FIFTH EDITION
As new scientific information becomes available through basic and clinical research, recommended treatments and drug therapies undergo changes. The author(s) and publisher have done everything possible to make this book accurate, up to date, and in accord with accepted standards at the time of publication. The author(s), editors, and publisher are not responsible for errors or omissions or for consequences from application of the book, and make no warranty, expressed or implied, in regard to the contents of the book. Any practice described in this book should be applied by the reader in accordance with professional standards of care used in regard to the unique circumstances that may apply in each situation. The reader is advised always to check product information (package inserts) for changes and new information regarding dose and contraindications before administering any drug. Caution is especially urged when using new or infrequently ordered drugs.

Authorization to photocopy items for internal or personal use, or the internal or personal use of specific clients, is granted by F.A. Davis Company for users registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided that the fee of $.25 per copy is paid directly to CCC, 222 Rosewood Drive, Danvers, MA 01923. For those organizations that have been granted a photocopy license by CCC, a separate system of payment has been arranged. The fee code for users of the Transactional Reporting Service is: 8036-4068-9/+. $25.
For practical and vocational nursing students: you are valuable members of the health care team. We trust this text will help you learn to think like nurses and become safe practitioners.

To Dimitri, our angel, always in our hearts.
— Linda

And for Dave, who tried really hard to cook and manage the household while I worked on this edition.
— Paula
Welcome to the fifth edition of *Understanding Medical Surgical Nursing*! We have fully updated the material and have added exciting new information on evidence-based practice, safety, and more. Boxed materials throughout the text present actual evidence-based care guidelines.

We continue to work hard to provide a text written at an understandable level, with features that help students understand, apply, and practice the challenging content required to function as practical/vocational nurses. We are thankful to the many students who tell us they find the book very readable, and actually enjoyable. We have been overjoyed to hear from several nursing programs that their NCLEX scores soared after adopting this textbook. We welcome and value your comments on this edition.

We continue to emphasize understanding, critical thinking, and the ability to make sound clinical judgments. We believe that a student who learns to think critically will be better able to apply information to new situations. We hope both students and instructors find this fifth edition a practical tool for learning and understanding the principles of medical-surgical nursing.

**Features of the Book**

We have kept our most popular features from the first four editions along with new ones based on reader input.

**Newly Added:**

- Learning Outcomes to guide reading and studying.
- An exciting new way to review anatomy and physiology with more images and less text in each function and assessment chapter.
- A Diagnostic Tests Appendix with explanations of common tests for easy reference.
- Updated design for easier readability of tables and care plans.

Based on feedback, we have kept and expanded the following:

- Web links in the text to help students do further research on topics of interest. Every effort was made to use only major, established Web sites that are unlikely to change in the near future.
- One of our most popular features, Critical Thinking Exercises. These exercises help students practice and think about what they are learning.
- Review questions at the end of each chapter. Questions have been updated and include application- and analysis-level questions, and alternate format items to reflect the NCLEX-PN.
- Suggested Answers for the Critical Thinking Exercises and Review Questions. Research supports the importance of immediate feedback to reinforce learning, so we feel strongly that students should have access to correct answers while they are studying, without having to wait for their next instructor contact. Because there can be many answers to some of the critical thinking questions, we have provided sample answers to help stimulate students’ thinking.
- Nursing Care Tips, Be Safe!, and Learning Tips help make learning easy. The Joint Commission’s National Patient Safety Goals are reflected in many of the safety tips.
- Pronunciation keys for new words at the beginning of each chapter.
- Word-building footnotes throughout the chapters.
- Nursing care plans with gerontological considerations. These have been updated to reflect current practice.
- Boxed presentations of Cultural Considerations, Evidence-Based Practice, Gerontological Issues, Home Health Hints, and Nutrition Notes. Additional boxes have been added where needed.
- A comprehensive, updated glossary of new words is included in the appendix.

**To Students: How to Use This Book**

Learning outcomes are provided for each chapter. Review them before reading and then go back and check to be sure you understand them.

You will find a list of new words and their pronunciations at the beginning of each chapter. These words appear in bold at either their first use or most relevant use in a chapter, and they also appear in the glossary at the end of the book. By learning the meanings of these words as you encounter them, you will increase your understanding of the material. Many of these words are also broken down where they are used, so you can see how the parts of each word make up the whole.

You also will find learning tips to increase your understanding and retention of the material. You may want to develop your own memory techniques in addition to those provided. (If you think of a good one, send it to us and you may find it in the next edition!) Many of the learning tips have been developed and used in our own classrooms. We find them helpful in fostering understanding of complex concepts or as memory aids. However, we want to stress that memorization is not the primary focus of the text but rather a foundation for understanding and thinking about more complex information. Understanding and application will serve you far better than memorization when dealing with new situations.

Each chapter includes brief critical thinking case studies designed to help you apply material that has been presented. A series of questions related to the case will help you integrate the material with what you already know. These questions emphasize critical thinking, which is based on a foundation of recall and understanding of material. To enhance your learning, try to answer the questions before checking the answers.
Generic medication names are a must for you to know for NCLEX-PN. We continue to provide both the generic and trade names for medications to help you prepare for both the NCLEX and nursing practice.

Review questions appear at the end of each chapter to help you prepare for chapter tests, and also for the NCLEX-PN. Again, to assess your learning, try to answer the questions before looking up the answers at the back of the book.

Chapter reference lists provide sources for additional reading material. Websites have been included in many chapters. We believe it is important for you to interact with current technology to expand your information resources.

The following appendices are included for easy reference:

- Normal adult reference laboratory values
- Answers with rationales to chapter review questions
- Common medical abbreviations
- Common prefixes and suffixes to help learn word-building techniques
- Glossary of new words
- Common diagnostic tests

**Student Resources**

There is an abundance of additional student resources for this edition of *Understanding Medical Surgical Nursing* from the exercises in the accompanying Student Workbook to the digital assets found on DavisPlus (access code is available on the inside front cover of your book). The **Chapter Resource Guide** found on DavisPlus provides colorful and informative maps for each chapter outlining the specific resources.
Materials will be posted by type of resource as well as by chapter. Since topics are covered across multiple chapters you may find resources in multiple chapters. Take some time to click around DavisPlus and see all that is offered.

- **Pre-test and Post-test.** Do a pre-reading knowledge check with the pre-test and a post-reading understanding check with the post-test. The tests have the same questions so you can gauge your progress from start to finish. *Included for every chapter.*
- **Audio Case Study with Questions.** Chapter topic case scenarios in audio format with critical thinking questions for thought and discussion. *Included for every chapter.*
- **Animations & Media Bank.** Visual and audio enhancement of topics and concepts. *Included in relevant chapters and posted by resource.*
- **Procedures.** Selected LPN skills for you to review. *Included in relevant chapters and posted by resource.*
- **Interactive Exercises: Case Study, Fill-in-the-Blank, Flash Cards.** Included for every chapter. *Picture Match* is included for relevant chapters.
- **Interactive Clinical Scenarios (ICS).** Hone your critical thinking skills and make decisions for your patient based on the scenarios presented. Topics include dementia, chest pain, respiratory distress, and others. *Included in relevant chapters and posted by resource.*
- **Patient Teaching Guidelines.** Sample guidelines for disorders discussed throughout the text. These guidelines are printable for you to use in patient care settings while teaching your patients. *Included in relevant chapters and posted by resource.*
- **Student Question Bank.** NCLEX-PN–style review questions for each chapter. These questions have been reviewed and revised by an item-writing expert. *Posted by resource.*
- **Additional Bibliographic Resources.** Additional resources to enhance your learning of the chapter. *Included in relevant chapters.*

In addition you’ll also find the following resources to help you as you work through the chapters: audio glossary, concept map generator, medications and calculations problems, dosage calculation quizzes, syringe exercises, sample clinical simulation, and an NCLEX prep guide.

A paperback Student Workbook is available to provide additional practice with the material. Each chapter includes vocabulary practice, objective exercises, a case study or other critical thinking practice exercises, and review questions written in NCLEX-PN format. These questions have been updated by an item-writing expert. Workbook answers are posted to the instructor’s DavisPlus site. Ask your instructor(s) for the answers as appropriate.

**Instructor Resources**

Instructors have access to all student resources as well as materials specifically available to them to aid in the instruction of the material.

- **Instructor’s Guide.** Each chapter has a chapter outline with suggested classroom strategies and activities. Also included are student activities for printing and using for individual practice or for collaborative learning activities. These activities help the student to interact with the material, understand it, and apply it. Many of the activities are based on real patient cases and have been used with our own nursing students. Feedback from students has helped to refine the exercises. We believe the use of collaborative learning has greatly enhanced our students’ success in achieving their educational and licensure goals. Another benefit is the sense of community the students develop as a result of working in groups. A brief introduction and guidelines for using collaborative learning techniques is included.
- **PowerPoint Presentations.** For the instructor’s convenience there is a comprehensive *PowerPoint* program for classroom presentations. Images from the text are included in the presentations. Review questions have been added to the end of the presentations for a quick in-class knowledge check. Each presentation can be modified, reduced, or expanded by individual instructors to suit their needs.
- **Electronic Test Bank.** Test questions for each chapter and topic that assist students to prepare for the NCLEX-PN. These questions have been updated, enhanced, and expanded by an item-writing expert for this edition. As outlined in the NCLEX-PN test plan, the questions are in multiple choice and alternate formats, and they test understanding, application, and analysis of material. The program allows instructors to choose and modify the questions that best suit their classroom needs.
  - We include a *PowerPoint tutorial* and NCLEX-style *item-writing tutorial* to help you individualize our resources to your own needs.
- **Audio Case Study Q&A.** Discussion questions with suggested answers for the Audio Case Studies. *Instructors can access the audio in the Student Resources.*
- **Ethical Considerations.** Ethical scenarios with discussion questions and answers to use as case studies for classroom discussion.
- **Student Workbook.** Workbook answers are posted on the instructor’s DavisPlus site. Provide answers to students as appropriate.

In addition to all of these great resources for students and instructors, you’ll also each have access to a Davis Digital Version of the text so you can “take it on the go!”
Acknowledgments

Many people helped make this book a reality. First and foremost are the students, who provide us with the inspiration to undertake this project. We hope that students everywhere continue to find this text worth reading.

The F.A. Davis Company is an exceptional publishing partner. We feel fortunate to have had their continued enthusiasm and confidence in our book. The staff at F.A. Davis has guided us through this project for five editions to help us create a student-friendly book that truly promotes understanding of medical-surgical nursing.

Lisa Houck, Robin Richman, Elizabeth Hart, and many others have been extremely patient and kind as we worked hard to provide a quality text.

Contributors from across the United States, including many well-known experts in their fields, brought expertise and diversity to the content. Their hard work is much appreciated.

Many of our coworkers have contributed to this book and given us ongoing encouragement and validation of the worthiness of this project. Betty Ackley, Marina Martinez-Kratz, Carroll Lutz, Erin Mazur, Sharon Nowak, and Barbara BerkeyPILE were especially helpful in providing material, advice, and encouragement.

We also thank several educators who have graciously provided input when we have needed it: Peggy Flener, Penny Snyder, and Terri Waisanen. Dawna Martich was a godsend as our item-writing expert for this edition. Finally, we are thankful to Gay Alcenius, PharmD, for her expertise in updating all medication materials.

We wish to thank everyone who played a role, however large or small, in helping us to provide a tool to help students realize their dreams of becoming LPN/LVNs. We hope this book will help educate nurses who can provide safe and expert care because we have helped them to learn to think critically and make sound clinical judgments.

Burns  247  
Hypothermia  248  
Nursing Process for the Patient With Hypothermia  248  
Frostbite  249  
Hyperthermia  250  
Nursing Process for the Patient With Hyperthermia  250  
Poisoning and Drug Overdose  251  
Nursing Process for the Patient With Poisoning and Drug Overdose  251  
Inhaled Poisons  251  
Injected Poisons  251  
Insect Stings or Bites  252  
Snakebites  252  
Near-Drowning  252  
Nursing Process for the Near-Drowning Patient  252  
Psychiatric Emergencies  253  
Nursing Process for the Patient With a Psychiatric Emergency  253  
Disaster Response  254  
Bioterrorism  254  
Recognition of Potential Bioterrorism Agents  254  
Smallpox/Variola Major  255  
Anthrax  255  
Plague  256  
Botulism  257  
Review Questions  258  

UNIT THREE  Understanding Life Span Influences on Health and Illness  

CHAPTER 14  Developmental Considerations in the Nursing Care of Adults  
Linda S. Williams  
Health, Wellness, and Illness  263  
The Nurse’s Role in Supporting and Promoting Wellness  263  
Developmental Stages  263  
The Young Adult  263  
The Middle-Aged Adult  264  
The Older Adult  265  
Chronic Illness  266  
Incidence of Chronic Illness  267  
Types of Chronic Illnesses  267  
Gerontological Influence  267  
Effects of Chronic Illness  268  
Health Promotion  272  
Nursing Care  273  
Review Questions  275  

CHAPTER 15  Nursing Care of Older Adult Patients  
Maryanne Pietraniec-Shannon  
What Is Aging?  277  
Physiological Changes  277
Contents

Autoimmune Disorders 352
Pernicious Anemia 352
Idiopathic Autoimmune Hemolytic Anemia 353
Hashimoto’s Thyroiditis 353

### UNIT SIX
**Understanding the Hematologic and Lymphatic Systems**

#### CHAPTER 27
**Hematologic and Lymphatic System Function, Assessment, and Therapeutic Measures**

Janice L. Bradford and Lucy L. Colo

- Normal Hematologic and Lymphatic System
  - Anatomy and Physiology | 549  |
  - Blood                  | 549  |
  - Lymphatic System       | 552  |
  - Aging and the Hematologic and Lymphatic Systems | 554  |
- Nursing Assessment of Hematologic and Lymphatic Systems
  - Lymphatic Systems      | 554  |
  - Health History         | 554  |
  - Physical Examination   | 555  |
- Diagnostic Tests for the Hematologic and Lymphatic Systems
  - Blood Tests            | 556  |
  - Coagulation Tests      | 556  |
  - Bone Marrow Biopsy     | 556  |
  - Lymphangiography       | 558  |
  - Lymph Node Biopsy      | 558  |
- Therapeutic Measures for the Hematologic and Lymphatic Systems
  - Blood Administration  | 558  |
  - Monitoring             | 559  |
- Review Questions                                                     | 561  |

#### CHAPTER 28
**Nursing Care of Patients With Hematologic and Lymphatic Disorders**

Lucy L. Colo

- Hematologic Disorders
  - Anemias                | 563  |
  - Polycythemia           | 571  |
- Hemorrhagic Disorders
  - Disseminated Intravascular Coagulation | 572  |
  - Idiopathic Thrombocytopenic Purpura | 573  |
  - Hemophilia             | 574  |
- Disorders of White Blood Cells
  - Leukemia               | 576  |
  - Multiple Myeloma       | 580  |
  - Pathophysiology        | 580  |
  - Etiology               | 581  |
  - Signs and Symptoms     | 581  |
  - Diagnostic Tests       | 581  |

### UNIT SEVEN
**Understanding the Respiratory System**

#### CHAPTER 29
**Respiratory System Function, Assessment, and Therapeutic Measures**

Paula D. Hopper and Janice L. Bradford

- Normal Respiratory System Anatomy and Physiology | 593  |
  - Nose and Nasal Cavities | 593  |
  - Pharynx                | 593  |
  - Larynx                 | 593  |
  - Trachea and Bronchial Tree | 593  |
  - Lungs and Pleural Membranes | 593  |
  - Mechanism of Breathing | 594  |
  - Transport of Gases in the Blood | 596  |
  - Chemical Regulation and Respiration | 596  |
  - Respiration and Acid–Base Balance | 596  |
- Effects of Aging on the Respiratory System | 597  |
- Nursing Assessment of the Respiratory System
  - System                  | 599  |

### UNIT ELEVEN
Understanding the Genitourinary and Reproductive System

#### CHAPTER 41
Genitourinary and Reproductive System Function and Assessment
Laura L. McCully, Michelle Johnson, and Janice L. Bradford

- Normal Genitourinary and Reproductive System Anatomy and Physiology
- Female Reproductive System
- Male Reproductive System
- Aging and the Reproductive System
- Female Reproductive System Data Collection
  - Normal Function Baselines
  - Health History
  - Breast Examination
  - Diagnostic Tests of the Breasts
  - Bone Health Assessment
  - Additional Diagnostic Tests of the Female Reproductive System
- Male Reproductive System Data Collection
  - Health History
  - Physical Examination
  - Testicular Self-Examination
  - Breast Self-Examination
  - Diagnostic Tests of the Male Reproductive System
- Review Questions

