reh dih-ZEEZ) Narrowing of the coronary arteries sufficient to prevent adequate blood supply to the myocardium.

cranectomy: (KRAY-nee-EYE-koh or KRAY-nee-oh-EYE-koh) Excision of a segment of the skul.

cranial: (KRAY-nee-ahl) Pertaining to the skull.

cull: (KUL-chur) A craking sound such as that heard in the chest with pneumonia or other lung diseases or with grating of the ends of a fractured bone.

crulment: (KOHRL-uh-ment) A persistent, uncomfortable feeling.

cryptorchidism: (KOH-rih-kohh-rid-uh-zuhm) The presence of pathogenic microbes in the body, without development of a symptomatic infection.

colitis: (kuh-LEE-tiss) Inflammation of the colon.

collateral circulation: (kuh-uh-LAW-tur-ul) Small branches off of a main artery that can supply blood to other parts of the body. Medical care and hospitalization are often required for therapeutic or diagnostic reasons.

colostomy: (koh-LAW-stuh-MOE) An artificial opening (stoma) created in the large intestine and brought to the surface of the abdomen for evacuating the bowels.

colporrhaphy: (kohl-POOR-ah fee) Surgical repair of the vagina.

colposcopy: (kul-POS-koh-phee) Examination of the vulva, vagina, and cervix by means of a magnifying lens and a bright light.
Appendix F

Glossary

1403

and ancestry and having an appreciation of and attention to the crafts, arts, music, foods, and clothing of various cultures.

cultural competence: (KUL-chur-uhl KOM-peh-tens) Having an awareness of one’s own culture and not letting it have an undue influence over another person’s culture. Having the knowledge and skills about a culture that are required to provide care.

cultural diversity: (KUL-chur-uhl dih-VER-sih-tee) Representing two or more cultures; the differences among cultures. For example, the United States includes people from many countries.

cultural sensitivity: (KUL-chur-uhl SEN-sih-TIV-ih-tee) Being aware of and sensitive to cultural differences. Avoiding behavior or language that may be offensive to another person’s cultural beliefs.

culture: (KUL-chur) The socially transmitted behavior patterns, beliefs, values, customs, arts, and all other characteristics of people that guide their worldview.

curet: (kyoo-RET) A loop, ring, or spoon-shaped instrument, attached to a handle and having sharp or blunt edges; used to scrape tissue from a surface.

custom: (KUS-tum) A custom is the stance or something that an individual uses to scrape tissue from a surface.

decubitus: (SYE-uh-niss) Slightly depressed area of the skin caused by the pressure of one’s own body weight.

decubitus ulcer: (SYE-uh-niss) A chronic disease characterized by impaired production or use of insulin and high blood glucose levels.

diabetes mellitus: (DYE-uh-REE-ah) Passage of fluid or uniformly colored stools.

diabetic blood pressure: (dye-ah-STAHL-lik BLUHD PREH-shure) The amount of pressure exerted on the wall of the arteries when the ventricles are at rest. The bottom number in a blood pressure reading.

diffusion: (dih-FUND-uhn) The tendency of molecules of a substance (gaseous, liquid, or solid) to move from a region of high concentration to one of lower concentration.

dilation and curettage: (die-LAY-shun and kyoo-er-e-TAHZH) A surgical procedure that expands the cervical canal of the uterus (dilation) so that the surface lining of the uterine wall can be scraped (curettage).

diplopia: (dip-LOH-pee-ah) Double vision.

displacement: (dis-PLAYSS-ment) Transfer of emotion from the original idea with which it was associated to a different idea, allowing the client to avoid acknowledging the original source.

disseminated intravascular coagulation: (dih-SEH-mih-nay-ted IN-trah-VASYOo-koh-lar koh AG-yoo-LAY-shun) A pathological form of coagulation that is diffuse (widespread) rather than localized, as would be the case in normal coagulation. Clotting factors are consumed to such an extent that generalized bleeding may occur.

distributive shock: (dis-TRIB-yoo-ah) Excessive dilation of the veins and arterioles, leading to decreased distribution of blood, resulting in shock.

diverticulitis: (DYE-VER-tik-yoo-oh-LYE-tiss) Inflammation of a diverticulum (a sac or pouch in the walls of a canal or organ, usually the colon), especially inflammation involving diverticula of the colon.

diverticulosis: (DYE-ver-tik-yoo-oh-LOH-siss) The presence of diverticula in the absence of inflammation.

do not resuscitate (DNR): (DOO not res-US-suh-ih-TAYT) An order not to do CPR (cardiopulmonary resuscitation) at the end of life.

dormant: (DOOR-mant) Condition of greatly reduced metabolic activity permitting long-term survival and possible reactivation of bacterial endospores, protozoan cysts, larval stages of worm parasites, and viruses.

Dressler’s syndrome: (DRESS-lers SYNDROHm) Postmyocardial infarction syndrome; pericarditis.

durable power of attorney: (DUR-uh-bull POW-ur uv uh-TUR-nee) Person legally designated to speak for a patient...
when the patient is no longer able to speak for himself or herself.

dysarthria: (dis-AR-three-ab) Imperfect articulation of speech caused by disturbances of muscular control resulting from central or peripheral nervous system damage.

dysfunctional: (DIS-FUNK-shun-uh) Family or work environment that does not function effectively, sometimes because of other problems of members.

dyspareunia: (DIS-puh-ROO-nee-ah) Occurrence of pain in the labia, vagina, or pelvis during or after sexual intercourse.

dysphagia: (dis-FAY-ee-ah) Inability to swallow or difficulty swallowing.

dysplasia: (dis-PLAY-zee-ah) Abnormal development of tissue.

dyspnea: (DISP-nee-ah) Subjective sense of labored breathing that occurs because of insufficient oxygenation.

dysreflexia: (DIS-ree-FLIK-see-ah) State in which an individual with a spinal cord injury at or above T6 experiences an uninhibited sympathetic response to a noxious stimulus.

dysrhythmia: (dis-RITH mee-yah) Abnormal, disordered, or disturbed cardiac rhythm.

dysuria: (dis-YOO-ree-ah) Difficult or painful urination.

eccymoses: (ECK-uh-MOH-siss) A bruise of varying size, the color of which may be blue-black, changing to greenish yellow or yellow with time.

ectasia: (ek-TAY-see-ah) Replacement of normal tissue with fibrous tissue.

ectopic: (ek-TOP-ick) Out of normal position. Example, ectopic hormones are secreted from sites other than the gland where they would normally be found.

edema: (uh-DEE-muh) Collection of excess fluid in body tissues.

ejaculation: (ee-JAK yoo-lee-shun) The release of semen from the male urethra.

electrocardiogram: (ee-LEK-troh-KAR-dee-oh-GRAM) A recording of the electrical activity of the heart.

electrocautery: (ee-LEK-troh-CAW-tur-ee) Cauterization using platinum wires heated to red or white heat by an electric current, either direct or alternating.

electrocoagulated: (ee-LEK-troh-COH-AG-yoo-LAY-ted) Coagulation of tissue by means of a high-frequency electric current.

electroconvulsive therapy (ECT): (ee-LEK-troh-kun-VUL-siv THER-uh-pee) A type of somatic therapy in which an electric current is used to produce convulsions to treat such conditions as depression.

electrolyte: (ee-LEK-troh-lit) A substance that when dissolved in water can conduct electricity.

emboli: (EM-buh-lie) Solid, liquid, or gaseous masses of undissolved matter traveling with the fluid current in a blood or lymphatic vessel.

embolism: (EM-buh-lizm) Foreign substance or blood clot that travels through the circulatory system until it obstructs a vessel.

emphysema: (EM-fih-SEE-mah) Distention of interstitial tissue by gas or air; chronic pulmonary disease marked by terminal bronchiolae and alveolar destruction and air trapping.

empyema: (EM-pye-EE-mah) Pelvis of endometrium of the uterus.

encephalitis: (EN-seff-uh-LEE-tiss) Inflammation of the brain.

endarterectomy: (end-AR-tur-EE-tiss) Excision of thickened atherosclerotic areas of the aorta of the innermost coat of an artery.

endogenous: (en-DOH-jen-us) Produced or originating from within a cell or organism.

endometritis: (EN-doh-meh-TRISS) Inflammation of the endometrium of the uterus.

endorphins: (en-DOR-fins) Naturally occurring opioids in the body, many times increasing the pain threshold.

endoscopy: (EN-doh-scope) An endoscopic examination of the organs or cavity. Can be flexible or rigid.

enteritis: (en-TER-EYE-tiss) Inflammation of the intestines, particularly of the mucusa and submucosa of the small intestine.

enucleation: (en-NEW-klee-AY-shun) Removal of an organ or other mass from its supporting tissues, as of the eyeball from the orbit.

epidemiological: (EPP ih-DEE-ee-ah-LEH-ah-KEE-ee-ah) Study of the distribution and determinants of health-related states and events in populations and the application of this study to the control of health problems.

epididymitis: (EPP ih-DID-ih-MY-tiss) Inflammation or infection of the epididymis.

epidural: (EP ih-DUHR-uh) Situated on or outside the dura mater.

epinephrine: (EPP ih-NEFF-ree) A hormone secreted by the adrenal medulla in response to stimulation of the sympathetic nervous system.

epispadias: (EPP ih-SPAY-dee-uh-ah) A congenital male defect in which the opening of the urethra is on the dorsum of the penis, instead of the tip.

epithelialization: (EPP ih-THEE lee-uh-EE-tiss) The growth of skin over a wound.

equanialgesic: (EE kwheel AN uh-lle-JEE-ick) Drugs having equal pain-killing effect. The same degree of pain relief may require different doses when different medications are given or medications are given by different routes.

cycle dysfunction: (EHP ih REK-til DIS-FUNK shun) Inability to have an erection sufficient for sexual intercourse.

creep: (EPP ih REK shun) Enlargement and hardening of the penis caused by engorgement of blood.

erythema: (EPP ih TEEH-ee-mah) Diffuse redness over the skin.

eschar: (ESS kar) Hard scab or dry crust that results from necrotic tissue.

escharotomy: (ESS kar AWT oh mee) Removal of a slough or scab formed on the skin and underlying tissue of severely burned skin.

esophagastroduodenoscopy: (EHP SOFF ah go GAS troh doo AW den AWW kuh pee) An endoscopic procedure that allows the physician to view the esophagus, stomach, and duodenum.

esophagoscopy: (EHP soff ah GAWS kuh pee) Examination of the esophagus using an endoscope.

esotropia: (ESS oh TROH pee ah) Strabismus in which there is deviation of the visual axis of one eye toward that of the other eye, resulting in diplopia. Also called cross-eyed.

essential hypertension: (EHP ih SEN shul HYE per TEN shun) Chronic elevation of blood pressure resulting from an unknown cause.

ethical: (EETH ih kuhl) Describes behavior guided by a system of moral principles or standards.

ethics: (EETH iks) Branch of philosophy that answers questions about morality such as good, bad or right, wrong.

ethnic: (EETH ick) Pertaining to a religious, racial, national, or cultural group. For example, individuals may identify with the Jewish, Catholic, or Islamic religions.

ethnocentrism: (ETH ih noll SEN trizm) The tendency to think that one's own ways of thinking, believing, and acting are the only right ways. People who are

Control and Prevention or an alcohol-based hand sanitizer solution.

**Health** (HEALTH) A condition in which all functions of the body and mind are normally active.

**Hearing aid** (HEER-ing AYD) An instrument to amplify sounds for those with hearing loss.

**Heatstroke** (HEET-strohk) An acute and dangerous reaction to heat exposure, characterized by high body temperature, usually higher than 105°F (40.5°C).

**Helicobacter pylori** (HEET-strohk) An acute and dangerous reaction to heat exposure, characterized by high body temperature, usually higher than 105°F (40.5°C).

**Hepatitis** (HEE-moh-THAW-raks) Inflammation of the liver, most often viral.

**Hemoptysis** (hee-MOP-tih-siss) Coughing Blood in the pleural space; may be associated with trauma, tuberculosis, or pneumonia.

**Hemophilia** (HEE-moh-fil-ee-ah) A hereditary blood disease marked by greatly prolonged coagulation time, with consequent failure of the blood to clot and abnormal bleeding.

**Hernia** (HER-ne-uh) Hernia (HER-ne-uh) Hernia (HER-ne-uh) Herniation of the liver.

**Hepatomegaly** (hep-oh-tuh-MEG-ah-lee) Enlargement of the liver and spleen.

**Hernia** (HER-ne-uh) Hernia (HER-ne-uh) Hernia (HER-ne-uh) Herniation of the liver.

**Hepatitis** (HEE-moh-THAW-raks) Inflammation of the liver, most often viral.

**Hepatomegaly** (hep-oh-tuh-MEG-ah-lee) Enlargement of the liver.

**Hepatorenal syndrome** (hep-PAT-oh-REE-nuhh SIR-drohm) A deadly kidney failure that sometimes accompanies liver disease.

**Hepatitis** (HEE-moh-THAW-raks) Inflammation of the liver, most often viral.

**Hemoptysis** (hee-MOP-tih-siss) Coughing Blood in the pleural space; may be associated with trauma, tuberculosis, or pneumonia.

**Hemorrhaging** (heem-ee-pee-ahng) A condition in which an organ or a part of an organ through the wall of the cavity that normally contains it.

**Herpetic** (her-PEH-ick) Pertaining to herpes.

**Hialtal hernia** (high-ay-uhl HER-nee-ah) A condition in which part of the stomach protrudes through and above the diaphragm.