#### CHAPTER 42
Nursing Care of Women With Reproductive System Disorders
Laura L. McCully and Debra Perry-Philo

- Breast Disorders
  - Benign Breast Disorders
  - Malignant Breast Disorders
- Breast Modification Surgeries
- Menstrual Disorders
  - Flow and Cycle Disorders
  - Dysmenorrhea
  - Premenstrual Syndrome and Premenstrual Dysphoric Disorder
- Endometriosis
- Menopause

### Contents

- Irritations and Inflammations of the Vagina and Vulva

- **Chapter 12** Nursing Care of Patients Having Surgery 202
- **Chapter 13** Nursing Care of Patients With Emergent Conditions and Disaster/Bioterrorism Response 237

### UNIT THREE Understanding Life Span Influences on Health and Illness
- **Chapter 14** Developmental Considerations in the Nursing Care of Adults 262
- **Chapter 15** Nursing Care of Older Adult Patients 276
- **Chapter 16** Nursing Care of Patients at Home 295
- **Chapter 17** Nursing Care of Patients at the End of Life 305

### UNIT FOUR Understanding the Immune System
- **Chapter 18** Immune System Function, Assessment, and Therapeutic Measures 324
- **Chapter 19** Nursing Care of Patients With Immune Disorders 339
- **Chapter 20** Nursing Care of Patients With HIV Disease and AIDS 362

### UNIT FIVE Understanding the Cardiovascular System
- **Chapter 21** Cardiovascular System Function, Assessment, and Therapeutic Measures 388
- **Chapter 22** Nursing Care of Patients With Hypertension 417
- **Chapter 23** Nursing Care of Patients With Valvular, Inflammatory, and Infectious Cardiac or Venous Disorders 432
- **Chapter 24** Nursing Care of Patients With Occlusive Cardiovascular Disorders 462
- **Chapter 25** Nursing Care of Patients With Cardiac Dysrhythmias 499
- **Chapter 26** Nursing Care of Patients With Heart Failure 521

### UNIT SIX Understanding the Hematologic and Lymphatic Systems
- **Chapter 27** Hematologic and Lymphatic System Function, Assessment, and Therapeutic Measures 548
- **Chapter 28** Nursing Care of Patients With Hematologic and Lymphatic Disorders 562

### UNIT SEVEN Understanding the Respiratory System
- **Chapter 29** Respiratory System Function, Assessment, and Therapeutic Measures 592
- **Chapter 30** Nursing Care of Patients With Upper Respiratory Tract Disorders 625
- **Chapter 31** Nursing Care of Patients With Lower Respiratory Tract Disorders 641

### UNIT EIGHT Understanding the Gastrointestinal, Hepatic, and Pancreatic Systems
- **Chapter 32** Gastrointestinal, Hepatobiliary, and Pancreatic Systems Function, Assessment, and Therapeutic Measures 686
- **Chapter 33** Nursing Care of Patients With Upper Gastrointestinal Disorders 717
- **Chapter 34** Nursing Care of Patients With Lower Gastrointestinal Disorders 744
- **Chapter 35** Nursing Care of Patients With Liver, Pancreatic, and Gallbladder Disorders 779

### UNIT NINE Understanding the Urinary System
- **Chapter 36** Urinary System Function, Assessment, and Therapeutic Measures 810
- **Chapter 37** Nursing Care of Patients With Disorders of the Urinary System 835
## UNIT TEN  Understanding the Endocrine System  871

| Chapter 38 | Endocrine System Function and Assessment | 872 |
| Chapter 39 | Nursing Care of Patients With Endocrine Disorders | 887 |
| Chapter 40 | Nursing Care of Patients With Disorders of the Endocrine Pancreas | 914 |

## UNIT ELEVEN  Understanding the Genitourinary and Reproductive System  941

| Chapter 42 | Nursing Care of Women With Reproductive System Disorders | 968 |
| Chapter 43 | Nursing Care of Male Patients With Genitourinary Disorders | 1004 |
| Chapter 44 | Nursing Care of Patients With Sexually Transmitted Infections | 1025 |

## UNIT TWELVE  Understanding the Musculoskeletal System  1043

| Chapter 45 | Musculoskeletal Function and Assessment | 1044 |
| Chapter 46 | Nursing Care of Patients With Musculoskeletal and Connective Tissue Disorders | 1059 |

## UNIT THIRTEEN  Understanding the Neurologic System  1095

| Chapter 47 | Neurologic System Function, Assessment, and Therapeutic Measures | 1096 |
| Chapter 48 | Nursing Care of Patients With Central Nervous System Disorders | 1118 |
| Chapter 49 | Nursing Care of Patients With Cerebrovascular Disorders | 1171 |
| Chapter 50 | Nursing Care of Patients With Peripheral Nervous System Disorders | 1192 |

## UNIT FOURTEEN  Understanding the Sensory System  1211

| Chapter 51 | Sensory System Function, Assessment, and Therapeutic Measures: Vision and Hearing | 1212 |
| Chapter 52 | Nursing Care of Patients With Sensory Disorders: Vision and Hearing | 1236 |

## UNIT FIFTEEN  Understanding the Integumentary System  1271

| Chapter 53 | Integumentary System Function, Assessment, and Therapeutic Measures | 1272 |
| Chapter 54 | Nursing Care of Patients With Skin Disorders | 1288 |
| Chapter 55 | Nursing Care of Patients With Burns | 1320 |

## UNIT SIXTEEN  Understanding Mental Health Care  1339

| Chapter 56 | Mental Health Function, Assessment, and Therapeutic Measures | 1340 |
| Chapter 57 | Nursing Care of Patients With Mental Health Disorders | 1355 |
unit ONE

Understanding Health Care Issues
KEY TERMS

assessment (ah-SESS-ment)
clinical reasoning (KLIN-ih-kull REE-zon-ing)
collaborative (koh-LAB-rah-tiv)
critical thinking (KRIT-ih-kull THING-king)
data (DAY-tuh)
evaluation (e-VAL-yoo-AY-shun)
evidence-based practice (EHV-ah-dense baste PRACK-tiss)
intervention (in-ter-VEN-shun)
nursing diagnosis (NER-sing DYE-ag-NOH-sis)
nursing process (NER-sing PRAH-sess)
objective data (ob-JEK-tiv DAY-tuh)
subjective data (sub-JEK-tiv DAY-tuh)
vigilance (VIJ-eh-lents)

LEARNING OUTCOMES

1. Explain why good critical thinking is important in nursing.
2. Describe attitudes and skills that promote good critical thinking.
3. Describe the thinking that occurs in each step of the nursing process.
4. Identify the role of a licensed practical nurse/licensed vocational nurse in using the nursing process.
5. Differentiate between objective and subjective data.
6. Document objective and subjective data.
7. Prioritize patient care activities based on Maslow’s hierarchy of human needs.
Excellent in the delivery of nursing care requires good thinking. Each day nurses make many decisions that affect the care of their patients. For those decisions to be effective, the thinking behind them must be sound.

**CRITICAL THINKING**

Nursing students must learn to think critically; in other words, to think like a nurse. This means they must use their knowledge and skills to make the best decisions possible in patient care situations. Halpern (1996) says that, “critical thinking is the use of those cognitive [knowledge] skills or strategies that increase the probability of a desirable outcome” (p. 5).

Good thinking in nursing care has also been called clinical reasoning. Hawkins et al (2010) define clinical reasoning as “thinking through the various aspects of patient care to arrive at a reasonable decision regarding the prevention, diagnosis, or treatment of a clinical problem in a specific patient.” Good thinking requires critical thinking attitudes and skills, which are described in this section. It also requires a good knowledge base, so your thinking is based on correct factual material. Our goal in this text is to provide you with solid medical-surgical knowledge on which to base good decisions.

**Critical Thinking Traits**

It is important for nurses to possess an attitude that promotes good thinking. Researchers have identified attitudes or traits associated with good critical thinking. The Foundation for Critical Thinking (2013) identifies seven traits: (1) intellectual humility, (2) intellectual courage, (3) intellectual empathy, (4) intellectual integrity, (5) intellectual perseverance, (6) faith in reason, and (7) fair-mindedness. We summarize these next.

**Intellectual Humility**

Have you ever known people who think they know it all? They do not have intellectual humility. People with intellectual humility have the ability to say, “I’m not sure about that. I need more information.” Certainly, we want our patients to think we are smart and know what we are doing, but patients also respect nurses who can say, “I don’t know, but I’ll find out.” It is unsafe to care for patients when you are unsure of what you need to do.

**Intellectual Courage**

Intellectual courage allows you to look at other points of view even when you may not agree with them at first. Maybe you really believe that 8-hour shifts are best for nurses, and you have a lot of good reasons for your belief. But if you have intellectual courage, you will be willing to really listen to the arguments for 12-hour shifts. Maybe you will even be convinced. Sometimes you have to have the courage to say, “Okay, I see you were right after all.”

**Intellectual Empathy**

Consider the patient who snaps as you enter her room, “I’ve been waiting all morning for my bath. If you don’t help me with it right now I’m going to call your supervisor.” The first response that comes into your head is, “I have five other patients; you’re lucky I am here!” If you have intellectual empathy, however, you will be able to think, “If I were this patient, who is in chronic pain and is tired of being in the hospital, how would I feel?” Such thinking might change how you respond.

**Intellectual Integrity**

One of your patients asks a hundred questions when you bring her a medication that has been newly prescribed for her high blood pressure. But later you notice she is taking an herbal remedy from her purse. It is good that she asks a lot of questions about her drug, which has been tested extensively by the Food and Drug Administration (FDA). Herbal remedies, however, are not held to the same standards as medications in the United States. Someone with intellectual integrity would want the same level of proof applied to both medications and herbal remedies to determine if they are safe and effective before using them.

**Intellectual Perseverance**

Perseverance means you do not give up. Consider this scenario: You have concerns about some side effects you noticed after giving a new drug to a patient. You mention it to the health care provider, who says not to worry about it, but you are still concerned. If you have intellectual perseverance, you might do some research on the Internet, then go to your supervisor or the pharmacist to further discuss your concerns.

**Faith in Reason**

If you have faith in reason, you believe in your heart that good clinical reasoning will result in the best outcomes for your patients. And if you really believe, you will be more likely to attend a seminar or read an article on developing your clinical reasoning skills.

**Fair-Mindedness**

One of your coworkers wants to change the medication administration schedule on your unit. She says it will be better for the patients, but you think it might be because it is a better fit for her coffee-break schedule. If you have an intellectual sense of justice, you will be sure that your thinking is not biased by something that you just want for yourself, as seems to be happening with your coworker. You should examine your own motives as well as those of others when you are making decisions.

So what does all this mean to you as a nursing student? The term metacognition means to “think about thinking.” It is important for you to try to develop the attitudes of a critical thinker and to learn to think clearly and critically about your patient care. To do that, you need to constantly reflect on how you are thinking. Are you practicing intellectual humility? Are you trying to be courageous and empathetic? These attitudes create an excellent base on which to build nursing knowledge and develop further thinking skills.
Nursing Knowledge Base

Nurses must have a solid knowledge base to safely care for patients. You would not drive a car without first learning the basics of how a car works and the rules of the road. In the same way, you must understand the human body in health and illness before you can understand how to take care of an ill patient. This is the reason you are going to school and studying this book.

Information is found in many places; some information is good, and some is not as good. For example, health information found on a website may have been put there by a major university medical school or other reputable source, or it may have been put there by a patient who has a particular disorder. You may learn about a patient’s experience by reading his or her website, but you certainly would not base your patient care on someone’s personal story.

The best knowledge on which to base your practice comes from research. Nurse researchers try new methods of caring for patients and compare them with traditional methods to determine what works best. For example, for many years, nurses were taught to massage patients’ reddened bony prominences to prevent pressure ulcers. Through research, we now know that this practice should be avoided because it can further harm the damaged tissue. When nursing care is based on good, well-designed research studies, it is called evidence-based practice. You will read more about evidence-based practice in Chapter 2.

Critical Thinking Skills

Problem Solving

Problem solving is another way to think about clinical reasoning. Nurses solve problems every day. However, a problem can be handled in a way that may or may not help the patient. For instance, consider Mr. Frank, who is in pain and asks for pain medication. You check the medication record and find that his analgesic is not due for another 40 minutes. You can choose to manage this problem in several ways. One approach is to tell Mr. Frank that it is not time for the pain medication and that he will have to wait. This may solve your problem (you can move on to the next patient), but it does not solve the problem in an acceptable way for Mr. Frank. He is still in pain! Another approach is to use a standard problem-solving method: (1) gather data, (2) identify the problem, (3) decide what outcome is desirable,

### LEARNING TIP

Each time you exit a patient’s room, do a mini critical thinking assessment. Think, “Did I ask the right questions? Was my thinking clear and logical? Is there anything I could have done better?”

This 1-minute metacognition exercise will help you develop as a great thinker!

1. Gather data, or factual information, to help you think critically about Mr. Frank’s request for pain medication. As a good critical thinker, you can use intellectual empathy as well as your knowledge base about pain to decide what data you need. You decide to use a pain-rating scale on which the patient rates pain on a scale of 0 (no pain) to 10 (the greatest pain possible). Mr. Frank says that the pain is in his back and rates it as an 8 on a 10-point scale. You check his history and find that he has spinal compression fractures. Your empathetic attitude tells you that waiting for 40 minutes to relieve his pain is not acceptable. You next go to the medication record and find that he has no alternative pain medications ordered.

2. Identify the problem. Here you use your knowledge base about compression fractures, pain, and medication administration to draw the conclusion that Mr. Frank is in acute pain, and the current medication orders are not sufficient to provide pain relief.

3. Decide what outcome (sometimes called a goal) is desirable. The outcome should be determined by you (the nurse) and the patient working together. The patient is intimately involved in this situation and deserves to be consulted. You may also collaborate with the RN or health care provider. In this case, you talk to Mr. Frank and determine that he needs pain relief now; he cannot wait until the next scheduled dose of medication. He states that he can tolerate a pain rating of 3 or less on a 10-point scale.

4. Plan what to do. Formulate and consider some alternate solutions. For example, you can decide to tell Mr. Frank that he has to wait 40 minutes; however, this will not help him reach his desired outcome of pain control. You could give the medication early, but this would not be following the health care provider’s orders and may have harmful effects for Mr. Frank. You could decide to try some nondrug pain-control methods, such as relaxation, distraction, or imagery. These might be helpful, but you recall from pharmacology class that complementary methods should be used in conjunction with, not in place of, medications. Another option is to report to the registered nurse (RN) or health care provider that Mr. Frank’s pain is not controlled with the current pain-control regimen. Once you have several alternative courses of action, decide which will best help the patient. Then you can discuss those options with the RN and together decide the best thing to do; in this case, you might decide to have the RN contact the health care provider while you work with the patient on relaxation exercises. You might decide...
to ask Mr. Frank if he would like to listen to some of the music his wife brought for him. You should also tell Mr. Frank that the health care provider is being contacted. This would assure him that his pain is being taken seriously.

5. Implement the interventions in your plan. The RN enters the room and informs you and the patient that the health care provider has changed the analgesic orders. You obtain and administer the first dose of the new analgesic, being sure to explain its effects and side effects to Mr. Frank. The RN also informs Mr. Frank that the health care provider has ordered a consultation with the pain clinic.

6. Evaluate the plan of care. Did the plan work? As you reassess Mr. Frank 30 minutes later, he rates his pain level at 2 on the 10-point scale. He smiles and thanks you for your attentiveness to his needs. You think back to the desired outcome, compare it with the current data collected, and determine that your interventions were successful.

Can you see how using good thinking attitudes, a good knowledge base, and the problem-solving process led to a better outcome than simply choosing the first obvious option? You were able to achieve a desirable outcome: assisting Mr. Frank in relieving his pain. And you have earned Mr. Frank’s trust in the process. Problem solving is how nurses make decisions on a daily basis. You have earned Mr. Frank’s trust in the process. Problem solving is how nurses make decisions on a daily basis. You may already know this method as the nursing process.

Other Critical Thinking Skills

Problem solving is just one critical thinking skill. Another way you can use critical thinking in patient care is by anticipating what might go wrong, watching carefully for signs that a problem might be occurring, and then preventing it or notifying the RN or health care provider in time to intervene. Nurses save many lives each year by anticipating and preventing problems. Sometimes this is called vigilance. An example would be knowing the signs and symptoms of low blood glucose (because of an excellent knowledge base) and watching for them carefully (being vigilant) in a patient taking medication for diabetes. If early symptoms occur, you can intervene before the problem becomes severe. In addition, you could teach the patient and family about low blood glucose and how to prevent it, further reducing the risk to the patient.

There are many other thinking skills that are beyond the scope of this book. A few questions follow that you can ask yourself as you continue to develop your thinking skills. These are not in any order, nor would they all be asked for in a given situation. They are just some ideas to get you started.

- Have I thought this through?
- What information do I need?
- How do I know?
- Is someone influencing my thinking in ways I am not aware of?
- What conclusions can I draw from the information I have?
- Am I basing this decision on assumptions that may or may not be true?
- Am I thinking creatively about this, or am I in a rut?
- What do I need to watch for in order to prevent complications?
- Is there an expert I can consult who can help me think this through?
- Is there any supporting research or evidence that this is true?
- Am I too stressed or tired to think carefully about this right now?

NURSING PROCESS

You have just used the nursing process to solve a real problem. The nursing process is an organizing framework that links the process of thinking with actions in nursing practice. The nursing process is used to assess patient needs, formulate nursing diagnoses, and plan, implement, and evaluate care. As a nursing student, you consciously apply the nursing process to each patient problem. With experience, you will internalize the nursing process and use it without as much conscious effort.

Role of the Licensed Practical Nurse/Licensed Vocational Nurse

The licensed practical nurse (LPN) or licensed vocational nurse (LVN) carries out a specific role in the nursing process, as described in Table 1.1. The role of the LPN/LVN is to provide direct patient care. The LPN/LVN often spends more time at the bedside than the RN, which allows the LPN/LVN to develop a therapeutic relationship and understand the patient’s needs. The LPN/LVN and the RN collaborate to analyze data and develop, implement, and evaluate the plan of care (Fig. 1.1).

Data Collection

The first step in the nursing process is data collection. This assessment is a way to evaluate a patient’s condition. The LPN/LVN assists the RN in collecting data from a variety of sources. Data are divided into two types: subjective data and objective data.

Subjective Data

Information provided verbally by the patient is called subjective data. Symptoms are subjective data. Anxiety or pain
would be considered subjective data because only the patient can feel them. A nurse cannot objectively observe them. Often, subjective information is placed in quotes, such as “I have a headache” or “I feel out of breath.” You must listen carefully to the patient and understand that only the patient truly knows how he or she feels.

When collecting subjective data, start with the patient’s main concern. Focus on the reason the patient is seeking health care. Try asking, “What happened that brought you to the hospital (clinic, office)?” Once the patient has identified the main concern, further questioning can reveal more pertinent information. Use the phrase “WHAT’S UP?” as a handy way to remember questions to ask the patient (Box 1-1). Asking the right questions can help you obtain better data with which to make the best decisions.

### Box 1-1 WHAT’S UP? Guide to Symptom Assessment

W—Where is it?  
H—How does it feel? Describe the quality. (For example, is it dull, sharp, stabbing?)  
A—Aggravating and alleviating factors. What makes it worse? What makes it better?  
T—Timing. When did it start? How long does it last?  
S—Severity. How bad is it? This can often be rated on a scale of 0 to 10.  
U—Useful other data. What other symptoms are present that might be related?  
P—Patient’s perception of the problem. The patient often has an idea about what the problem is, or the cause, but may not believe that his or her thoughts are important to share unless specifically asked.

Next, obtain a patient history. Do this by asking the patient and family questions about the patient’s past and present health problems, including specific questions about each body system, family health problems, and risk factors for health problems. The patient’s medical record may also be consulted for background history information.

### LEARNING TIP

Practice assessing a symptom on a classmate. Ask the WHAT’S UP? questions.

In addition to assessment of physiological function, ask the patient about personal habits that relate to health, such as exercise, diet, and the presence of stressors, according to institutional assessment guidelines. Finally, assess the patient’s family role, support systems, and cultural and spiritual beliefs.

### Objective Data

**Objective Data** are pieces of factual information obtained through physical assessment and diagnostic tests that are observable or knowable through the five senses. For example, a rash can be observed with the eyes and palpated with the fingers. Objective data are sometimes called **signs**. Examples of objective data include the following:

- 3-cm red lesion
- Respiratory rate 36 per minute
- Blood glucose 326 mg/dL
- Patient is moaning

These are all observable or measurable by a nurse and do not need explanation by the patient.
Objective data are gathered through physical assessment. Inspection, palpation, percussion, and auscultation techniques are used to collect objective data (Fig. 1.2). You can find more on these techniques, as well as how to obtain a complete history, in a nursing assessment text. Give special attention to areas that the patient has identified as potential problems.

**Documentation of Data**

Collected data are documented in the patient’s medical record. If you identify any significant problem, change in the patient’s status, or variation from normal, report it immediately to an RN or health care provider and then document it. Recorded data should be accurate and concise.

When documenting subjective data, use what was stated by the patient or significant other. Use direct quotations whenever possible, such as, “I feel sad.” Quotes accurately represent the patient’s view and are least open to mistaken interpretation.

When documenting objective data, include exactly what you observed. Avoid interpreting the data and using words that have vague meanings. For example, “nailbed color is pink” gives clearer information than “nailbed color is normal.” “Normal” is an interpretation of data, rather than true data. “Capillary refill is 2 seconds” is more precise than “capillary refill is good.” The statement “the wound looks better” is not meaningful unless the reader has previously observed the wound. Stating that “the wound is 1 by 2 inches, red, with no drainage or odor” provides data with which to compare the future status of the wound and determine whether it is responding to treatment.

**Nursing Diagnosis**

Once data have been collected, the LPN/LVN assists the RN to compare the findings with what is considered “normal.” Data are then grouped, or clustered, into sets of related information that identify problems. Problems are then labeled as nursing diagnoses.

According to the North American Nursing Diagnosis Association (NANDA-I), a **nursing diagnosis** is a “clinical judgment about actual or potential individual, family, or community responses to health problems or life processes.” A nursing diagnosis provides the basis for selection of nursing interventions to achieve outcomes for which the nurse has accountability” (NANDA-I, 2013). Nursing diagnoses are standardized labels that make an identified problem understandable to all nurses. A list of NANDA-I–approved nursing diagnoses can be found in Appendix A of this book.

A diagnosis is considered “medical” when the health care provider directs most of the care. A diagnosis is considered “nursing” if the interventions needed to treat the problem are mainly independent nursing functions.

One example of a NANDA-I nursing diagnosis is **Acute Pain**. In Mr. Frank’s example, the nurse identified that pain was a problem, and a plan of care was developed to manage the pain. The health care provider was contacted for analgesic orders, but independent nursing actions were also used, including relaxation and distraction. These independent nursing actions did not require a health care provider’s order.

A well-written nursing diagnosis helps guide development of a plan of care. The three parts of a diagnosis follow:

- **Problem**—the nursing diagnosis label from the NANDA-I list
- **Etiology**—the cause or related factor (usually preceded by the words “related to”)
- **Signs and symptoms**—the subjective or objective data that provide evidence that this is a valid diagnosis (often preceded by the words “as evidenced by”)

The statement of problem, etiology, and signs and symptoms is called the **PES format**. Look again at the case study of Mr. Frank. A diagnosis using this format might read: “**Acute Pain** related to muscle spasms and nerve compression as evidenced by patient’s pain rating of 8 on a 10-point scale.” Note how the complete diagnosis gives you more helpful information than simply the label “pain.” This additional information helps determine an appropriate outcome and guides the selection of interventions.

Many patient problems are **collaborative**—that is, the nurse, health care provider, and other members of the health team all work together to reach the desired outcome. For example, a patient with pneumonia (a medical diagnosis) has many needs that depend on health care provider orders, such as respiratory treatments and antibiotics. The role of the LPN/LVN is to collect important data on the patient’s respiratory status and to provide nursing measures such as encouraging fluid intake, coughing, and deep breathing.
Planning Care

Once nursing diagnoses have been identified, an individualized plan of care is designed to help meet the patient’s care needs. Planning involves setting priorities, establishing outcomes, and identifying interventions that will help the patient meet the outcomes. It is important to include the patient in the development of the plan of care. The plan will be most successful if the patient agrees with and understands the interventions.

Prioritize Care

Once you know what problems need to be addressed, you must decide which problem or intervention should be taken care of first. Because care should always be patient-centered, with the patient at the center of the health team, such decisions should involve the patient as well as the RN and LPN/L VN. Maslow’s hierarchy of human needs is one commonly used system that can be used as a basis for determining priorities (Fig. 1.3). According to Maslow, humans must meet their most basic needs (those at the bottom of the triangle) first. They can then move up the hierarchy to meet higher level needs.

Physiological needs are the most basic. For example, a person who is short of breath cannot attend to higher level needs because the physiological need for oxygen is not being met. Once physiological needs are met, the patient can concentrate on meeting safety and security needs. Love, belonging, and self-esteem needs are next; self-actualization needs are generally the last priority when planning care.

Throughout life, people move up and down Maslow’s hierarchy in response to life events. If a need occurs on a level below the patient’s current level, the patient will move down to the level of that need. Once the need is fulfilled, the person can move upward on the hierarchy again.

**FIGURE 1.3** Maslow’s hierarchy of human needs.

---

**CRITICAL THINKING**

**Nursing Diagnosis**

- Which of the following are NANDA-I nursing diagnoses? Which are medical diagnoses? (Hint: Check Appendix A for help figuring these out!)
  1. Impaired Physical Mobility
  2. Ineffective Coping
  3. Herniated Disk
  4. Fractured Femur
  5. Diabetes
  6. Impaired Gas Exchange
  7. Appendicitis
  8. Activity Intolerance

_Suggested answers are at the end of the chapter._
In a nursing plan of care, the patient’s most urgent problem is listed first. This usually involves a physiological need such as oxygen or water because these are life-sustaining needs. If several physiological needs are present, life-threatening needs are ranked first, health-threatening needs are second, and health-promoting needs, although important, are last.

Establish Outcomes
An outcome is a statement that describes the patient’s desired goal for a problem area. It should be measurable, be realistic for the patient, and have an appropriate time frame for achievement. *Measurable* means that the outcome is objective, or can be observed. It should not be vague or open to interpretation, with the use of subjective words such as normal, large, small, or moderate. Consider, for example, two outcomes:

1. The patient’s shortness of breath will improve.
2. The patient will be less short of breath within 15 minutes as evidenced by the patient rating the shortness of breath at less than 3 on a scale of 0 to 10, respiratory rate between 16 and 20 per minute, and relaxed appearance.

Although the first outcome seems appropriate, in reality it is difficult to know when it has been met. There is nothing to objectively indicate when the problem has been resolved. The second outcome is objective. You can see that when the patient rates his or her shortness of breath at less than 3, is breathing at a rate of 16 to 20 per minute, and appears relaxed, the desired outcome will have been met. The outcome is realistic, and the 15-minute time frame ensures that the patient’s distress is minimized. If the plan of care does not achieve the desired outcome in the given time frame, it should be evaluated and revised as needed.

When determining criteria for a measurable outcome, look at the signs and symptoms portion of the nursing diagnosis. The resolution of signs and symptoms identified in the NANDA-I nursing diagnoses is evidence that nursing interventions were effective. If the desired outcome is not achieved, the problem and interventions need reevaluation. Look at another outcome example to see how criteria are used for measurement:

*Nursing diagnosis*—*Ineffective Airway Clearance* related to excess secretions as evidenced by coarse crackles and nonproductive cough

**Outcome**—Patient will have effective airway clearance within 8 hours, as evidenced by clear lung sounds and productive cough.

**Identify Interventions**
Interventions are the actions you take to help a patient meet a desired outcome. Therefore, interventions should be goal-directed. Any intervention that does not contribute to meeting the outcome should not be part of the plan of care.

One way to create a care plan is to include interventions that can be categorized as “take, treat, and teach.” In the first intervention category, “take,” or identify, data related to the problem that should be routinely collected. Next, “treat” the problem by identifying deliberate actions to help reach the outcome. Last, identify what to “teach” the patient and family for the patient to learn to care for himself or herself.

Look again at the nursing diagnosis of *Ineffective Airway Clearance*. A plan of care for this problem using the take, treat, and teach method might look like this:

**Take:** Auscultate lung sounds every 4 hours and as needed.
Assess respiratory rate every 4 hours and as needed.
**Treat:**
Provide 2 L of fluids every 24 hours.
Offer expectorant as ordered.
Provide cool mist vaporizer in room.

**Teach:**
Teach the patient the importance of fluid intake.
Teach the patient to cough and deep breathe every 1 to 2 hours.

In addition to identifying interventions, it is important to understand how and why they will work. The “why” is called a rationale. For example, you should assess lung sounds and respiratory rate every 4 hours because increased crackles and respiratory rate indicate retained secretions. Fluids are provided to minimize mucosal drying and ease secretion removal. Sound rationales that are evidence based (research based) should guide the selection of each nursing intervention. You will find rationales with interventions throughout this book to help you understand why interventions will be effective.

Like nursing diagnoses, nursing interventions can be either independent or collaborative. Independent nursing actions can be initiated by the nurse. Examples of independent nursing actions include teaching the patient deep-breathing exercises, turning a patient every 2 hours, teaching about medications, and giving a back rub for comfort. Collaborative actions require a health care provider’s order to perform. Examples of collaborative interventions include giving prescribed medications, applying elastic stockings, requesting a referral to physical therapy, and inserting a urinary catheter.

**Implement Interventions**
Once the plan of care has been identified, it must be communicated to the patient, family, and health team members and then implemented. One way a plan of care is communicated is by writing it as a nursing care plan. The nursing care plan is documented on the patient’s medical record, to communicate to all nurses the patient’s priority problems, the desired outcomes, and the plan for meeting the outcomes. Many institutions have standardized care plans that are individualized for each patient by the nurse.

Implementation of the plan of care involves performing the interventions. The patient’s response to each intervention is noted and documented. This documentation provides the basis for evaluation and revision of the plan of care.

**Evaluate Outcomes**
The last step of the nursing process is evaluation. The nurse continuously evaluates the patient’s progress toward the desired outcomes and the effectiveness of each intervention. If the outcomes are not reached within the given time frame or if the interventions are ineffective, the plan of care is revised. Any part of the plan of care can be revised, from the diagnosis or desired outcome to the interventions. Acute care institutions require routine review and updating of the plan of care.

**SUGGESTED ANSWERS TO**

**CRITICAL THINKING**

**Nursing Diagnosis**
1. Impaired Physical Mobility = nursing
2. Ineffective Coping = nursing
3. Herniated Disk = medical
4. Fractured Femur = medical
5. Diabetes = medical
6. Impaired Gas Exchange = nursing
7. Appendicitis = medical
8. Activity Intolerance = nursing

**Prioritizing Care**
1. *Ineffective Airway Clearance*—physiological need that can be life threatening
2. *Constipation*—physiological need that can be health threatening
3. *Deficient Knowledge*—safety and security need
4. *Disabled Family Coping*—love and belonging need
5. *Readiness for Enhanced Self-Concept*—self-esteem need

**REVIEW QUESTIONS**

1. In which of the following ways is critical thinking useful to the nursing process?
   1. It highlights the solution to a problem.
   2. It can lead to a better outcome for the patient.
   3. It simplifies the process.
   4. It helps the nurse arrive at a solution more quickly.
2. Which nurse is exhibiting intellectual humility?
   1. The nurse who is an expert at wound care.
   2. The nurse who reports an error to the supervisor.
   3. The nurse who tries to empathize with the patient.
   4. The nurse who asks a coworker about a new procedure.
3. Which of the following pieces of information is considered objective data?
   1. The patient’s respiratory rate is 28.
   2. The patient states, “I feel short of breath.”
   3. The patient is short of breath.
   4. The patient is feeling panicky.