**High-density lipoprotein** (HDL): (HYE-den-sih-tee LIP-oh-proh-teen) Plasma lipids bound to albumin consisting of lipoproteins. It has been found that those with high levels of HDL have less chance of having coronary artery disease.

**Histamine** (hih-STAH-mean) A substance produced in the body that increases gastric secretion, increases capillary permeability, and contracts the bronchial smooth muscle. Plays a role in allergic reaction.

**Holistic** (hole-ih-stik) The view that “like cures like” and uses tiny doses of a substance that create the symptoms of disease.

**Homeopathy** (HOH-mee-oh-pa-thee) System of medicine based on the theory that “like cures like” and uses tiny doses of a substance that create the symptoms of disease.

**Homeostasis** (HOH-mee-oh-stay-siss) Maintaining a constant balance, especially whenever a change occurs.

**Hopelessness** (HOH-mee-oh-STAY-siss) Limited or unavailable alternatives; lacking energy.

**Hormans’ sign** (HOH-manz SIGHN) An assessment for venous thrombosis in which calf pain with dorsiflexion occurs if thrombosis is present.

**Hyperventilation** (HIYE-per-voh-LEE-ah) A condition caused by enlargement of the liver.

**Hydrocephalus** (HYE-droh-SEF-uh-uhluh) A condition caused by enlargement of the cranium caused by abnormal accumulation of cerebrospinal fluid within the cerebral ventricular system.

**Hydrodynamic** (HYE-droh-NEE-drom) Normal dilution of kidneys caused by obstruction of urine flow.

**Hydrostatic** (HYE-droh-STAT-ik) Pertaining to the pressure of liquids in equilibrium and to the pressure exerted by liquids.

**Hypercalcemia** (HYE-per-kahl-SEE-mee-ah) An excessive amount of calcium in the blood.

**Hyperglycemia** (HYE-per-glye-SEE-mee-ah) Excess glucose in the blood.

**Hyperkalemia** (HYE-per-kahl-LEE-mee-ah) An excessive amount of potassium in the blood.

**Hyperlipidemia** (HYE-per-lih-PIEEE-dee-ah) Excessive quantity of fat in the blood.

**Hypermagnesemia** (HYE-per-MAG-nuh-ZEE-mee-ah) Excess magnesium in the blood.

**Hypernatremia** (HYE-per-nuh-TRREE-mee-ah) Excess sodium in the blood.

**Hyperperosia** (HYE-per-oh-pee-ah) Farsightedness.

**Hyperplasia** (HYE-per-play-zee-ah) Excessive increase in the number of normal cells.

**Hypertension** (HYE-per-TEN-shun) Abnormally elevated blood pressure.

**Hypertensive emergency** (HYE-per-TEN-siv) Systolic blood pressure above 180 mm Hg and diastolic blood pressure above 120 to 130 mm Hg.

**Hypertonic** (HYE-pur-TRUN-ik) Exerts greater osmotic pressure than blood.

**Hypertrophy** (HYE-per-truh-fee) An increase in the size of an organ or structure, or of the body, owing to growth rather than tumor formation.

**Hypuricemia** (HYE-per-yoo-ah-ah-SEE-mee-ah) An excess of uric acid or urates in the blood.

**Hyperventilation** (HYE-per-VEN-tih-LAY-shun) Increased ventilation that results in a lowered carbon dioxide (CO₂) level (hypocapnia).

**Hypervolemia** (HYE-per-voh-LEE-mee-ah) An abnormal increase in the volume of circulating blood.

**Hypocalcemia** (HYE-per-kahl-SEE-mee-ah) Reduced amount of calcium in the blood.

**Hypoglycemia** (HYE-per-glye-SEE-mee-ah) Below-normal amount of glucose in the blood.

**Hypokalemia** (HYE-per-kahl-LEE-mee-ah) Reduced amount of potassium in the blood.

**Hypomagnesemia** (HYE-per-MAG-nuh-ZEE-mee-ah) Reduced amount of magnesium in the blood.
hysterotomy: (HISS-tuh-RAW-tuh-mee) Surgical removal of the uterus through the abdominal wall or vagina.
hysteroscopy: (HISS-tuh-RECK-tuh-suh) Diminution of the blood vessels.
hypoxia: (HYE-poh-voh) Reduced amount of oxygen to the body tissues.
hypovolemic shock: (HYE-poh-voh-LEEM-ick) Low volume of blood in the circulatory system.
hypovolemic: (HYE-poh-voh-LEEM-ick) Low volume of blood in the circulatory system.
hypothroidism: (HYE-poh-THUR-mee-ah) Body temperature below 95°F (35°C).
hypothermia: (HYE-poh-TAWN-ik) Pertaining to defective muscular tone or tension; having a lower concentration of solute than intracellular or extracellular fluid.
hypotonia: (HYE-poh-TAW-nee) Downward deviation of the eye away from the visual axis.
hypovolemia: (HYE-poh-voh-LEE-mee-ah) The most common form of dehydration resulting from the loss of fluid from the body; results in decreased blood volume.
hypovolemic: (HYE-poh-voh-LEEM-ick) Low volume of blood in the circulatory system.
hypovolemic shock: (HYE-poh-voh-LEEM-ick SHAWK) Shock that occurs when blood or plasma is lost in such quantities that the remaining blood cannot fill the circulatory system despite constriction of the blood vessels.
hypoxemia: (HYE-pock-SEE-mee-ah) Deficient oxygenation of the blood.
hypoxia: (bye-POCK-see-ah) Diminished availability of oxygen to the body tissues.
hysterectomy: (HISS-tuh-RECK-tuh-mee) Surgical removal of the uterus through the abdominal wall or vagina.
hysterosalpingogram: (HISS-tur-oh-SAL-pinj-oh-gram) Radiograph of the uterus and fallopian tubes.
hysteroscopy: (HISS-tur-AWS-koh-pee) Endoscopic direct visual examination of the canal of the uterine cervix and the cavity of the uterus.
hysterotomy: (HISS-tuh-RAW-tuh-mee) Incision of the uterus.

**international normalized ratio:** (IN-ter-nASH-ul NOR-muh-lized RAY-she-oh) The World Health Organization’s standard for reporting the prothrombin time assay test when the thromboplastin reagent developed by the first International Reference Preparation is used. The reagent was developed to prevent variability in prothrombin time testing results and provide uniformity in monitoring therapeutic levels for coagulation during oral anticoagulation therapy.