4. An LPN/LVN is collecting data on a newly admitted patient who has an ulcerated area on his left hip. It is 2 inches in diameter and 1 inch deep, with yellow exudate. Which of the following statements best documents the findings in the patient’s database?
   1. Wound on left hip, 2 inches diameter, 1 inch deep, infected
   2. Left hip wound is large, deep, and has yellow drainage
   3. Pressure ulcer on left hip, yellow drainage
   4. Wound on left hip, 2 inches in diameter, 1 inch deep, yellow exudate

5. A 34-year-old mother of three children is admitted to a respiratory unit with pneumonia. She has all the following problems. Based on Maslow’s hierarchy of needs, which problem should the nurse address first?
   1. Frontal headache related to stress of hospital admission
   2. Anxiety related to concern about leaving children
   3. Shortness of breath related to newly diagnosed pneumonia
   4. Deficient knowledge related to treatment plan

6. Place the steps of the nursing process in correct chronological order of use. Use all options.
   1. Nursing diagnosis
   2. Evaluation
   3. Assessment
   4. Planning care
   5. Implementation

7. Which of the following parts of the nursing process can be carried out by an LPN/LVN?
   1. Implementation of interventions
   2. Nursing diagnosis
   3. Analysis of data
   4. Evaluation of outcomes

8. Which of the following is a nursing diagnosis?
   1. Stroke
   2. Renal Failure
   3. Fracture
   4. Acute Pain

9. A nurse teaches a patient the importance of stopping smoking. Which of the following patient responses provides the best evidence that the teaching was effective?
   1. “I have a brother who died of lung cancer. I know smoking is bad.”
   2. “I tried to quit 5 years ago, and I really would like to, but it is very hard.”
   3. “Thank you for the information. I will call the Smoke Stoppers organization today.”
   4. “I know you are right; I should stop smoking.”

Answers can be found in Appendix C.

Evidence-Based Practice

KEY TERMS

evidence-based practice [EH-vo-dense based PRACK-tis]
randomized controlled trial [RAN-dumb-eyesd cun-TROLLD TRY-ull]
research [re-SURCH]

dsystematic review [SISS-tem-AT-ick re-VIEW]

LEARNING OUTCOMES

1. Define evidence-based practice (EBP).
2. Discuss why EBP should be used.
3. Explain how to identify nursing evidence that should be put into practice.
4. Describe the EBP process.
5. List the six steps of EBP.
6. Identify the best method for oral care.
7. Identify who should give evidence-based nursing care, including when and where care should be given.
8. Describe how the Quality and Safety Education for Nurses (QSEN) project can promote safe patient care.
Amanda, an LPN, is caring for residents on Unit 4 in an extended care agency. One of the residents, Mr. Samuel, had a right-sided stroke and currently has a gastrostomy tube through which a formula is administered 12 hours per day. He has halitosis, and his teeth look fuzzy. He currently receives oral care twice daily with oral foam swabs. Let’s explore with Amanda what the evidence says should be done for oral care for Mr. Samuel. (See discussion and answers throughout the chapter.)

Evidence-based practice (EBP) is a systematic process that employs current evidence to make decisions about patient care. It includes evaluation of the quality and applicability of existing research, patient preferences, costs, clinical expertise, and clinical settings (Melnik et al., 2010). Evidence gives assurance that nursing practice will be effective. Using evidence-based nursing practice will increase your power to give the best nursing care possible.

EBP involves much more than simply evaluating research (scientific study, investigation, or experimentation) to determine which results apply to nursing care. Clinical reality can be very different from a research setting. It could be unsafe to apply a research study that was done in a controlled laboratory environment to the very different environment found in an actual clinical situation. Or it could be unsafe to apply research results obtained on people of one age or medical diagnosis to those of another age or with multiple diagnoses. The context in which the evidence will be used must be considered. This includes the health care environment, the patient involved, the nurse’s expertise, and the cost. Using EBP is a complex process, but it is an important way to ensure quality care and optimal patient outcomes.

Reasons for Using EBP

The use of EBP allows nurses to give patients the best care possible, which is the goal of all caring nurses. The reasons given for nursing care used to be “This is how it was taught in nursing school,” “This is what they told us in orientation,” or “That’s the way it is done here.” Now the rationale behind the best nursing care is “Nursing care is based on evidence and how it applies to an individual patient in a specific setting.” EBP is considered the gold standard of health care.

Evidence-based outcome measurement is built into the EBP process as a way to measure and confirm the value of a change in nursing practice. For example, nurses are measuring the number of new pressure ulcers, new cases of pneumonia, and new urinary tract infections in health care settings. Measuring outcomes as a part of EBP reenergizes nursing by helping nurses see the results of their nursing care. Measured outcomes show nurses that they are giving the best care possible, based on the evidence available at the time.

Evidence comes from multiple sources. Medical research and research from many other professions such as psychology, gerontology, and social work are utilized, in addition to nursing research to develop EBP nursing care guidelines.

Identifying Nursing Evidence

How do you identify nursing evidence that should be put into practice? It depends in part on the strength of the evidence. Evidence ranges from strong to weak, and levels can be assigned to rate its strength and quality. The rating scale used to label the quality of evidence ranges from Level I to Level IV (Table 2.1). Level I is the best evidence. It includes systematic reviews and analysis of many high-quality randomized controlled trials (studies designed to assess the effects of a variable by randomly assigning subjects to experimental, placebo, or control groups). Level IV evidence is the weakest and includes the non–research-based opinions of experts or published but non–research-based clinical articles. Two of the best known sources for Level I evidence are the Cochrane Reviews (www.cochrane.org/reviews) for medical evidence and the

---

**TABLE 2.1 LEVELS OF EVIDENCE**

<tr>
<td></td>
<td>Evidence obtained from at least one well-designed randomized controlled trial. These are true experimental studies in which as many factors as possible that could falsely change the results are controlled.</td>
</tr>
<tr>
<td>Level III</td>
<td>Quasi-experimental studies</td>
</tr>
<tr>
<td></td>
<td>Evidence obtained from quasi-experimental research studies. These studies do not control factors that could falsely change the results and, as a result, are less predictive of effectiveness of nursing care.</td>
</tr>
<tr>
<td>Level IV</td>
<td>Expert opinion</td>
</tr>
<tr>
<td></td>
<td>Evidence from the opinion of authorities and/or reports of expert committees. Also nursing journal articles that are opinion based, not research based.</td>
</tr>
</tbody>
</table>
Evidence that guides nursing care can be used in two ways, generally based on whether the evidence is a dependent or an independent nursing intervention. Dependent nursing interventions are those that are delegated by a health care provider. Here any change in practice must go through a committee, such as the policy and procedure committee, to determine if it is appropriate for adoption. If the intervention is independent, however, the nurse can implement an evidence-based change based on personal knowledge of the value of the intervention, as long as the change is safe and cannot harm the patient. An example is the intervention of reality orientation. Excellent research shows that the use of reality orientation can improve thinking ability in patients with dementia and delirium. The nurse can implement this intervention independently because it does not require an order. Other intervention examples include the use of hand massage, music therapy, and other anxiety-relieving interventions.

A simplified version of the EBP process is discussed next and shown in Figure 2.1. The acronym “ASKMME!” is designed to help you remember the six essential steps: Ask, Search, thinkK, Measure, Make it happen, and Evaluate (Ackley et al, 2008).

Step 1: Ask the Burning Question
EBP begins with questioning the status quo, trying to solve a problem, or learning about new evidence that should be used in nursing practice. The initial question nurses often ask is, “Why do we do it that way?” or “How could we do this better?” Questioning the existing way of doing things is part of critical thinking. It helps ensure that the patient receives the best care possible. As a student nurse, you can do this as well.

For Mr. Samuel, in the case study at the start of the chapter, Amanda was motivated to find the best way to give oral care, because her instincts told her the current care was not effective. Amanda took her clinical question to the policy and procedure committee and, working with members, they began the evidence-based process to find the best way to give oral care to all tube-fed patients at their agency.

Step 2: Search for and Collect the Most Relevant and Best Evidence Available
A thorough search of the literature in the subject area needs to be conducted. As a student nurse, you will find medical librarians most helpful. It is important that you learn basic computer skills so that you also have the ability to search the nursing and medical literature. Several databases can help you find journal articles and reviews.

For nursing literature, the best known database is CINAHL, which stands for Cumulative Index to Nursing and Allied Health Literature (www.ebscohost.com/cinahl). CINAHL is available through college and hospital libraries. Evidence-based care sheets are available on CINAHL. These sheets summarize current best practice on a specific topic. For best practice nursing reviews, visit the Joanna Briggs Best Practices website, which may be available at the nearest nursing library.

For medical literature, the comprehensive Medline/PubMed database can be accessed at www.ncbi.nlm.nih.gov. Cochrane Reviews are a available at www.cochrane.org/reviews. An easy way to find Cochrane Reviews is to type in “Cochrane” when searching for a topic.

Amanda worked with a medical librarian and other members of her agency’s policy and procedure committee to conduct an EBP search on oral care. They then summarized the research articles they found in this area (Table 2.2).

Step 3: Think Critically
Always appraise the evidence you find for validity, relevance to the situation, and applicability. First, evaluate the quality of the evidence you find. It is helpful to determine the level of the evidence to make sure you have the best information available (see Table 2.1). Then, using critical thinking, evaluate the evidence as it applies to the individual patient or patient population, the clinical expertise of the nurse(s) involved, the values in the situation, and agency policies that affect making a change in practice.

### TABLE 2.2 ORAL CARE FOR PATIENTS WHO ARE BEING TUBE FED

<table>
<thead>
<tr>
<th>Study</th>
<th>Population</th>
<th>Interventions</th>
<th>Key Findings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pearson, L. S., &amp; Hutton, J. L. (2002). A controlled trial to compare the ability of oral foam swabs and toothbrushes to remove dental plaque. <em>Journal of Advanced Nursing</em>, 39(5), 480–489.</td>
<td>34 volunteers</td>
<td>Group 1 received oral care in the a.m. using a toothbrush. Group 2 received oral care in the a.m. using oral foam swabs.</td>
<td>Use of toothbrushes for oral care was much more effective than foam swabs in removing plaque from the teeth.</td>
</tr>
<tr>
<td>Leibovitz, A., Plotnikov, G., Habot, B., et al (2003). Pathogenic colonization of oral flora in frail elderly patients fed by nasogastric tube or percutaneous enterogastric tube. <em>Journal of Gerontology Series A: Biological Sciences and Medical Sciences</em>, 58(1), 52–55.</td>
<td>215 subjects (patients in long-term care facilities)</td>
<td>Group 1: Patients fed via nasogastric (NG) tube had 81% pathogenic bacteria in mouth. Group 2: Patients fed by percutaneous enterogastric (PEG) tube had 51% pathogenic bacteria in mouth. Group 3: Patients fed orally had 17.5% pathogenic bacteria in mouth.</td>
<td>Patients fed by NG tube had more pathogenic bacteria in their mouths than those fed by PEG tube or those fed orally. If oral secretions are aspirated, the risk of pneumonia increases.</td>
</tr>
</tbody>
</table>
Amanda found many research articles on the value of oral care, and the results were exciting. When the research was analyzed, it became obvious that tube-fed patients should have oral care with a soft bristle toothbrush and toothpaste. Because Mr. Samuels had trouble swallowing, it was also important that suction be readily available as oral care was given. Amanda discovered that there are suction toothbrushes and oral swabs for patients such as Mr. Samuels (Figure 2.2). The studies also found that inadequate oral care resulted in more than just halitosis and fuzzy teeth; it could result in pneumonia. Amanda felt a renewed sense of purpose.

**Step 4: Measure Outcomes Before and After Change**

Next, determine the patient outcomes that are likely to occur as a result of a change in nursing care. Usually, a small pilot study is done within the agency before any widespread change in practice is made. That way, it can be determined if the change will be effective, as intended, when the change is implemented across the agency.

The committee members decided to measure the number of new pneumonia cases in their agency, which is an important patient outcome.

**Step 5: Make It Happen**

Institute the desired change in nursing practice based on evidence. This is done through education and by setting up quality systems to ensure that the desired change is actually happening.

The policy and procedure committee developed an evidence-based procedure guideline for oral care of all patients, with a separate policy for tube-fed patients. The new policy and procedure was introduced and became a requirement for all patients at the agency. A quality audit was then done at intervals on selected patients to ensure the appropriate oral care was being given.

**Step 6: Evaluate the Practice Change**

Evaluation is the process used to determine if the change made a significant difference. What were the results of the initial small study? Was the change in practice effective in improving patient outcomes? If it did make a difference, was the difference worth the extra cost or time it required?

**Wow! Because of Amanda’s concern about oral care, a change had been made that improved the care for every patient. Also, after making the change in oral care and evaluating the outcome, it was clear that Amanda’s agency had a decrease in new-onset pneumonia. This was exciting and reinforcing to the committee, and especially to Amanda.**

### Who Should Provide Evidence-Based Nursing Care?

All nursing care should be based on use of appropriate evidence, including care provided by nursing assistive personnel such as Competency Evaluated Nursing Assistants (CENAs). Evidence-based care should be given at all times, if possible, and in all settings where nursing care is given. A good way to ensure that evidence-based care is provided by CENAs is to explain why the care should be given when the care is delegated. For example, when Amanda asks a CENA to give thorough oral care to a tube-fed patient with a toothbrush, she explains that research studies have shown that toothbrushing can help reduce the incidence of pneumonia in older adults. With this knowledge the CENA understands the importance of giving effective oral care.

### EBP, Quality, and Safety: They Belong Together!

Multiple quality initiatives are currently having a positive impact on health care. Insurance companies, businesses, patients, and the government are demanding quality care. All quality initiatives require collection of data, which is greatly facilitated by the health care agency having an EBP framework. Some quality initiatives are required, such as those of the Joint Commission that accredits health care agencies. Others are voluntary but desirable for the agency’s well-being. All quality initiatives should begin with a literature search to determine the most effective interventions.

### Quality and Safety Education for Nurses Project

The Quality and Safety Education for Nurses (QSEN) project focuses on nursing education that promotes the continual improvement of quality and safety in patient care. The goal is for students to develop understanding, attitudes, skills, and the desire to continually improve the quality and safety of patient care. Information on the QSEN project can be found at [http://qsen.org](http://qsen.org).

The development of teaching strategies for nursing students involves six areas of focus:

1. **Evidence-based practice**: Look for Evidence-Based Practice boxes throughout the book.
2. **Safety:** We all want our patients to be safe! Many interventions are available that can help us reach this goal. Look for Be Safe! throughout the chapters and the section on safety in Chapter 3.

3. **Teamwork and collaboration:** These are important aspects of providing safe, quality care. In Chapter 3, you are introduced to members of the health care team with whom you may work and collaborate. For example, you may talk with the pharmacist if you have a question about a patient’s medication to ensure it is given safely, or you might alert the registered nurse to a change in a patient’s vital signs so that the physician can be informed for treatment orders. This illustrates teamwork to ensure that the patient receives safe, high-quality care.

4. **Patient-centered care:** When collaborating on the development of nursing care plans, it is important to individualize interventions to provide patient-centered care. As nursing interventions are performed, they should meet the patient’s needs and preferred schedules rather than those of the institution or caregiver. You will find Nursing Care Plans throughout the chapters, but always remember that no plan fits all patients. You will always evaluate each suggested intervention to see if it fits your patient and then individualize it to the patient’s needs.

5. **Quality improvement:** Quality improvement (QI) is an ongoing process to improve patient care (see Fig. 3.3). You might participate in a QI project by collecting data, which is one aspect of a QI project.

6. **Informatics:** Informatics is a growing area in health care because of the increasing use of technology to provide safer care. Examples you may use include computerized medical records, medication dispensing systems, medication barcoding systems, or computerized resources.

**Concern for Patient Safety**

Safety is on everyone’s mind. Many people know of someone who has been affected by a medical error or who has been unhappy with his or her care. As a result, guidelines to reduce errors in health care and improve patient outcomes have been developed and based on evidence when available. The Joint Commission’s 2014 National Patient Safety Goals can be found at [www.jointcommission.org](http://www.jointcommission.org). As you will see at the website, these goals address care in various types of health care settings.

**BE SAFE!**

One important safety goal is to use at least two ways to identify patients—but not the patient’s room number or location—when providing care, treatment, or services. This is because wrong-patient errors occur in virtually all stages of diagnosis and treatment. The intent for this goal is twofold: first, to reliably identify the patient as the person for whom the service or treatment is intended; second, to match the service or treatment to that patient (© The Joint Commission, 2013. Reprinted with permission.).

You will find other 2014 Joint Commission national patient safety goals in the Be Safe! feature throughout the text of this book. These goals are included to increase your awareness and understanding of patient safety. They address important areas of concern, such as administering medications safely, identifying patients correctly, identifying operative sites correctly, improving communication, reducing fall injuries, and reducing the risk of infection in institutionalized older persons, to name a few. You will want to become familiar with them and to look for updates at the Joint Commission website. Of course, it takes critical thinking to use them at the right times and in the right circumstances. Using them appropriately helps you provide safer care with fewer errors. EBP is critical thinking at its finest, working to determine the best care for the patient based on the evidence. The evidence provides core information to direct safe, quality-driven, excellent patient care.

**REVIEW QUESTIONS**

1. The nurse requests the CENA to provide oral care to a patient. Which of the following methods of request by the nurse would be most appropriate to achieve evidence-based care?
   1. Request that oral care be given with use of a toothbrush and toothpaste.
   2. Instruct the CENA to give oral care using oral swabs to clean the teeth and mouth.
   3. Ask the CENA to have the patient use a mouthwash rinse for daily oral care.
   4. Explain that use of a toothbrush and toothpaste decreases pneumonia in older adults.

2. The nurse is contributing to the plan of care for a patient. In considering appropriate care, the nurse bases the care on which of the following to provide excellent care?
   1. Content taught throughout a nursing educational program.
   2. Orientation to the health care agency for new employees.
   3. A nurse’s personal judgment of what is best for each patient.
   4. Evidence that is evaluated for the health care agency and each patient.
3. A policy and procedure committee is reviewing evidence for a new policy. When considering the evidence, which of the following sources would generally be safest for a health care agency to implement?
   2. One randomized controlled trial.
   3. Four quasi-experimental studies that show similar results.
   4. The opinion of a national nursing expert on the subject.

4. The nurse reads about a research study that affects nursing care and could lead to decreased wound infections. Which of the following actions should the nurse take regarding the information in the study?
   1. Put the information into practice while performing wound care.
   2. Discuss the research with a trusted coworker and, if the coworker agrees, put the information into practice at work.
   3. Present the proposed practice change to the policy and procedure committee at work for evaluation and possible adoption.
   4. Do a journal search to look for similar studies, and if three similar studies are found, incorporate the information into practice.

5. A policy and procedure committee is revising the nursing intervention of insertion of a urinary catheter. Where should the committee begin looking for evidence to write an effective policy and procedure on this intervention?
   1. In current nursing skills textbooks.
   2. In nursing articles written by national nursing experts based on opinion.
   3. In research articles, preferably systematic reviews of randomized controlled trials.
   4. In the policies and procedures of other nursing facilities.

6. A nurse is preparing to give oral care to a patient who is receiving a tube feeding. Which of the following is the best evidence-based method to give oral care?
   1. Use oral foam swabs with mouthwash and then swab the teeth and the mouth.
   2. Use a soft toothbrush and toothpaste to brush the teeth.
   3. Use a tongue scraper to remove debris from the tongue twice daily.
   4. No oral care is needed for a patient who is receiving tube feedings.

Answers can be found in Appendix C.

Issues in Nursing Practice

LINDA S. WILLIAMS, MICHELLE BLOCK, AND JAMES SHANNON

LEARNING OUTCOMES

1. Identify factors influencing changes in the health care delivery system.
2. Describe safe health care practices.
3. Explain the significance of hospital-acquired conditions.
4. Describe four leadership styles.
5. Discuss the LPN/LVN role in leadership and delegation.
6. Describe the importance of ethics in health care.
7. Explain the steps of the ethical decision-making model.
8. Discuss moral distress and its effect on nursing care.
9. Identify where the regulation of nursing practice is defined.
10. Define the Health Insurance Portability and Accountability Act (HIPAA) of 1996.
11. Describe guidelines for professional use of social media.
12. Discuss how to provide quality care and limit liability.

HEALTH CARE DELIVERY

Health–Illness Continuum

The term health–illness continuum describes the continually shifting levels of health experienced by each person. One end of the continuum represents high-level health. The other end represents poor health and impending death. We all move about the continuum throughout our lives.

Health Care Delivery Systems

A focus on prevention and providing services from birth to death under one integrated system is being used by many health care systems. Hospital consolidations led to health care systems that can cover large geographic areas. Hospitals provide the integrated care delivery network for the system (Fig. 3.1).

Factors Influencing Health Care Change

Do you like change? Well, today’s health care delivery is being influenced by many evolving changes, which will have an impact on your career. Some examples of these changes include the 2010 Patient Protection and Affordable Care Act (discussed later); the expanding role of technology in health care including electronic medical records; mobile health with tablets, smartphones, and digital apps; telehealth with telephones and online video; remote patient monitoring; robotics; the use of evidence to guide practice (see Chapter 2); and antibiotic-resistant infectious organisms that continue to emerge. Nursing informatics is a specialty area that deals with the study and use of information technology within nursing practice. There are educational programs with majors in informatics to consider as you continue your education. The changing characteristics of the American population are also influencing health care delivery with increases in the size of the population, number of older adults, and population’s cultural diversity (U.S. Census Bureau, 2010). These and other changes make learning a constant need in today’s health care environment. We hope that you will be flexible and embrace change throughout your career!

EVIDENCE-BASED PRACTICE

Clinical Question
Does use of information technology in the form of an Interactive Preventive Health Record (IPHR) increase the use of preventative health services?

Evidence
4500 patients were randomly invited to use an IPHR that provided personal health records, education, and reminders. Use of preventative services significantly increased by 2.3% in those using the IPHR over those who were not. Furthermore, the number of patients who were up to date on all recommended preventative services was double in the IPHR group.

Implications for Nursing Practice
Encouraging the use of patient-centered interactive technology might help improve patient health.

REFERENCES

Safe Practice

Preventing harmful adverse events is a concern of several organizations that promote safe health care practices. A culture of safety should exist within the health care system and nursing. The Joint Commission’s National Patient Safety Goals are updated annually, and sentinel events identify safety concerns and the interventions for them (www.jointcommission.org). Examples of sentinel events are surgery on the wrong body part or death/loss of function associated with a fall within a facility.

The National Quality Forum (NQF) (2011) has identified “serious reportable events” (SRE). These 29 events that should not occur in various health care settings are found at www.qualityforum.org/Topics/SREs/List_of_SREs.aspx.

Medication errors are of primary concern, and interventions to prevent them are being researched and implemented. The Institute for Safe Medication Practices has interventions to reduce medication errors such as the Error-Prone Abbreviations List, Do Not Crush List, Drug Names Written With Tallman Letters, Letters to Distinguish between Similar Looking Drug Names to Prevent Giving the Wrong Drug, and High Alert Medications (http://ismp.org/default.asp). No
interruption zones with brightly colored tape or wearing bright color vests/sashes as an alert to void distractions are used at some agencies with great results. Distractions during medication administration can increase errors, so you should always stay focused and avoid interruptions during this time. Promote a culture of safety and ask your coworkers to avoid interrupting others during medication administration. Reducing errors requires everyone to be engaged and vigilant at all times during patient care.

**LEARNING TIP**

To learn more about safe health care practices, visit the Institute for Healthcare Improvement website at [www.ihi.org/IHI/Programs/IHIOpenSchool](http://www.ihi.org/IHI/Programs/IHIOpenSchool).

Did you know that a drug made for one type of administration route, such as intravenous (IV), cannot be safely given by another route such as by NG or PEG tube? Serious effects, including death, can occur because the drug dosages or drug makeup is specific to the route. Get a new order for an alternate route if needed to obtain the proper drug form. This website shows examples of adverse effects when drugs were given incorrectly. Keep your patients safe!

**ECONOMIC ISSUES**

**Patient Protection and Affordable Care Act**

Known in brief as the Affordable Care Act, the 2010 Patient Protection and Affordable Care Act’s phase-in continues through 2020 (Fig. 3.2). Its purpose is to provide insurance reforms that protect consumers from insurance industry abuses, reduce the cost of health care, increase the quality of health care, and increase health insurance availability for more Americans. Key changes of the act are listed in Table 3.1. For more information, visit [www.hhs.gov/healthcare](http://www.hhs.gov/healthcare).

**Medicare and Diagnosis-Related Groups**

Medicare was created in 1965 to provide health insurance as part of the Social Security Act. It is run by the U.S. government and covers all people aged 65 and older and people younger than age 65 who have disabilities and are eligible for Social Security. It is funded by a deduction from every person’s paycheck that is matched by the government. Several Medicare plan options are offered, including Original Medicare, Medicare Health Plans, and prescription drug coverage for everyone with Medicare. There are two parts of coverage in the Original Medicare plan. Part A covers inpatient hospital care, skilled nursing facilities, hospice services, and some home care. There is no premium or deductible for Part A. Part B is medical insurance that covers physician costs, outpatient services, some

**FIGURE 3.2** Key features of the Affordable Care Act. (From the U.S. Department of Health and Human Services, 2013.)

**TIMELINE**

- **October**: Open enrollment begins
- **January**: Coverage begins
- **March**: Open enrollment closes
- **Future**: All Americans have access to affordable health care

**Benefits for Women**

Providing insurance options, covering preventive services, and lowering costs.

**Young Adult Coverage**

Coverage available to children up to age 26.

**Strengthening Medicare**

Yearly wellness visit and many free preventive services for some seniors with Medicare.

**Holding Insurance Companies Accountable**

Insurers must justify any premium increase of 10% or more before the rate takes effect.

home care, supplies, and other things not covered by Part A. Some preventive services might also be covered. A monthly premium and yearly deductible are paid for Part B coverage. For more information, visit www.medicare.gov.

Congress created the diagnosis-related group (DRG) payment system in 1983 for 470 diagnostic categories to help control costs in the Medicare program, which previously had no reimbursement limits. All hospitals were paid the same fee for patients in the same diagnostic category regardless of length of stay and supply costs. The original DRG system has undergone modifications through the years, and today several DRG systems are in use that take into consideration all populations, complications, and comorbidities. Hospitals lose money if the patient’s costs exceed the DRG payment and make money if the costs are less than the payment.

Hospital-Acquired Conditions and Present-on-Admission Reporting

In 2008, the Centers for Medicare and Medicaid Services implemented a change for Medicare Severity DRG payments to acute inpatient prospective system hospitals. This policy is called the Hospital-Acquired Conditions (HAC) and Present on Admission (POA) Indicator Reporting. Box 3-1 shows the 11 categories of HACs (for updates, see www.cms.gov/Medicare/Medicare-Fee-for-Service-Payment/HospitalAcqCond/Hospital-Acquired_Conditions.html). At discharge, if certain conditions are not POA, hospitals do not receive additional reimbursement for those conditions. For example, if a patient was admitted with a stroke (primary diagnosis) and then developed a pressure ulcer that was not present on admission (secondary diagnosis) that could have been prevented, the hospital would receive reimbursement only for the primary diagnosis of stroke. The hospital would have to absorb the cost of care for the pressure ulcer.

With this requirement, nurses must carefully assess and document patient conditions that are POA to show that they did not occur during the hospitalization. Providing safe, quality care and educating patients to prevent complications, such as the need to do leg exercises, turn every 2 hours, or ambulate, are essential to prevent these conditions. Documenting interventions, education provided, and the patient’s refusal to participate (if applicable) are essential to help ensure reimbursement for secondary diagnoses.

Medicaid

The Medicaid payment system was also created in 1965 to provide health insurance as part of the Social Security Act for low-income or disabled persons younger than age 65 and their dependent children. Some low-income people older than age 65 can also qualify. Medicaid funding comes from federal, state, and local taxes. Benefits for Medicaid vary from state to state.

Managed Health Care

Health maintenance organizations (HMOs) deliver health care services to individuals who enroll in this type of prepaid group practice health program. The purpose of an HMO is to reduce overlapping services and provide quality and cost-effective care. Healthy patients require fewer services, so preventive care is promoted. Preferred provider organizations (PPOs) are networks of providers who offer care to plan members at set discounted rates. PPOs are designed to reduce

Box 3-1 Categories of Hospital-Acquired Conditions

The Centers for Medicare and Medicaid Services identified the following 11 categories of hospital-acquired conditions as those that increase health care costs or that could have been prevented by using evidence-based guidelines:

- Foreign Object Retained After Surgery
- Air Embolism
- Blood Incompatibility
- Stage III and IV Pressure Ulcers
- Falls and Trauma
  - Fractures
  - Dislocations
  - Intracranial Injuries
  - Crushing Injuries
  - Burns
  - Other Injuries
- Manifestations of Poor Glycemic Control
  - Diabetic Ketoacidosis
  - Nonketotic Hyperosmolar Coma
  - Hypoglycemic Coma
- Secondary Diabetes With Ketoacidosis
- Secondary Diabetes With Hyperosmolarity
- Catheter-Associated Urinary Tract Infection
- Vascular Catheter-Associated Infection
- Surgical Site Infection After:
  - Coronary Artery Bypass Graft—Mediastinitis
  - Bariatric Surgery for Obesity
  - Laparoscopic Gastric Bypass
  - Gastroenterostomy
  - Laparoscopic Gastric Restrictive Surgery
  - Certain Orthopedic Procedures
  - Spine
  - Neck
  - Shoulder
  - Elbow
  - Cardiac Implantable Electronic Device
- Deep Vein Thrombosis/Pulmonary Embolism
  - Total Knee Replacement
  - Hip Replacement
- Iatrogenic Pneumothorax With Venous Catheterization

costs to businesses that insure employees. Hospitals and physicians develop a contract with employers to provide services at a negotiated fee.

Managed care has led to fewer hospitalizations and shorter lengths of stay. Patients are using home health care for more complex needs. Case management is helping to ensure that the best patient outcome is achieved while controlling costs.

LEARNING TIP

To understand what the term `managed care means, reverse the words: care management.

NURSING AND THE HEALTH CARE TEAM

Nursing is an integral part of the health care network. Nurses work as licensed practical nurses (LPNs) or licensed vocational nurses (LVNs), registered nurses (RNs), or registered nurses with advanced education and practice skills, which includes certified registered nurse practitioners (CRNPs), clinical nurse specialists (CNSs), certified nurse midwives (CNMs), certified registered nurse anesthetists (CRNAs), and doctors of nursing practice (DNP). Certified nursing assistants (CNAs) are trained to assist nurses in providing health care.

Collaborative Care

Nurses work in collaboration with other members of the health care team:

• **Physicians** provide medical care to patients after graduating from a college of medicine (MD) or osteopathic medicine (DO).

• **Physician assistants** (PA-C [certified]), after graduating from a physician’s assistant program, work under the supervision of a physician and perform certain physician duties, such as history taking, physical examinations, and suturing of wounds.

• **Licensed pharmacists** complete 5 or 6 years of college and dispense medications from prescriptions, consult with physicians, and provide medication information to patients.

• **Social workers** usually have a master’s degree in social work (MSW), can be licensed clinical social workers (LCSW), and treat patients and their families with psychosocial issues.

• **Dietitians** provide nutrition information, analyze nutritional needs, and calculate special dietary needs.

• **Licensed physical therapists** complete a college physical therapy program and assist patients in reducing physical disability, bodily malfunction, movement dysfunction, and pain through evaluation, education, and treatment.

• **Physical therapy assistants**, whose educational requirements vary, might complete 2 years of education and be licensed and then work under the supervision of a physical therapist.

• **Occupational therapists** complete a bachelor’s or master’s program, can be registered (OTR), and assist patients in restoring self-care, work, and leisure skills that have been diminished as a result of developmental deficits or injury.

• **Speech and language pathologists** typically complete a master’s program. They provide direct clinical services to those with communication or swallowing problems.

• **Respiratory therapists** have a 2-year college degree, can be registered (RRT), and work with patients who have respiratory problems.

• **Respiratory therapy technicians** have 1 year of education, can be certified (CRTT), and work under the supervision of a respiratory therapist to provide respiratory care.

• **Health unit secretaries** manage clerical work.

• **Student nurses** are enrolled in a nursing program and work under the supervision of nursing faculty in the clinical setting.

LEADERSHIP IN NURSING PRACTICE

A leader seeks to influence, motivate, and enable others to achieve goals. *Leadership* skills are necessary for the LPN/LVN to effectively guide patient care and achieve patient care goals.

Effective leaders in a health care setting must be knowledgeable about management and supervisory processes. They must use critical thinking and be able to make decisions. They should be role models and an inspiration to others. A positive attitude and the use of humor are valuable assets of good leaders. Ultimately, leaders must earn the respect of their coworkers to be successful. To prepare for a leadership role, learning and applying the following principles of leadership, supervision, and management is helpful.