**interstitial:** (IN-ter-STISH-ul) Fluid between tissues.

**intervention:** (IN-ter-VEN-shun) One or more actions taken in order to modify an effect.

**intracellular:** (IN-trah-SELL-yoo-ler) Fluids located within the blood cell.

**intracranial:** (IN-trah-KRAY-nee-uh) Within the cranium or skull.

**intraoperative:** (IN-trah-AP-er-uh-tiv) Occurring during a surgical procedure.

**intravascular:** (IN-trah-VAS-koo-lar) Fluids located within the blood vessels.

**intravenous:** (IN-trah-VEE-nus) Within or into a vein.

**intrinsinc factors:** (in-TRIN-sik FAK-ters) Internal variables.

**intrusssuction:** (IN-tuh-suh-SEP-shun) Shaping of one part of an intestine into another adjacent to it.

**ipsilateral:** (IP-sih-LAT-ur-uhl) On the same side; affecting the same side of the body.

**ischemia:** (iss-KEY-me-ah) Condition of inadequate blood supply.

**isoelectric line:** (EYE-so-ee-LEK-trick LINE) The period when the electrical tracing is at zero and is neither positive nor negative.

**isolated systolic hypertension:** (EYE-suh-lay-ted siss-TAW-lik) The systolic pressure is 160 mm Hg or more, but the diastolic pressure is less than 95 mm Hg.

**isotonic:** (EYE-so-TAW-nik) A fluid that has the same osmolarity as the blood.

**jaundice:** (JAWN-diss) Yellowing of the skin and the sclera of the eye.

**joint:** (JOYNT) An articulation. The point of juncture between two bones.

**Kaposi’s sarcoma:** (kay-POH-sees sar-ko-mah) A vascular malignancy that is often first apparent in the skin or mucous membranes but may involve the viscera.

**ketoacidosis:** (KEE-tuh-as-ih-DOH-siss) A condition in which fat breakdown produces ketones, which cause an acidic state in the body; may be associated with weight loss or diabetes mellitus.

**Kussmaul’s respirations:** (KOOS-mahlz RES-pih-RAY-shuns) Term describing deep respirations of an individual with ketoacidosis.
laceration: (la-sir-A-shun) A wound or irregular tear of the flesh.
lactic acid: (LAK-tik AS-id) By-product of anaerobic metabolism.
laminectomy: (LAM-ih-NEK-toh-mee) The excision of a vertebral posterior arch, usually to remove a lesion or herniated disk.
laparoscopy: (LAP-uh-raw-SKOP-ee) Exploration of the abdomen with an endoscope.
laparotomy: (LAP-uh-RAW-tuh-mee) The surgical opening of the abdomen; an abdominal operation.
laryngeal edema: (lah-REHN-jee-uhl YEH-di-EM-uh) Sudden swelling of the larynx occurring with severe allergic reactions.
laryngitis: (lar-in-JYE-tiss) Inflammation of the larynx.
laser ablation: (LAY-zer uh-BLAY-shun) Therapeutic destruction of a growth or part of a growth by laser treatment.
lavage: (lah-VAZH) Washing out of a cavity.
law: (LAW) The further formalization of moral considerations.
leadership: (LEE-der-ship) The process of socially influencing others to obtain their assistance and support to accomplish a common task.
leiomyoma: (LYE-uh-MY-uh-MA) A myoma consisting principally of smooth muscle tissue.
leukemia: (loo-KEE-mee-ah) A malignancy of the blood-forming cells in the bone marrow.
leukocytosis: (LOO-koh-sye-TOH-siss) An increase in the number of leukocytes in the blood, generally caused by the presence of infection and usually transient.
leukopenia: (LOO-koh-pee-nee-yah) Abnormal decrease of white blood cells, usually below 5000/mm³.
limitation of liability: (lim-ih-TAY-shun OF LYE-uh-uhl-BIL-toh-mee) The level of responsibility that society places on individuals for their actions.
libido: (lib-BOO-doh) Sexual drive, conscious or unconscious.
lichenified: (lye-KEN-ih-fyed) Thickened or hardened from continued irritation.
limitation of liability: (lim-ih-TAY-shun OF LYE-uh-uhl-BIL-toh-mee) Steps that health care professionals can take to limit their liability.
living will: (LY-ing WIL) A document instructing health care workers about a patient’s preferences when he or she is no longer able to communicate. Implementation of living wills varies by state.
lobectomy: (loh-BEK-tuh-mee) Surgical removal of a lobe of any organ or gland.
low-density lipoprotein (LDL): (LOH DEN-sih-tee LIH-pohh-PROH-teen) A lipoprotein that transports cholesterol and triglycerides from the liver to peripheral tissues. LDL allows fats and cholesterol to move within the water-based solution of the blood. Increased LDL cholesterol is associated with cardiovascular disease, so it is often referred to as “bad cholesterol.”
lower gastrointestinal (lower GI) series: (LOH-er GAL-soh-troh-inh-ESS-teh-nih-nahl SEER-eez) The use of barium sulfate as an enema to facilitate x-ray and fluoroscopic examination of the colon.
lymphadenopathy: (lim-FAD-eh-NAH-puh-thee) Any disorder of the lymph nodes.
lymphangiitis: (lim-FAN-jee-uh-TISS) Inflammation of lymphatic channels or vessels.
lymphedema: (LIMPF-uh-DEE-mah) An abnormal accumulation of tissue fluid (potential lymph) in the interstitial space.
lymphocytes: (LIM-foh-sites) Cells present in the blood and lymphatic tissue that provide the main means of immunity for the body; white blood cells.
lymphoma: (lim-FOH-mah) A usually malignant lymphoid neoplasm.
maceration: (MAH-ruh-SHUN) Process of raising the edges of the abdominal wound and eliminating serous drainage with an endoscope.
malignant: (MAH-lih-NUNT) Growing, of anaerobic metabolism.
malignancy: (MAH-lih-NAN-see-nee) Process of raising the borders of an evacuated tumor sac to the edges of the abdominal wound and stitching them there to form a pouch.
mastalgia: (mass-TAL-jee-uh) Pain in the breast.
mastectomy: (mass-TEHK-tuh-mee) Excision of the breast.
mastitis: (mass-TYE-tiss) Inflammation of the breast.
mastopexy: (MAS-toh-PEKS-ee) Correction of a pendulous breast by surgical fixation and plastic surgery.
mastitis: (mass-TYE-tiss) Inflammation of the breast.
mastitis: (mass-TYE-tiss) Inflammation of the breast.
mastopexy: (MAS-toh-PEKS-ee) Correction of a pendulous breast by surgical fixation and plastic surgery.
mastectomy: (mass-TEHK-tuh-mee) Excision of the breast.
mastitis: (mass-TYE-tiss) Inflammation of the breast.
mastopexy: (MAS-toh-PEKS-ee) Correction of a pendulous breast by surgical fixation and plastic surgery.
mediastinum: (MEE-dee-uh-STY-een-uh) A septum or cavity between two principal portions of an organ.
megacolon: (MEG-uh-KOH-leen) Extremely dilated colon.
melena: (muh-LEE-nah) Black, tarry feces caused by action of intestinal secretions on free blood.
menarche: (meh-NAR-kee) The initial menstrual period, normally occurring between the ninth and 17th year.
Menière’s disease: (meh-NEE-rehz di-ZEEZ) A recurrent and usually progressive group of symptoms including progressive deafness, ringing in the ears, dizziness, and a sensation of fullness or pressure in the ears.
meningitis: (men-in-JYE-tiss) Inflammation of the membranes of the spinal cord and brain.
menopause: (MEN-oh-pawz) The period that marks the permanent cessation of menstrual activity, usually occurring between the ages of 35 and 58.
mental health: (MEN-tuh HELTH) State of being adjusted to life; able to be flexible, successful, maintain close relationships, solve problems, make appropriate judgments, and cope with daily stresses.
mortality: (more-BID-uh-tee) State of being diseased.
morality: (muh-RAL-uh-tee) A social barometer that dictates what is good or bad in a society.
morbid: (muh-BID-ih-tee) State of being diseased.
mortality: (more-TAL-ih-tee) Condition of being mortal; number of deaths in a population.
mucolytic: (MIK-ear-awt-kik) Agent that liquefies sputum.
mucopurulent cervicitis: (MIK-ear-awt-kuh-PYE-ooh-uhl hil-uh-SIR-vih-SYE-tiss) Inflammation of the cervix producing mucus and purulent discharge.
mucosis: (MI-KOSS-iss) Inflammation of a mucous membrane.
orientation: (OR-ce-en-TAY-shun) The ability to comprehend and to adjust oneself in an environment with regard to time, location, and identity of persons.