**Leadership Styles**

There are three traditional leadership styles: (1) autocratic, (2) democratic, and (3) laissez-faire. A fourth style called coaching is also used in health care settings.

**Autocratic (Authoritarian) Leadership**

An autocratic leader has a high degree of control. Almost no control is given to others. In **autocratic leadership**, the leader determines the goals and plans for achieving the goals. Others are instructed on what to do and are not asked to provide input. The group usually achieves high-quality outcomes under this style of leadership. This is an efficient leadership style for emergency situations when decisions must be made quickly, such as when evacuating a building or responding to a cardiac arrest.

**Democratic (Participative) Leadership**

A democratic leader has a moderate degree of control. Others are given some control and freedom. In **democratic leadership**, participation is encouraged in determining goals and plans for achieving the goals (Fig. 3.3). Decisions are made within the group. The leader assists the group by steering and teaching rather than dominating. The leader shares responsibility with
the group. The group usually achieves high-quality outcomes and is more creative under this style of leadership. This is an efficient leadership style for most situations. With this type of leadership, group members have greater satisfaction and are motivated to achieve goals because they are active participants.

**Laissez-Faire (Delegative) Leadership**

A laissez-faire leader exerts no control over the group, which is given complete freedom for decision making. With *laissez-faire leadership*, no one is responsible for determining goals and plans for achieving the goals. This can produce a feeling of chaos. Little is accomplished under this leadership style, and the quality of outcomes is often poor.

**Coaching Leadership**

By emphasizing active listening, clear communication, support, and accountability, coaching leaders work with others to develop problem-solving skills that facilitate critical thinking, prioritization, and effective communication. This leadership style helps direct-care employees feel more empowered, valued, and respected.

**Management Functions**

The five major components in the management process are (1) planning, (2) organizing, (3) directing, (4) coordinating, and (5) controlling.

**Planning**

In the first step of the management process, a plan must be developed to ensure that desired patient care outcomes are achieved. To formulate the plan, desired outcomes or problems are identified and data about them are collected. Alternatives or solutions are considered using the collected data and input from others. A decision is then made about the best option or course of action. The leader should ensure that the choice is realistic and can be implemented. Involving others in the planning and decision-making process from beginning to end can increase acceptance at the time of implementation.
Delegation is the act of empowering another person to act. Delegation occurs in a downward manner. RNs delegate to LPN/LVNs and unlicensed assistive personnel (UAP). LPN/LVNs, in certain circumstances, delegate to LPN/LVNs and UAPs (as discussed later). When delegation occurs, responsibility for care is transferred to the delegatee, but accountability for the care remains with the delegator. Guidelines for delegating can be found at www.ncsbn.org/1625.htm.

The LPN/LVN might function as a team leader or charge nurse mainly in the long-term care setting, requiring some use of delegation to UAPs. When the LPN/LVN acts as a team leader or charge nurse, an RN delegates the authority to provide supervision and delegation of tasks. Team leaders are responsible for the coordination and delivery of care to each of the patients assigned to the team. They assess the patients assigned to the team to plan appropriate care and contribute to the nursing care plan. Team leaders receive information from team members and communicate patients’ needs to appropriate individuals. Because team leaders guide patient care provided by the team, they must be knowledgeable about safety policies, patients’ rights, and the accountability of being a team leader.

All patients are entitled to quality care and treatment with dignity and respect. The team leader is accountable for all care provided by the team. Supervision involves initial direction for the task and then monitoring of the task and outcome at intervals. At the end of the team’s work shift, team leaders are responsible for transferring patient care to the oncoming team in a way that prevents communication breakdowns that result in patient harm. This hand-off communication is accomplished by reporting the patient’s condition, status, and needs to the oncoming team leader (Fig. 3.5). Institutional policy specifies whether the RN or LPN/LVN communicates the report.

Within the leadership role, the LPN/LVN must decide when delegation would most benefit the situation and the patient. All nurses must follow the state practice act and the scope of practice when making any decisions regarding delegation. Consult the charge nurse, team leader, and nurse practice act for your state when deciding if delegation is appropriate. Ultimately, you must ask several important questions to determine when delegation would best benefit the situation. These questions include the following:

- Does the state practice act allow for delegation in this situation?
- Does the person to whom I am delegating have the knowledge and education to perform this skill, and is it documented for me to make the decisions regarding delegation?
- Would it benefit the patient if I delegated this skill to the support person?

**Delegation Process**

Delegation is a complex process. In each case, take the following steps, which encompass the decision to delegate, what to delegate, and to whom delegation can be made:

1. Know your state practice act rules for delegation. The LPN/LVN scope of practice usually does not provide legal authority for an LPN/LVN to delegate. However, some state board rules allow LPN/LVNs to delegate tasks that are within the LPN/LVN's scope of practice as long as the RN has given the LPN/LVN authority to delegate the tasks.
2. Identify the skills of the person to whom you might delegate to determine if he or she has the knowledge and ability to carry out the task. When selecting a team member to delegate tasks to, consider if there is potential for harm to the patient during the task, whether it is a complex task that will require problem solving, how predictable the outcome is, and how much interaction with the patient is needed.
Match the skills and talents of the team member to the task being delegated. Remember, nursing judgment can never be delegated.

3. Use the National Council of State Boards of Nursing’s (1995) five rights of delegation. Following these guidelines provides a framework for your decision-making process and comfort in knowing you used them to make good choices:
   • Right task—is it appropriate to delegate?
   • Right circumstances—is this situation safe and appropriate for delegating?
   • Right person—is the delegatee the appropriate person for the task and this patient’s needs?
   • Right communication—is there clear understanding between you and the delegatee for terms used, communication, and reporting needs?
   • Right supervision—is it defined how and when direct supervision will occur?

Delegation requires trust. You should be comfortable with which tasks can be delegated and the team member to whom you are delegating the tasks. Also, it is important to know and understand each other’s methods of communicating so that miscommunications do not occur.

When you first begin your career, the process of delegating can seem difficult. As with any skill, it takes practice to feel confident in carrying out the process.

EDUCATIONAL AND CAREER OPPORTUNITIES FOR LPN/LVNs

LPN/LVNPs might seek additional education. Many schools provide for an accelerated educational tract for LPN/LVNs seeking to become RNs. Advanced educational opportunities include a master’s degree or a doctoral degree. Check with colleges/universities to see which program would best meet your needs for continuing your education. Post licensure certification for the LPN in pharmacology, long-term care, or IV therapy is offered by National Association for Practical Nurse Education and Service (NAPNES) and National Federation for Licensed Practical Nurses (NFLPN).

Because of the health care needs of the increasing older adult population and an increased need overall for health care services, the need for LPN/LVNs is expected to grow 25% between 2012 to 2022, which is faster than the average for other occupations (Bureau of Labor Statistics, 2014–15). LPN/LVNs work in child day-care centers, clinics, corrections, home care, hospitals, long-term care, HCP offices, dentist offices, and schools, among other health care settings. Employment of LPN/LVNs is declining in hospitals, but it is growing in settings outside of hospitals.

Correctional Nursing

A growing clinical setting for the LPN to work in is correctional nursing. Local, regional, and state regional facilities are interested in hiring LPNs to care for inmates and handle worksite wellness programs for correctional officers and other staff. Key in this practice area is the ability for the nurse to appropriately apply professional theory, practice, and ethics within the correctional setting. Correctional nurses must possess good physical and mental health and retain sufficient stamina, agility, and visual/auditory acuity necessary to perform all duties associated with LPN practice. In this setting, the LPN must be able to:

- Independently implement the nursing process with inmates/residents in following HCP orders regarding diet, medication and treatments
- Utilize knowledge of current medications (actions, interactions, uses, and side effects)
- Utilize knowledge of medical, therapeutic, and psychiatric nursing interventions
- Appropriately apply quality standards, procedures, and protocols as directed
- Be knowledgeable about and sensitive to cultural and socioeconomic differences among the populace as they relate to health and behaviors
- Demonstrate an interpersonal skill set that includes high quality oral and written communication skills to facilitate cooperation, pride, trust, and commitment to quality health/medical team communication
- Maintain institutional records and provide required institutional reports
- Consistently demonstrate medical team professionalism in assessing and providing inmate health care delivery as directed by the HCP
- Interview, listen, and provide empathetic assistance to inmates in meeting their needs by carrying out prescribed treatments within the LPN scope of practice
- Respond to emergencies as a part of the health care team
- Appropriately respond to and seek supervision as needed
- Observe, monitor, analyze, and evaluate appropriate nursing care, teaching, and treatment
- Provide precertification for and coordination of inmates admitted to and discharged from acute care facilities by contributing to and implementing their nursing care plans and routine health tests
- Work effectively and efficiently when exposed to difficult or challenging working conditions/situations related to incarcerated patients

ETHICS AND VALUES

Ethics is a code of values which guide our choices and actions and determine the purpose and course of our lives.

Ayn Rand, Russian-Born American Novelist and Philosopher (1905–1982)

The study and practice of ethics is grounded in philosophy and dates back to the time of Hippocrates. Ethics is a systematic approach not only to understanding an ethical dilemma but also to examining the best outcome for each situation (Butts & Rich, 2013). Bioethics is a branch of ethics that studies moral values in the biomedical sciences and has come to be most closely associated with health care. Today more
than ever, nurses are confronted with new technological advances mixed in with the challenges of a changing economic climate. These variables often create ethical dilemmas in health care.

Morals or morality are also related to ethics, and although the terms ethics and morals are often used interchangeably, morals refers more specifically to personally derived values, beliefs, and behaviors we tend to think of as “right and wrong” or “good and bad” (Butts & Rich, 2013).

Values are unwritten standards, ideals, or concepts that give meaning to a person’s life and that often serve as a guide for making decisions and setting priorities in daily life. Although values are commonly derived from societal norms, religion, and family traditions, they can change when a person experiences life-changing events. Value conflicts often occur in everyday life, and people make decisions based on their values. For example, a nurse who values both her career and her family might be forced to decide between going to work or staying home with a sick child.

Values exist on many levels. Individuals have personal values that govern their lives and actions. Many groups and organizations have values that represent the group as a whole but may or may not be identical to personal values. When a person becomes a member of a group or organization, he or she agrees to accept the values of the group. Examples of groups include clubs, churches, political parties, and professions. Society as a whole has values. As a member of a society or country, an individual accepts the values of that culture. The values of a profession are usually outlined in a code of ethics. This code is a comprehensive set of guidelines that outlines the behavioral expectations for the profession.

Ethical issues surround us throughout our lifetime. Bioethical issues are particularly prevalent in our professional lives for several reasons. To begin with, advances in technology and new treatment options both of fer prolonging or saving life. However, in doing so, questions arise related to medical futility such as: Who should receive treatment? How long should treatment continue? Should a patient receive a treatment because it is available, or because it will be effective? How many health care resources should be utilized for the treatment of terminal illnesses? Does quantity or length of life matter more than quality of life? Therefore, it becomes both difficult and important to decide how and when resources will be allocated.

Not all bioethical issues make headline news. In fact, many ethical dilemmas are regular occurrences in the clinical setting. Research shows that many ethical dilemmas arise related to situations such as inadequate staffing protection of patients’ rights, unethical practices of HCPs, end-of-life decision making, and breaches in confidentiality (Ulrich et al, 2010). Nurses are involved in decision making every day based on the traditional ethical principles of autonomy beneficence, maleficence, and justice. Have you experienced any of these examples? You are asked to consistently work on a unit that is understaffed. Your charge nurse asks you to “sign her in for the shift” on a regular basis. A patient asks you to keep his prognosis from his spouse. You overhear a coworker discussing a patient’s status on the telephone, but you do not know who is on the line. Each of these examples prompts questions such as the following: What should be done? What ethical principles are involved? Whose wishes should be honored?

An ethical dilemma is a situation in which a person must choose between two options that will affect the outcome of the case. Although each option can be justified as “good,” both have pros and cons. Therefore, when one option is selected or implemented, it creates uncertainty in the outcome of the case (Butts & Rich, 2013).

Decision making in the acute care setting is a complex process involving many members of the health care team. As a result of carrying out orders, nurses must handle consequences that arise from clinical problems. In addition, there is no one-size-fits-all solution for ethical problems. Even if dilemmas share a common thread, each has individual influences that make it unique.

Potential solutions can appear to be equally good or worse, equally risky: a promise cannot be kept; information
cannot remain confidential; DNR (do not resuscitate) orders might not be acceptable for some people. Not all patients should receive CPR, even those who are young. When patients are conscious, their choices are usually respected, but on occasion, even that premise can be difficult to apply. Often, groups of individuals must work together to resolve a conflict if there is disagreement between an HCP and families, nurses and other HCPs, or among family members. Nurses can experience moral distress as a result of being an integral part of this team. Moral distress can be defined as distress experienced when knowing the right thing to do but being unable to carry it out because of institutional constraints (Jameton, 1984). More recently, moral distress has been associated with job satisfaction and is one of the reasons that nurses leave nursing (de Veer et al., 2013). In response to increasing ethical and moral conflicts in the clinical setting, many hospitals and facilities have created an ethics committee that helps address especially difficult cases. The multidisciplinary committee might include nurses, other HCPs such as therapists, social workers, and an ethicist.

A basic mastery of several elements enhances your ability to perform competently when bioethical issues arise and decision making is the focus. Understanding the ethical component of your nursing role is the first step. Discovering how your personal value set influences your nursing practice is another. Acquiring knowledge about relevant ethical material is also essential. An ethical decision-making process is a useful tool for examining ethical dilemmas. Together these elements provide a foundation from which you can begin to explore the meaning of bioethics in nursing practice today. For more information about bioethics, visit the Center for Bioethics and Human Dignity at www.cbhd.org.

**Ethical Obligations and Nursing**

As a nurse, you are an invaluable member of the health care team, contributing to patient care according to your educational preparation and assigned responsibilities. You are guided by the law and the standards set forth by the profession. A professional code of ethics provides a framework. In addition to practicing within the law, nurses have ethical obligations related to the law. First, if the law is considered unethical or has serious limitations, a basic moral obligation of the nurse is to make an effort to change that law. This might be done individually or through political activism guided by professional organizations. Becoming involved in professional organization is one way to help change the laws that govern health care and nursing.

**Nursing Code of Ethics**

Some of the major ethical obligations of nursing practice are addressed in a nursing code of ethics. A code of ethics should provide guidance for appropriate decision making based on current laws and professional standards. A code of ethics not only provides a base for professional self-evaluation and reflection but also acts as a tool by which the public can hold the profession accountable. As a professional guide for ethical practice, NFLPN has practice standards that include ethical practice and conduct. See www.nflpn.org/practice-standards4web.pdf. NAPNES also has standards of practice for LP/VNs at www.napnes.org.

A code does not dictate a particular action, nor is it a legal document, although the code should not be in conflict with the law. The code is not enforced by any organization, and no punishment exists if a nurse fails to adhere to it. A code must be interpreted because it usually contains broad statements, but it does serve as a general guideline for professional ethical issues. Ethical codes are updated to reflect current practice, responsibilities, and obligations set forth by the profession.

**Building Blocks of Ethics**

The discipline of ethics, especially health care ethics, provides us with useful tools and knowledge that can assist us when we encounter difficult situations. An understanding of basic concepts, presented here in the form of ethical principles and ethical theories, helps specifically target the ethical components of the problem. Principles and theories offer frameworks for ethical problem solving. However, knowledge about ethics cannot in itself provide all of the answers to a problem or dilemma. What such knowledge does do is assist us in focusing on the ethical aspects of each case and possibly prevents escalating arguments about issues not related to the ethics of the case.

**Ethical Principles**

Ethical principles derive from moral theory and have two purposes. The first is to provide some framework for society’s moral conduct. The second is to help us take consistent positions and approaches to moral dilemmas. Ethical principles can be found in many professional codes of conduct and are key components of ethical decision making. The ethical principles widely used when examining bioethical and health care dilemmas include autonomy, beneficence, nonmaleficence, fidelity, veracity, and justice. Given the prominence of these ethical principles in the bioethical literature, a basic understanding of them is necessary.