orthopnea: (or-THOP-knee-uh) Laboring breathing that occurs when lying flat; relieved when sitting up; associated with left ventricular heart failure.

osmolality: (ahs-moh-LAL-ih-tee) Osmotic concentration; ionic concentration of the dissolved substances per unit of solvent.

osmosis: (ahs-MOH-siss) The passage of solvent through a semipermeable membrane that separates solutions of different concentrations.

osteomyelitis: (AHSH-tee-oh-my-LEYE-tiss) Inflammation of bone, especially the marrow, caused by a pathogenic organism.

osteopathy: (AHSH-tee-oh-AY-puh-thee) A condition characterized by chronic, progressive deafness, especially for low tones.

osteosarcoma: (AHSH-tee-oh-sah-koh-mah) A malignant sarcoma of a bone.

ostorhrea: (OH-toh-REE-uh) Inflammation of the ear with purulent discharge.

otosclerosis: (OH-toh-REE-uh-TECK-seh) A condition characterized by chronic, progressive deafness, especially for low tones.

palpation: (pal-PAY-shun) Use of the fingers or hands to feel something.

pain: (PAYN) An unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage.

paresthesia: (puh-REE-siss) Weakness; incomplete paralysis.

parenteral: (pah-REN-tur-ul) A medication delivery route that is “beside” rather than in the intestine, such as intramuscular, intravenous (IV), or subcutaneous.

paraplegia: (par-ah-PLEE-ja) Paralysis of the lower body, including both legs, resulting from a spinal cord lesion.

paraphimosis: (PAR-uh-fye-MOH-siss) Uncircumcised foreskin that has swollen and stuck behind the head of the penis.

paraplegia: (par-ah-PLEE-ja) Paralysis of the lower body, including both legs, resulting from a spinal cord lesion.

paralysis: (par-ah-LAY-siss) A decreased or complete loss of function of any part or function of the body.

paralysis: (PAR-ah-LAY-siss) A decreased or complete loss of function of any part or function of the body.

paralysis: (PAR-ah-LAY-siss) A decreased or complete loss of function of any part or function of the body.

paralysis: (PAR-ah-LAY-siss) A decreased or complete loss of function of any part or function of the body.

paralysis: (PAR-ah-LAY-siss) A decreased or complete loss of function of any part or function of the body.

pemphigus: (PEM-fih-gus) Acute or chronic serious skin disease characterized by the appearance of bullae (blisters) of various sizes on normal skin and mucous membranes.

penumbra: (puh-NUM-bra) An area of brain tissue surrounding damage from a stroke that may be revived if the brain is reperfused quickly.

pericardial effusion: (PER-ih-kahr-dee-uhl ee-FYOO-zhun) A buildup of fluid in the pericardial space.

pericardial friction rub: (PER-ih-kahr-dee-uhl FRICK-shun RUB) Friction sound heard over the fourth left intercostal space near the sternum; a classic sign of pericarditis.

pericardial tamponade: (PER-ih-kahr-dee-uhl TAM-pon-AID) Compression of the heart by an abnormal filling of the pericardial sac with blood.

pericardioentesis: (PER-ih-kahr-dee-uhl ee-SEN-tiss) Surgical perforation of the pericardium.

pericardiectomy: (PER-ih-kahr-dee-uhl AH-hah-mee) Incision of the pericardium.

pericarditis: (PER-ih-kahr-DYE-tiss) Inflammation of the pericardium.

perimenopause: (PER-ih-may-oh-PAWSS-uhhl) The phase before the onset of menopause, during which the cycle of a woman with regular menses changes, perhaps abruptly, to a pattern of irregular cycles and increased periods of amenorrhea.

perinatal: (PER-ih-nay-TAY-shun) Concerning the period beginning after the 28th week of pregnancy and ending 28 days after birth.

perineal: (PER-ih-nay-TAY-shun) Concerning the period beginning after the 28th week of pregnancy and ending 28 days after birth.

peripheral arterial disease: (PER-ih-PHE-rih-ahl AR-reh-TER-ih-uhl di-ZEEZ) Disease of the peripheral arteries that interferes with adequate flow of blood.
peripheral parenteral nutrition: (puh-RIF-uh-ruhl pah-REN-ter-ruhl new-TRISH-un) Nutrition by peripheral IV injection.

peripheral vascular resistance: (puh-RIF-uh-ruhl VAS-kyoo-lar ree-ZISS-tense) Opposition to blood flow through the vessels.

peristalsis: (par-is-TALL-siss) Progressive, wavelike movement that occurs involuntarily in hollow tubes of the body such as the alimentary (digestive) canal; causes contents of tube to be moved onward.

peristomal: (PER-ih-STOH-muhl) Area around a stoma.

peritoneal dialysis: (PER-ih-toh-NEE-uhl dye-AL-ih-siss) The employment of the peritoneum surrounding the abdominal cavity as a dialyzing membrane for the purpose of removing waste products or toxins accumulated as a result of renal failure.

peritonitis: (PEAR-ih-toh-NYE-tiss) Inflammation of the peritoneum.

personal protective equipment: (PUR-sun-al proh-TEK-tiv ih-KWIIP-man) Items worn to protect oneself and one’s patients from direct transmission of organisms that includes gloves, surgical masks, goggles, gowns, and shoe booties based on the task to be performed and the type of isolation precautions in use.

petechiae: (pek-TEE-kee-eye, puh-TEEK-ee-eye) Small, purplish, hemorrhagic spots on the skin that appear in certain illnesses and bleeding disorders.

phagocytosis: (fyay-soh-TOH-siss) Ingestion and digestion of bacteria and particles by phagocytes, cells that have the ability to ingest and destroy particulate substances such as bacteria, protozoa, and cell debris.

pharyngitis: (fair-in-JIGH-tiss) Inflammation of the mucous membranes and lymph tissues of the pharynx, usually acquired by infection.

pseudopseudochromatoma: (FEE-oh-KROH-moh-sigh-TOH-mahl) Rare tumor of the adrenal system that secretes catecholamines.

phimosis: (figh-MOH-siss) Uncircumcised foreskin that cannot be moved down from the head of the penis.

phlebitis: (fla-BYE-tiss) Inflammation of a vein; may be due to irritating intravenous fluids or thrombosis.

phlebotomy: (fleh-BAW-tuh-mee) Entry into a vein for the removal or withdrawal of blood.

phobia: (FOH-bee-uh) A persistent, irrational, intense fear of a specific object, activity, or situation.

photophobia: (FOH-toh-FOH-bee-uh) Abnormal visual intolerance to light.

physical dependence: (FIZ-ik-uh-DEEP-uhn-dens) A pharmacological phenomenon characterized by signs and symptoms of withdrawal when medication is withdrawn.

phytoestrogens: (FYE-toh-ESS-troh-jens) Naturally occurring plant sterols that have an estrogen-like effect.

pinocytosis: (PYE-noh-TEEK-siss) Reabsorption of small proteins from renal filtrate by attachment to the membranes of the tubule cells and then engulfment and digestion.

plaque: (PLAY-o) A severe fibrillar illness caused by the Gram-negative cocco-bacillus Yersinia pestis that is usually transmitted by the bite of an infectious flea. It can also be used as a biological weapon in which primary pneumonic plague would likely occur.

plaque: (PLAK) A deposit of fatty material on the lining of an artery.

plasmapheresis: (PLAS-mahl-er-EES-siss) Removal of blood to separate cells from plasma.

pleuritis: (PLOO-roh-DEE-siss) Creation of adhesions between the parietal and visceral pleura to treat recurrent pneumothorax.

Pneumocystis carinii pneumonia: (new-moh-SIS-tiss cah-RIN-ee-new-MOH-ahy) An acute pneumonia caused by Pneumocystis carinii, a fungus. It occurs in immunodeficient adults and is a defining opportunistic infection of AIDS.

pneumonecetomy: (NEW-moh-NEK-tuh-mee) Surgical removal of all or part of a lung.

pneumothorax: (NEW-moh-THORE-uhks) Air in the pleural space.

poliklothermy: (POY-kih-loh-THUR-ee) Erection that develops because of prolonged pressure on the vessels.

point of maximal impulse: (POYNT of MAKS-ih-muhl IM-puls) The area of the chest where the greatest force can be felt with the palm of the hand when the heart contracts or beats. Usually at the fourth to fifth intercostal space in the midclavicular line.

polycythemia: (PAW-leh-sye-THEE-mee-ah) Excessive red cells in the blood.

polydipsia: (PAW-leh-DIP-sea-uh) Excessive thirst.

polynephropathy: (PAW-leh-new-RAW-puh-see-uh) A disease involving multiple nerves.

polyphagia: (PAW-leh-FAY-jee-ah) Excessive eating.

polyuria: (PAW-leh-YOO-er-ee-ah) Excessive urination.

portal hypertension: (POH-st-AP-er-uh-tiv) Persistent blood pressure elevation in the portal circulation of the abdomen.

postcoital: (pohst-uk-uh-TUL) Occurring after a sexual intercourse.

postmortem care: (pohst-MOR-tum KARE) Care after death.

postoperative: (pohst-AWP-er-uh-tiv) Following a surgical operation.

postpartum: (POHST-AP-er-uh-tiv) After a meal.

powerlessness: (POW-er-less-ness) Perceived lack of control over a situation.

preload: (PREE-lodd) End-diastolic stretch of cardiac muscle fibers; equals end-diastolic volume.

preoperative: (pre-AWP-er-uh-tiv) Preceding an operation.

preprandial: (PREE-PRAN-dee-uh) Before a meal.

prescysis: (PRESS-uh-KYOU-siss) Progressive, bilaterally symmetrical perceptive hearing loss occurring with age; usually occurs after age 50 and is caused by structural changes in the organs of hearing.

presbyopia: (PREZ-by-oh-pee-uh) Diminution of accommodation of the lens of the eye occurring normally with aging, and usually resulting in hyperopia, or farsightedness.

pressure ulcer: (PRESS-sure ULL-sir) An open sore or lesion of the skin that develops because of prolonged pressure against an area.

priapism: (PRY-uh-pizm) Erection that lasts too long.

primary hypertension: (PRY-mare-ee-eye HYE-per-TEN-shun) Abnormally elevated blood pressure of unknown cause. Also called essential hypertension.

probiotics: (proh-bye-AWT-iks) Supplements of live bacteria or yeast that assist the body’s naturally occurring gut microbiota. Often recommended after antibiotic therapy to reestablish the normal microbiota.

proctitis: (prock-TEE-tiss) Inflammation of the rectum and anus.

proctome: (PROH-DOH-mahl) A symptom indicating the onset of a disease.

prostaglandins: (PRAHS-uh-TGLAN-inds) Chemical neurotransmitters usually associated with pain at the site of an injury, periphery.

prostatitis: (PRAWS-tuh-TYE-tiss) Inflammation or infection of the prostate gland.

protozoa: (proh-tow-ZOH-ah) Single-celled parasitic organisms that can move and live mainly in the soil.

pruritus: (proh-RYEE-tiss) Severe itching.

pseudoaddiction: (soo-doh-ad-DIK-shun) Syndrome in which behaviors similar to addiction appear as a result
of inadequate pain control and patients fear not receiving adequate pain medications and pain relief.

Psoriasis: (suh-RYE-ah-siss) Chronic inflammatory skin disorder in which epidermal cells proliferate abnormally fast.

Psychoanalysis: (SYE-koh-uh-NAL-ih-siss) Form of therapy based on the theories of Sigmund Freud, regarding the dynamics of the unconscious.

Psychogenic: (SYE-koh-JEN-ick) Of mental origin.

Psychological dependence: (SYE-koh-LAW-ick-al-dee-PEN-dens) Obsession of obtaining drugs for use other than medicinal; addiction.

Psychosomatic: (SYE-koh-soh-MAT-ik) Having bodily symptoms of psychological, emotional, or mental origin; illness traceable to an emotional cause.

Ptosis: (TOH-siss) Drooping of eyelid.

Puerperal: (poo-oh-ER-per-uhhl) Concerning the puerperium, or period of 42 days after childbirth.

Pulmonary edema: (PULL-muh-NAIR-ee uh-DEE-muh) Acute heart failure in which there is severe fluid congestion in the alveoli of the lungs; life threatening.