**AUTONOMY.** According to ethicists (and behaviorists, social scientists, and psychologists), what makes human beings different from nonhumans is that people have dignity based on their ability to choose freely what they will do with their lives. Autonomy is the right of self-determination, independence, and freedom founded on the notion that humans have value, worth, and moral dignity. Autonomy in health care applies to all people capable of and competent in making health care decisions for themselves. HCPs do not need to agree with another person’s decisions, but must respect the autonomy of the person making the choice. Paternalism occurs when an HCP tries to prevent patients from making autonomous decisions or decides what is best for patients without regard for their preferences. Autonomy also encompasses the professional’s self-determination and freedom.
There are limitations to autonomy. Typically, these limitations arise when a person’s autonomy interferes with the rights, health, or well-being of self or others. For example, patients generally have an autonomous right to make decisions regarding their care and level of independence. This autonomous right is guaranteed by federal legislation known as the Patient Self-Determination Act, which can be found at www.nrc-pad.org/images/stories/PDFs/fedaddirectives2a.pdf. However, if a person is no longer capable of self-care upon discharge, a request to live independently will not be granted. A person unable to adequately care for himself cannot live alone at the expense of his health and well-being. Thus the principle of autonomy cannot be upheld.

**Beneficence.** The principle of beneficence proposes that actions taken and treatments provided will benefit a person and promote welfare (Butts & Rich, 2013). The provision of good care not only means the provision of technologically competent care but also care that respects the patient’s beliefs, feelings, and wishes, as well as those of their family and significant others. A common problem encountered when applying this principle is deciding what is good for someone else.

**Nonmaleficence.** Nonmaleficence is one of the oldest obligations in health care, dating back to the Hippocratic oath (400 B.C.). Nonmaleficence is the obligations to “do no harm” (Butts & Rich, 2013). It is common to hear beneficence and maleficence talked about as being “two sides of the same coin.”

HCPs are required to do no harm to their patients either intentionally or unintentionally. In current health care practice, the principle of nonmaleficence may be intentionally violated to produce a greater good in the patient’s long-term treatment. For example, a patient might undergo a painful and debilitating or disfiguring surgery to remove a cancerous growth, thereby avoiding death and prolonging life.

By extension, the principle of nonmaleficence also requires a nurse to protect from harm those who are considered vulnerable. Vulnerable groups include children, older adults, and those who are mentally incompetent, unconscious, or too weak or debilitated to protect themselves.

**Fidelity.** Fidelity is the obligation to be faithful to commitments made to self and others. In health care, fidelity includes faithfulness or loyalty to agreements and responsibilities accepted as part of the practice of nursing. It also means not promising a patient something that one cannot deliver or control. Fidelity is the main support for the concept of accountability, although conflicts in fidelity might arise because of obligations owed to different individuals or groups. For example, nurses have an obligation of fidelity to the patients they care for to provide the highest quality care possible, as well as an obligation of fidelity to their employing institution to follow its rules and policies. Nurses can have an ethical dilemma when a hospital’s policy on staffing creates a situation that does not allow nurses to provide the quality of care they feel is needed.

Maintaining a patient’s privacy and confidentiality is related to fidelity (Fig. 3.6). Privacy and confidentiality may or may not be explicit promises. Nurses are obligated to discuss the patient only under circumstances in which it is necessary to deliver high-quality holistic health care, such as:

- When given specific instructions to do so by the patient
- When there is the grave possibility of harm to either the patient or others
- When legally mandated to do so

Maintaining confidentiality also applies to the necessary communication of information through the posting of unit censuses and various schedules for tests, procedures, or special examinations (operating room, physical therapy, radiology), storage and access of patient information in computers, and the transmission of patient information via fax machines. Many people other than direct caregivers have legitimate access to a patient’s chart: faculty members in the course of making student assignments, accrediting agencies, risk managers, quality assurance personnel, insurance companies, and researchers. Each is obligated to maintain patient confidentiality to the extent that concealing information:

- Does not compromise mandated reports (communicable diseases or gunshot wounds).
- Considers various releases already granted by the patient (such as when insurance information was obtained).
- Ensures gathering data in the aggregate without identifying specific patients (research or institutional statistics).

Other forms of necessary communication include shift-change reporting and case conferences. Care must be taken to hold these information-sharing events in settings where the discussion remains private.

**FIGURE 3.6** Maintaining privacy is a patient right and conveys caring to the patient.
VERACITY. Veracity is the virtue of truthfulness. Within health care, it requires HCPs, whenever possible, to tell the truth and not intentionally deceive or mislead patients. As with other rights and obligations, there are limitations to this virtue. The primary limitation occurs when telling patients the truth would seriously harm their ability to reco ver or when the truth can produce greater illness. This is known as therapeutic privilege and is exercised by HCPs in cases when (1) they are trying to protect patients from heartbreaking news, as in the initial stages of treatment; (2) they do not know the facts, making it better not to answer rather than instill false hope; and (3) the state what is true rather than state what is not true (Butts & Rich, 2013). An example of this is when there is a new or experimental treatment. HCPs can say that in certain clinical trials, patients benefitted in specific ways, but they might not be able to cite all of the possible side effects because the treatment has not yet been widely used.

Another difficult situation can be created in relation to diagnostic information. Although giving diagnostic information is the responsibility of the HCP or RN, LPNs/LVNs sometimes find themselves in situations in which they must deal with patients’ questions. If LPNs/LVNs feel uncomfortable about reinforcing explanations given by the HCP or the RN, they might avoid answering patients’ questions directly. However, patients do have a right to know this information. The LPN should inform the HCP or RN of the patient’s request for information, and agency policy on patient information sharing should be followed.

JUSTICE. Justice is based on fairness and equality (Butts & Rich, 2013). Concerns for justice can focus on how we treat individuals and groups in society (psychologically, socially, legally, and politically), and how we equitably distribute material resources such as health care (distributive justice) and burdens (taxes) and the appropriate compensation to those who have been harmed. When a patient makes an appointment for 0900 at an outpatient clinic, the patient expects to be seen by the HCP at the designated time unless an emergency occurs. Unequal treatment would result if a walk-in patient who has no pressing problem is seen by the HCP in place of the patient with the 0900 appointment, forcing subsequent appointments to be delayed. Distribution of material resources can be complex because it involves not only benefits (what we receive), but also burdens (what we may be taxed for but then do not receive). Burdens are not just monetary but also include such factors as the unequal participation of individuals in medical research and the sacrifices family members make when caring for individuals with disabilities in the home.

USE OF PRINCIPLES. One of the most serious limitations of these principles is the lack of any built-in priority when applying them to an ethical dilemma. Autonomy is not automatically prioritized over justice or beneficence over nonmaleficence. However, these principles are helpful in categorizing various preferences and positions when examining a dilemma to clarify positions within it. Working with principles moves the discussion to a focus on ethics rather than on a particular personal viewpoint or feeling. Such a strategy can also avoid a power struggle between those who simply want to win the argument.

Here is an example of an ethical dilemma. A nurse attempts to support a patient’s refusal of surgery, whereas the surgeon claims that the patient must have surgery to avoid losing a foot. When you shift your thinking to realize that the nurse is arguing the case from the perspective of the patient’s autonomy (self-determination) and the surgeon’s actions are motivated by beneficence (to act in a way that benefits the patient), the discussion becomes one based on conflicting principles, rather than conflict between individuals. Consequently, the discussion can focus on autonomy and beneficence and their respective rationales. This strategy does not resolve the dilemma but makes it less personal and forces participants to develop sound, ethical rationales for their solution.

Ethical Theories

Ethical theories are concepts that are more complete than principles for analyzing ethical dilemmas. Theories are used to explain variables, guide inquiry, and provide a foundation with which to conduct decision making. A brief description of two of the major bioethics theories—utilitarianism and deontology—is provided here. Other theoretical approaches to ethical decision making exist, and theories are often combined to address ethical dilemmas. This section also explores the relationship of theology or religion to bioethics.

UTILITARIANISM. Utilitarian theory is grounded in the premise that actions are judged right or wrong based purely on their consequences, and therefore, outcomes are the most important elements to consider when making decisions. Right actions are morally preferred if they produce more happiness or greater benefits than unhappiness or burdens, and in utilitarianism, each person’s happiness is equally important. This approach can be used by institutions and organizations under the guise of cost–benefit ratios. A hospital responsible for the care for hundreds of patients is not as concerned with the individual patient who unfortunately is caught in the bureaucracy of its functioning. This is not to say that all institutions operate on this theory at all times, but, in general, rules, policies, and procedures are developed with the majority in mind.

There are several major criticisms of the utilitarian theory. One is that an individual is often sacrificed for the good of the majority (often seen in wartime). The second is that it can be difficult to predict outcomes, especially when human nature is involved.

DEONTOLOGY. Deontology is a philosophical theory requiring human actions and attitudes to be based on duty, and the moral worth of an action (the result) should not be judged only in terms of its consequences. For example, HCPs might operate by a rule indicating that a moral person never lies. No matter how much the truth might hurt, the truth is revealed. Another rule might be to never use people as a means to an end. Translated, this means that regardless of the benefits, individuals cannot be forced to participate in medical research studies to benefit others. An individual’s right to voluntarily participate in research must be respected. Research does not have to benefit the individual participant as long as
this is understood by the individual. However, the individual cannot be used simply to meet the investigator’s needs. Acting morally only because one has a duty to do so, without any consideration of the outcome, is a serious limitation of this theory.

THEOLOGICAL PERSPECTIVES. Theological perspectives include the many religious traditions represented in our culture. Religious teachings are key concepts for ethical decision making for some people. In fact, many consider these teachings a divine source of values and morals. Jehovah’s Witnesses’ rejection of blood transfusions is a common example of how religious beliefs affect health care decision making. This religious group has collected a large amount of information about blood substitutes and alternative therapies. Leaders of Jehovah’s Witnesses are prepared to provide education for HCPs about their beliefs and acceptable interventions.

In another area, a number of religious traditions oppose abortion, which affects both HCPs and patients. Euthanasia is another issue addressed by numerous organized religious groups, which in turn can affect how patients make decisions regarding end-of-life issues. One of the difficulties with religious traditions is that it is not simply the official church teaching that is involved but also the individual member’s interpretation of that teaching. Assessment of the importance of this dimension of the patient’s life is important in an ethical analysis.

Ethical Decision Making

A variety of models and frameworks are available for ethical decision making. The steps listed in this section are a combination of several ideas that have been suggested. In its simplest form, ethical decision making is an informed logical problem-solving process. Similar to the nursing process, as discussed in Chapter 1, the steps described in this section take the user through a set of strategies that assist in approaching a problem in an organized and systematic manner. Nurses applying the steps of the nursing process use critical thinking skills to be as logical and objective as possible. Ethical decision making is a similar process. The goal is to have a balanced perspective that respects emotions but does not let them overshadow the process or the outcome.

Addressing ethical dilemmas is not a simple or easy process. However, the final decision can be more acceptable if the nurse feels the situation was thoroughly examined and all viable options weighed before the decision was made. To illustrate the process, a sample case is examined using each step.

Sample Ethical Dilemma

The Smith family was in an automobile accident out of state. The family was on their way home from vacation. Mrs. Smith is in critical condition. Mr. Smith was pronounced dead in the emergency department, and their 12-year-old daughter, Melissa, is in critical condition. Mrs. Smith is still able to speak and asks you, the nurse, how her husband and daughter are doing. What should you do?

STEP 1: IDENTIFY THE ETHICAL DILEMMA. The initial step is to identify the ethical dilemma. What makes it a true dilemma? Separating the ethical and nonethical aspects facilitates the decision-making process. A conflict can arise because of gaps in communication rather than a conflict of ethical principles. Ethical dilemmas are different from clinical problems that have clear interventions and rationales.

Our sample case is an ethical dilemma because there is no obvious right answer. Do you tell the mother that her spouse is dead and her child is critically injured?

STEP 2: IDENTIFY THE STAKEHOLDERS AND THEIR VALUES. The values, beliefs, and traditions of all participants are important because they will all influence the decision-making process. The patient is at the center of the process. Therefore, the patient’s autonomy is important to the steps of the process. An advance directive or a living will can often help guide the decision-making process when the patient no longer has autonomy (the ability to express his or her own wishes). Even if there is a preexisting advance directive, it might not match the wishes of the family for clinical decision making.

In our sample case, who are the stakeholders? Obviously, family members are all stakeholders, as well as the health care team of nurses, HCPs, therapists, and others. The patient is the patient and at the center of the process. We will keep in mind that the daughter is also a patient, but her role in this situation is not the ethical dilemma. What is the autonomy of the patient? At present, the patient is not fully autonomous because she suffered head trauma.

STEP 3: GATHER AND VERIFY THE INFORMATION. All facets of the dilemma need to be examined. Besides knowing who is involved, the context of the problem must be fully explored. How did the situation arise? Are there objective data to support various parts of the decision-making process? For example, determining competency can be an involved and frustrating process, especially when there are competing parties involved (such as a family disagreement about the competency of a parent). However, objective data such as a mental evaluation can support this fact and ease family disagreements. Both the medical record and the HCP can provide clinically relevant data. In addition, health care records from previous hospitalizations and from other institutions might also be needed. The law, facility policies and procedures, and available resources also have an impact on the overall context of the problem. Therefore, it is necessary to be comprehensive in examining all of these areas.

In our sample case, what do we know? The objective data tell us the following: (1) The spouse is dead; (2) the daughter who is 12 years old, is in critical condition; (3) the family is from out of state; and (4) on assessment, we find that the mother experienced head trauma, and although she is asking about her spouse and daughter, her vital signs are unstable and her condition is also critical. So in considering the objective information, we must also gather more information. What comes to mind? Does Mrs. Smith or her daughter have any significant health history or take medications that the health care team should know about? What are the policies regarding contacting family in such an emergency? What resources or departments need to be called to assist in this case?
STEP 4: EXAMINE POSSIBLE ACTIONS AND THE CONSEQUENCES OF EACH ACTION. Bringing perspective to an ethical dilemma requires the development of a comprehensive set of all possible actions. In turn, each of the proposed actions should have identified consequences, both positive and negative. This makes the process more transparent and allows anyone to analyze each action by weighing the risks and benefits of implementing that action.

In our sample case, what are all of the possible actions or alternatives to resolve the dilemma? If you consider the extremes, the choices appear clear: You either tell Mrs. Smith about her husband and child, or you do not. If you tell Mrs. Smith that her husband is dead and her child is in critical condition, what are the consequences, both positive and negative? These are considered the extremes in the case. But there are other options. For example, we could calm Mrs. Smith by saying that her husband and daughter are both still being evaluated, or we could call a chaplain to assist the staff in telling her the truth. Even if partial truths seem unacceptable at first glance, they should be added to the list of possible actions.

So, as you can see, each proposed action should have corresponding consequences that allow those involved to ultimately choose the best action to be implemented. Can you think of any more actions appropriate for this scenario? What are the consequences for these actions?

STEP 5: DETERMINE THE ETHICAL FOUNDATION FOR EACH ACTION. Each action should be based on ethical values, principles, or theories. In addition, the code of ethics can lend support as an ethical rationale. One strategy that is proposed for an incompetent or unconscious patient is the standard of best interest. This standard involves determination of the best outcome for the patient, given the information known about the patient and the context of the situation. Typically, family members together with HCPs make this determination. Ideally, the decision is made in an objective manner, setting aside any special interests of the family or HCPs.

In our sample case, if we revisit the actions proposed in the previous section, we can see that telling the truth supports veracity but also supports beneficence. In contrast, by not telling the truth, we violate the principle of veracity but uphold beneficence. Lastly, if we entertain the idea of only telling part of the truth, we violate the principle of veracity but uphold beneficence. We realize that by telling the whole truth, Mrs. Smith’s condition can worsen from the stress of the situation.

STEP 6: DETERMINE THE BEST ACTION WITH THE STRONGEST ETHICAL SUPPORT. Each action is judged based on its risks, benefits, and supporting rationale. The actions are then ranked in priority order. Strong ethical support for the first priority is required, as well as a reasonable potential for the action to be implemented.

In our sample case, what do you think is the best outcome? Everyone needs to examine the actions and their respective consequences and supporting ethical principles before making a final decision.

Utilitarians and deontologists might disagree about the important principles in decision making. However, do not assume that different theoretical positions cannot reach a mutually agreeable decision. Although their rationales for the decision may differ, the final solutions each proposes may be identical.

STEP 7: IMPLEMENT THE ACTION. The selected action needs to be implemented in a logical way. Responsibilities for carrying out the plan can be assigned, especially if there are multiple steps in the process. In addition, a well-implemented plan can ensure that the plan is fully operationalized and also increases the potential for success.