Pulse deficit: (PULS DEF-ih-sit) A condition in which the number of pulse beats counted at the radial artery is less than those counted in the same period of time at the apical heart rate.

Purpura: (PUR-pur-uh) Hemorrhage into the skin, mucus membranes, internal organs, and other tissues.

Purulent: (PUR-uh-LENT) Fluid that contains pus.

Pyelogram: (PIE-eh-loh-GRAM) A diagnostic procedure involving x-ray of the kidneys; may be done after injection of a dye into the bloodstream or directly into the kidneys.

Pyelonephritis: (PIE-eh-loh-NAY-pees) Inflammation of the kidney and renal pelvis.

Pyoderma: (PYE-oh-DER-ma) Any acute, inflammatory, purulent bacterial dermatitis.

QSEN project: Quality and Safety Education for Nurses project; focuses on nursing education that promotes the continual improvement of quality and safety in patient care.

Quadriaparesis: (kwah-dihr-par-EE-siss) Weakness involving all four limbs caused by spinal cord injury.

Quadriplegia: (KWAH-dihr-PLEE-jah) Paralysis of all four limbs caused by spinal cord injury.

Range of motion (ROM): (RANJE of MOH-shun) The range of movement of a body joint.

Raynaud’s disease: (rah-NOHZ di-ZEE-ZEE) A primary or idiopathic vasospastic disorder characterized by bilateral and symmetrical pallor and cyanosis of the fingers.

Reality orientation: (ree-AL-ih-tee OR-ee-en-TAY-shun) A process to orient a person to facts such as names, dates, and time, through the use of verbal and nonverbal repeating messages.

Rectoceles: (RECK-oh-see-uh-lees) Protrusion or herniation of the posterior vaginal wall with the anterior wall of the rectum through the vagina.

Red blood cells: (RECK-toh-seel) Protrusion or herniation of the posterior vaginal wall with the anterior wall of the rectum through the vagina.

Raynaud’s phenomenon: (RAY-dee-AY-shun THER-uh-pee) The study of the action of drugs on psychological functions and mental states.

Rhinitis: (rye-NIGH-tiss) Inflammation of the nasal mucosa, usually associated with congestion, itching, sneezing, and nasal discharge.

Rickettsia: (rih-KET-see-uh) A genus of bacteria of the tribe Rickettsiae that multiply only in host cells.

Rinne test: (RIN-neh TEST) A test of hearing made with tuned forks.

Romberg’s test: (RAHM-bergs TEST) A test to determine if a person has the ability to maintain body balance when the eyes are shut and the feet are close together.

Roux-en-Y: (roo-uh-EN-ee) Gastric bypass surgery. A small stomach pouch the size of a thumb is created with staples, then a Y-shaped section of the small intestine is attached to the pouch to allow food to bypass the lower stomach and duodenum.

Rule of nines: (ROOL of NYNES) A formula for estimating percentage of body surface area, particularly helpful in judging the percentage of skin that has been burned.

Sacral radiculopathy: (SAY-krul rad-reek-ah-TEYE-uh) Cancer treatment with ionizing radiation.

Salpingectomy: (SAHL-ping-suh-tee-uh) Cancer treatment with ionizing radiation.

Salpingoscopy: (SAHL-ping-AWS-kee) Endoscopic visualization of the fallopian tubes.

Scleroderma: (SKLE-uh-dair-ma) A chronic manifestation of progressive systemic sclerosis in which the skin is taut, firm, and edematous, limiting movement.

Sclerosis: (skleh-ROH-siss) A hardening or induration of an organ or tissue, especially from excessive growth of fibrous tissue.

Seborrhea: (SEB-uh-REE-uh) Disease of the sebaceous glands marked by increase
sensory overload: (SEN-suh-ree)

sensory deprivation: (SEN-soh-ree-NEW-ruhl)

sensorineural: (SEM-ee-PER-mee-uh-)

semipermeable: (buhl) Partly permeable; said of a membrane that will allow fluids but not the dissolved substance to pass through it.

sensory deprivation: (SEN-suhs-ree-NEW-ruhl) Hearing loss caused by impairment of a sensory nerve.

sensory overload: (SEN-suhs-ree-OH-ver-lod) Excessive stimulation of the senses that creates the potential for maladaptive coping.

sepsis: (SEP-siss) Systemic infection caused by microorganisms in the bloodstream.

serology: (SEAR-oh-luh) Study of substances present in blood serum.

serosanguineous: (SEAR-oh-SANG-gwin-ee-uss) Fluid consisting of serum and blood.

serotonin: (SARE-uh-TOH-nin) A chemical neurotransmitter important in sleep/wake cycles. Reduced serotonin levels are associated with depression.

shock: (SHAWK) A clinical syndrome in which the peripheral blood flow is inadequate to return sufficient blood to the heart for normal function, particularly transport of oxygen to all organs and tissues.

sinusoidal node: (SYE-oh-AY-tree-al) Node at the junction of the superior vena cava and right atrium, regarded as the starting point of the heartbeat.

sinusitis: (SINE-u-SYE-tiss) Inflammation of the sinuses; may be due to viral or bacterial infection, or to allergies.

smallpox: (SMALL-pox) A disease caused by variola virus, an orthopoxvirus. Smallpox was declared eradicated in 1980, but it is still used as a biological weapon.

spleenectomy: (spleh-NEK-tuh-mee) Excision of the spleen.

splenomegaly: (SPLEE-noh-MEG-ah-lee) Enlargement of the spleen.

standard of best interest: (STAN-derd OF BEST IN-trest) A type of decision made about patients’ health care when they are unable to make an informed decision about their own care.

standard precautions: (STAN-derd-pre-KAW-shuns) Guidelines recommended by the Centers for Disease Control and Prevention to reduce the risk of the spread of infection.

stapedectomy: (stay-peh-DEK-tuh-mee) Excision of the stapes to improve hearing, especially in cases of otosclerosis.

staphylococcus: (STAFF-il-uh-KOK-us) A genus of Gram-positive bacteria, which are the most common cause of localized suppurring infections.

status asthmaticus: (STAT-us az-MAT-ih-kus) Prolonged period of unrelieved asthma symptoms.

steatorrhea: (STEE-ah-toh-REE-uh) Fat in the stools; may be associated with pancreatic disease.

stenosis: (steh-NOH-siss) The constriction or narrowing of a passage or orifice, such as a cardiac valve.

stenosis: (steh-NOH-siss) The constriction or narrowing of a passage or orifice, such as a cardiac valve.

stent: (STENT) Any mold or device used to hold tissue in place or to provide support, graft, or Anastomosis while healing is taking place.

sterotype: (STER-ee-oh-TIGHP) An opinion or belief about an individual or group that may not be true.

sterotomy: (stir-NAW-tuh-mee) The operation of cutting through the sternum.

stoma: (STOH-mah) A mouth, small opening, or pore.

stomatitis: (STOH-mah-TYE-tiss) Inflammation of the mouth.

stress: (STRESS) The physical (gravity, mechanical, pathogenic, injury) and psychological (fear, anxiety, crisis, joy) forces that are experienced by individuals.

stressor: (STRESS-ur) Any person or situation that produces an anxiety response.

striae: (STRYE-ee-ee) A line or band of elevated or depressed tissue; may differ in color or texture from surrounding tissue.

subarachnoid: (SUB-uh-RAK-noyd) Below or under the arachnoid membrane and the pia mater of the covering of the brain and spinal cord.

subdural: (sub-DUHR-uhl) Beneath the dura mater.

subjective data: (sub-JEK-tiv DAY-tuh) Information that is provided verbally by the patient.

suffering: (SUFF-ur-ing) A state of severe distress associated with events that threaten the intactness of the person. Emotional pain associated with real or potential tissue damage.

summons: (SUM-muns) A notice of suit.
thrombophlebitis: (THROM-buh-fleh-BYE-tiss) The formation of a clot within a vein.
thrombosis: (throm-BOH-siss) Formation, development, or presence of a thrombus, an aggregation of blood factors.
tidaling: (TYE-dah-ling) Rise and fall; may refer to water in water-seal chamber of a chest drainage system.
titration: (tye-TRAY-shun) Adjustment of medication up or down to meet patient needs.
tolerance: (TALL-er-ens) The response of the body to medication that requires increased medication administration to achieve the same effect. Often refers to opioids.
torts: (TORTS) Lawsuits involving civil wrongs.
toxemia: (toh-SEE-me-ah) Spread of the poisonous products of bacteria throughout the body.
tracheostomy: (TRAY-key-AW-tuh-me) An opening in the neck into the trachea.
transillumination: (TRANZ-uh-lum) The passage of strong light through a body structure to permit inspection of an observer on the opposite side.
transmyocardial: (TRANS-mee-oh-KAR-dee-yah) Across all layers of the heart.
trauma: (TRAW-mah) Physical injury caused by an external force.
Trendelenburg’s position: (tren-DEL-uhn-burg PEE-si-uh-shun) A position in which the patient’s head is low and the body and legs are on an elevated and inclined plane.
triage: (TREE-ahj) The assignment of degrees of urgency to wounds or illnesses to decide the order of treatment of patients or casualties.
trichinosis: (TRICK-in-OH-siss) A disease caused by the roundworm Trichinella spiralis, which is spread by eating raw or undercooked meat from pigs or wild animals that contains Trichinella larvae.
trigeminus: (try-JEM-ih-nuh) Occurring every third beat, as in trigeminal premature ventricular contractions.
tropia: (TROH-pee-ah) A manifest deviation of an eye from the normal position when both eyes are open and uncovered.
T-tube: (TEE-tooh) A T-shaped tube in the bile duct that allows drainage of bile following gallbladder surgery.
tumor: (TOO-mur) An abnormal growth of cells or tissues; tumors may be benign or malignant.
turibid: (TER-bid) Cloudy.
turgor: (TER-gur) The resistance of the skin to being grasped between the fingers. Dehydration causes poor skin turgor.
unifocal: (YOO-nih-FOH-kuhl) Coming or originating from one site or focus.
upper gastrointestinal (upper GI, UGI) series: (UH-per GAS-troh-in-TES-ih-nuh SEER-ees) X-ray and fluoroscopic examinations of the stomach and duodenum after the ingestion of a contrast medium.
uremia: (yoo-REE-mee-ah) An excess in amino acid metabolism.
urethritis: (yoo-REE-mee-ah) An inflammation of the urethra.
urinary incontinence: (YOOR-ih-nahr-een-een-ee) Inability to control urine excretion creating accidental urinary leakage.
urodynamic: (YOO-roh-dye-NAHM-ik) The study of the holding or storage of urine in the bladder, the facility with which it empties, and the rate of movement of urine out of the bladder during urination.
uroscopy: (YOO-roh-SEP-siss) Septicemia resulting from urinary tract infection.
uricaria: (UR-TEH-CARE-ee-uh) Hives resulting from an allergic reaction.
utilitarian: (YOO-tih-LILL-ih-ah-TER ee-en) Consequent assessment of outcomes is the most important element.
vaginosis: (VAY-JEE-nuh-NYE-tiss) Inflammation of the vagina caused by Gardnerella vaginalis.
values: (VAL-uhs) Ideals or concepts that give meaning to an individual’s life.
vavolotomy: (VAW-vaw-tuh-mee) Cutting and sealing of the vas deferens to prevent sperm from getting outside the body. Used as a birth control method for men.
vector: (VEK-tur) Living organism that transmits disease.
venous stasis ulcers: (VEE-nus STAY-siss UL-ehs) Poorly healing ulcers that result from inadequate venous drainage.
ventricular diastole: (VEN-trik-yoo-lar-dye-AS-uh-lee) The period of relaxation of the two ventricles.
ventricular escape rhythm: (VEN-trik-yoo-lar es-KEEY-RITH-uhm) The naturally occurring rhythm of the ventricles when the rest of the cardiac conduction system fails.
ventricular repolarization: (VEN-trik-yoo-lar REE-pol-laht-ih-ZAY-shun) Reestablishment of the polarized state of the muscle after contraction.
ventricular systole: (VEN-trik-yoo-lar SIS-suhs-lee) The contraction of the two ventricles.
ventricular tachycardia: (VEN-trik-yoo-lar TAK-ih-kAR-dee-yah) A series of at least three beats arising from a ventricular focus at a rate greater than 100 beats per minute.
veracity: (VER-ah-sit-ee) Truthfulness.
verrucous: (ve-ROO-kus) Wartlike, with raised portions.
vertebrae: (VUR-tuh-BRAY) Any of the 24 bony segments of the spinal column: 7 cervical, 12 thoracic, 5 lumbar, and 5 sacral, and 4 coccygeal vertebrae.
vessicant: (VESS-ih-kant) Agent that causes blistering of tissue.
vescicular: (ve-SIK-yoo-lar) Pertaining to vesicles or small blisters.
virulence: (VEER-oo-lun) The power of an organism to cause disease.
virus: (VYE-rus) The smallest organism identified by use of electron microscopy; intracellular parasites that may cause disease.
viscosity: (vis-KAW-sih-tee) Thickness, the power of a fluid to resist shearing.
vesicles or small blisters.
virus: (VYE-rus) The smallest organism identified by use of electron microscopy; intracellular parasites that may cause disease.
vesicular: (ve-SIK-yoo-lar) Pertaining to vesicles or small blisters.
virulence: (VEER-oo-lun) The power of an organism to cause disease.
virus: (VYE-rus) The smallest organism identified by use of electron microscopy; intracellular parasites that may cause disease.
viscosity: (vis-KAW-sih-tee) Thickness, the power of a fluid to resist shearing.