In our sample case, each person must implement a plan based on the stakeholders, the chosen action, and the underlying ethical principles. How would you implement your action? What resources would you need? Which members of the health care team would you work with?

STEP 8: EVALUATE THE OUTCOME. The evaluative process is most effective when the details of the care are still fresh. The resolution of an ethical dilemma, whether it has been successful or not, provides us with knowledge and experience to address the next ethical dilemma. Although each dilemma is unique in many ways, similarities between cases can provide insight into the best way to approach the decision-making process when a comparable case arises.

In our sample case, the outcome can be evaluated only after an action is implemented.

CRITICAL THINKING

Ethical Decisions

Identify a health care–related ethical dilemma you have encountered as a student. How did you solve the dilemma? What expert resources did you use?

Apply the ethical decision-making model to your ethical dilemma. How are your decision-making process and proposed actions different when using the model?

LEGAL CONCEPTS

To promote harmony, safety, and productivity as members of a society, we create rules. The rules of society can be informal or formal. An informal social rule, for example, is opening a door for someone when entering a building. Criminal statutes (law) are examples of formal rules of society. These social rules, or codes, promote our individual well-being. It would be unsafe to live in a community that existed without rules, and all societies require minimum standards of conduct for their members. Laws exist to define individuals’ duties to themselves, their neighbors, and their government.
Regulation of Nursing Practice

Nursing is a licensed health care profession that is regulated by individual states. Nurses must be licensed by their state to practice nursing. The rationale for state licensure is to improve the quality of health care services and to protect the health, safety, and well-being of the general public residing in that state. As such, state governments have licensing boards that establish the requirements for nurses entering the nursing profession. Also, these state licensing boards are charged with defining the scope of practice for nurses already licensed by the state. State laws that regulate nursing practice can be found within an individual state’s nurse practice act, as well as within regulations created by a state’s licensing agency.

A state’s nurse practice laws, including all attendant nursing regulations, establish the parameters of nursing practice. Nurses must practice within these parameters to maintain a license in good standing. These laws are commonly referred to as administrative laws. Violating these laws can be the basis for disciplinary actions by a state licensing body. And a nurse’s failure to adhere to the regulatory mandates of a state’s licensing body can result in the loss of his or her privilege to practice nursing in that state. Unprofessional conduct and conviction of a crime are two circumstances that can give rise to a nurse licensing body finding cause to revoke a nurse’s license to practice.

Health Insurance Portability and Accountability Act of 1996

Since 1996, the federal government has protected the distribution of personal health information (PHI). All health care workers including students are required to follow the requirements established by the Health Insurance Portability and Accountability Act of 1996 (HIPAA). This act creates both civil and criminal liability for HCPs who wrongfully disclose a patient’s health information. Developed by the U.S. Department of Health and Human Services, this privacy rule was the first of its kind to establish federal protection of PHI.

HCPs must be sensitive to the legalities concerning the dissemination of PHI, because HIPAA establishes stringent guidelines. Depending on the seriousness of the violation of HIPAA standards, an individual can be fined and/or sentenced to up to 10 years in prison, be personally sued, and face employer’s disciplinary action including termination. Stay informed by reviewing your employer’s HIPAA compliance policies and then adhere to them. For more information on HIPAA and its impact on health care information and HCPs, see [www.hhs.gov/ocr/hipaa](http://www.hhs.gov/ocr/hipaa).

Social Media and HIPAA

With the explosion of social media use, health care or organizations have heightened their oversight of PHI to protect against its improper dissemination. HIPAA is a serious law with serious consequences. It can be violated in a variety of ways by health care employers such as accessing patient medical records without authorization or a need to know, taking photos in patient settings on personal devices, posting patient information including images such as photos or x-rays on social media sites, and making personal postings on a social media site in which identifiable patient information is included. Responsible use of social media to avoid violation of HIPAA is essential for all members of the health care team.

It is safest to keep one’s professional and personal life separate when using social media. Discussing your nursing shift on Facebook is not a safe practice, even if you do not use patient names. It can be a violation of HIPAA. Also be aware that employers might review social media sites as part of the hiring process. See [www.ncsbn.org/Social_media_guidelines.pdf](http://www.ncsbn.org/Social_media_guidelines.pdf) for more information and examples on safely using social media as a professional. Patient confidentiality and privacy in all settings must always be maintained.

Nursing Liability and the Law

Laws establish liability, or responsibility, for wrongful actions. Following the law is a major part of the practice of nursing. Administrative laws establish the licensing authority of the state to create, license, and regulate the practice of nursing. Criminal law regulates behaviors for citizens within this country. Civil law provides the rules by which individuals seek to protect their personal and property rights.

Criminal and Civil Law

Criminal laws establish rules for social behavior and define the punishment for breaking those rules. Violation of criminal laws typically results in imprisonment and/or monetary fines. Everyone, regardless of occupation, is required to obey a government’s criminal laws.

Criminal law differs from civil law in two ways: (1) in criminal law, society, as a whole, is the party wronged by the criminal act, and (2) violating a criminal law can result in imprisonment. Breaking a criminal law can result in both criminal punishment and civil liability. For example, an intoxicated driver can go to jail for a crime, but that same driver can also be held liable in a civil action for any personal injury to others (an individual or multiple parties, not society) that resulted from the criminal behavior. Examples of criminal acts are assault, battery, rape, murder, and larceny. Civil law, generally, concerns disputes among individuals, including companies. Actions that result in violations of civil law typically do not give rise to criminal behavior; however, liability for violating civil laws can still result in stiff penalties meant to deter future violations.

For HCPs, civil liability is a constant concern. Most civil claims against HCPs arise from patient care. Civil law allows patients and families to monetarily recover for injuries received at the hands of a HCP. Patients and families must show causation between the HCP’s action and the patient’s injury to recover. Showing causation requires an injured party to demonstrate that an HCP’s action or failure to act—an omission—directly and proximately caused the underlying injury. An injury can be physical, emotional, and financial in nature. Lawsuits involving personal injury are called torts.

A civil liability suit begins with the filing of a complaint with a court. Court rules require that a copy of the complaint be given, or served, on a defendant by the plaintiff. The
person claiming a civil cause of action and injury is the plaintiff, and the person alleged to have caused the injury is the defendant. A summons (notice to defendant(s) of the lawsuit) should be attached to the complaint. The complaint describes the claim being made by the plaintiff, and the summons instructs the defendant(s) regarding the time in which to answer the complaint, usually 20 to 30 days.

Nurses served with a work-related summons should notify their employers. Summons and complaints are serious. A nurse who receives a summons must ensure that the summons is answered. If the employer does not answer the summons, the nurse must seek legal counsel to answer the summons within the specified time. Failure to answer the summons and complaint can result in a default judgment (an acknowledgment of liability).

The institution that employs the worker can also be liable for the acts or omissions of its employed HCP. This theory of liability is called respondeat superior. Here, it is important for employees to understand that their work can result in civil liability for their employers, too.

Malpractice is defined as a breach of the duty that arises from the practitioner–patient relationship. This term includes liability arising from either intentional or unintentional acts (torts), or both. Intentional torts concern lawsuits wherein the defendant is accused of intentionally injuring the plaintiff (Table 3.2). On the other hand, unintentional torts concern negligence. Negligence occurs when one’s failure to exercise due care results in an injury to another. Societal rules require that we exercise due care when acting in the presence of others. The failure to exercise due care is referred to as a breach of duty. Professionals must uphold a duty of care when interacting with their patients. Malpractice occurs when a HCP fails to uphold this underlying duty, causing injury to a patient as a result. Malpractice is professional negligence (Box 3-2). All HCPs, including LPN/LVN, are responsible for the actions they undertake at the bedside, no matter whether those actions are intentional or negligent.

### Limitation of Liability

All professions are concerned with the limitation of liability, or limiting the amount of monetary damages that a defendant must pay to an injured plaintiff. Ways to limit liability include ensuring patient rights, accurately documenting in the patient record, following institutional policies, acquiring individual malpractice or liability insurance, pursuing continuing education, and practicing in accordance with the current standards of the nursing profession. Some states have enacted tort reform legislation. Much of this legislation is directed at limiting liability for HCPs and provider institutions. Examples of this reform legislation include things such as limitations on the monetary value that can be awarded to a plaintiff.

### Patient Rights

All patients are entitled to quality care and to be treated with dignity and respect. To provide quality care and limit liability, understand and provide the rights your patient is entitled to and question directions that are controversial, given verbally, concern situations of high liability, or involve a discrepancy between the direction and standard policy. Rights are defined as something due to an individual according to just claims, legal guarantees, or moral and ethical principles. Welfare rights, also called legal rights, are rights that are based on a legal entitlement to some good or benefit. These rights are guaranteed by laws such as the Bill of Rights and, if violated, can come under the powers of the legal system. For example,

<table>

</tbody>
</table>

### Box 3-2 Components Needed for a Finding of Negligence

- A duty of care owed to patients
- A breach of the duty of care
- Injury and damages occurring from the breach (of the duty of care)
- Causation (a showing that the injury was caused directly and proximately by breaching the duty of care). Must have both:
  - Direct cause = The injury resulted from the breach of duty.
  - Proximate cause = The injury was a foreseeable consequence of the breach of duty.
citizens of the United States have a right to equal access to employment regardless of race, sex, or religion. The type of treatment and care a patient has the right to expect is outlined in the Patient Care Partnership (www.aha.org/content/00-10/pcp_english_030730.pdf). Stay informed about the status of patient rights’ legislation because you will be expected to follow it. Knocking before entering a patient’s room and introducing oneself to the patient are examples of a patient’s rights.

The Importance of Documentation

Documentation is a legal record of your actions. Document nursing actions based on orders given, including the name and title of the person who gave the direction, especially if the directive was verbal. Documentation must be clear, honest, and accurate. Always document in the manner that is generally accepted by the nursing profession and your institution. Review and use your agency’s documentation guidelines. Failure to maintain acceptable documentation standards can create potential liability for both you and the health care institution.

A Note on Malpractice Insurance

Some employers do not provide malpractice insurance for their nursing employees. Ask your employer exactly who is covered under the employer’s liability insurance and whether those covered parties include you. If nursing employees are covered, the employer’s insurance provides coverage from liability only as long as the employee follows the employer’s work policies and was acting within the scope of employment. For this reason, employer-provided liability insurance is not personal liability insurance. LPN/LVNs often carry personal liability insurance.

HEALTH CARE SYSTEM AND THE LPN/LVN

The LPN/LVN of today must be equipped with knowledge and skills to function successfully in a health care delivery system. An understanding of leadership, delegation, career opportunities, and ethical and legal considerations will provide a basis to begin your journey in practicing as a LPN/LVN. We wish you well on your journey!

REVIEW QUESTIONS

1. The nurse is preparing a presentation on factors influencing health care changes. Which of the following would be a factor to include in the presentation?
   1. Decreasing use of evidence
   2. Increasing older adult population
   3. Decreasing cultural diversity
   4. Decreasing population size in the United States

2. Which of the following actions should the nurse take during admission and throughout a patient’s hospitalization to help ensure reimbursement for a secondary diagnosis occurrence? Select all that apply.
   2. Photograph wounds that are present on admission.
   3. Educate patients about methods used to prevent complications.
   4. Document interventions, such as turning and ambulating patients.
   5. Explain to patient that participation in preventive interventions is optional.

3. Which of these actions would the nurse correctly interpret as falling within the scope of practice of the LPN/LVN?
   1. Performing a physical assessment on admission for a critical care patient.
   2. Administering IV push morphine.
   3. Ambulating a 1-day postoperative patient.
   4. Developing the plan of care for a newly admitted surgical patient.

4. The nurse would like to suggest a new method for documenting intake and output to the nurse manager, who uses the autocratic leadership style. In approaching the manager, the nurse should understand that the autocratic leader makes decisions in which of the following ways?
   1. Seeks information from all staff members.
   2. Uses own knowledge to decide.
   3. Forms focus groups to gather information.
   4. Forms a staff committee to provide input.

5. During orientation, the newly hired LPN/LVN reviews the agency job description for an LPN/LVN. Which of these situations would be an appropriate example of a leadership role for the LPN/LVN within the job description?
   1. Consulting with an RN to modify care for assigned patient.
   2. Performing an annual employee evaluation for a nursing assistant.
   3. Supervising the RN and LPN/LVN staff on a surgical unit.
   4. Interviewing a new graduate RN for a staff position.
6. The nurse is caring for an adult patient admitted for an appendectomy who asks the nurse not to disclose any personal health information including a positive human immunodeficiency virus (HIV) status. The patient’s mother arrives to visit and asks the nurse to explain why her daughter has to take so many medications. Which of the following responses applies the principle of veracity?
1. “You will have to talk to the HCP.”
2. “The medications are for recovery after a surgical procedure.”
3. “The medications are to treat an infection.”
4. “You will need to ask the patient directly about the medications.”

7. A patient with cancer who is having chemotherapy has decided to stop receiving it because the patient has accepted mortality. What is the most ethical response by the nurse to address this situation?
1. Explain to the patient that it would be silly to stop with only eight more treatments left.
2. Explain you are going to call a family member to report this decision.
3. Ensure the patient understands the consequences of discontinuing treatment.
4. Ensure that the patient knows that without treatment, death will occur.

8. A patient with terminal cancer has an advance directive indicating that a feeding tube is not to be inserted. After the patient becomes unconscious, the patient’s family requests that a feeding tube be inserted. Based on a deontological perspective and supporting the patient’s autonomy, what action would the nurse anticipate the HCP will take?
1. Withhold the feeding tube.
2. Insert the feeding tube.
3. Order an electroencephalogram (EEG) to determine if the patient will wake up to be asked about the feeding tube.
4. Place a Do Not Resuscitate (DNR) bracelet on the patient’s wrist.

9. The nurse is assisting in the health clinic offering immunizations for school children. A mother asks the nurse why her children need to be immunized for communicable diseases. The nurse explains that when more children are immunized more people are protected from the communicable diseases. This line of thinking supports which ethical theory?
1. Deontological perspective
2. Utilitarian perspective
3. Theological perspective
4. Autonomy perspective

10. A patient in an extended care facility states that her family does not visit very often. She asks the nurse to give her extra medication so she can die. She states that she’s old and no one will mind anyway. What is the nurse’s best response?
1. “Now that is just silly! Go to the activity room; they are playing bingo.”
2. “I’m sorry, but I cannot do that. Do you want to talk about how you are feeling?”
3. “I can give extra sleeping medicine with lunch so that you can relax more.”
4. “My kids don’t visit me often either, I understand how you feel.”

11. Nurses must abide by which of the following practice guidelines to ensure they deliver appropriate patient care? Select all that apply.
1. Institutional policies
2. An organization’s code of ethics
3. State practice laws for nurses
4. National association nursing standards
5. Locality nursing standards

12. In providing professional nursing care, the nurse understands that the law of negligence requires which of the following to create liability? Select all that apply.
1. A duty of care owed
2. Assault
3. Ethical violations
4. A breach of duty
5. Injury and damages
6. A crime

13. The Health Insurance Portability and Accountability Act of 1996 (HIPAA) requires the nurse to do which of the following? Select all that apply.
1. Maintain continuing nursing education credit hours.
2. Protect the privacy of an individual’s personal health information.
3. Limit nursing work hours to no more than 35 per week.
4. Avoid membership in any union or collective bargaining agreement unit.

Answers can be found in Appendix C.

Cultural Influences on Nursing Care

Bobbi M. Martin

Learning Outcomes

1. Define common concepts related to culture and ethnicity.
2. List examples of cultural characteristics, values, beliefs, and practices.
3. Describe attributes of culturally diverse patients and their families and how they affect nursing care.
4. Identify data you should collect from culturally diverse patients and their families.
5. Apply a holistic approach to patient care that respects cultural characteristics and attributes.

Key Terms

- acculturation (uh-KUL-chur-AY-shun)
- beliefs (bee-LEEFS)
- cultural (KUL-chur-uhl)
- cultural assimilation (KUL-chur-uhl uh-SIM-ih-LAY-shun)
- cultural awareness (KUL-chur-uhl a-WEAR-ness)
- cultural competence (KUL-chur-uhl KOM-petents)
- cultural conflict (KUL-chur-uhl KON-flik)
- cultural diversity (KUL-chur-uhl dih-VER-sih-tee)
- cultural sensitivity (KUL-chur-uhl SEN-sih-TIV-ee-tee)
- cultural shock (KUL-chur-uhl SHOK)
- culture (KUL-chur)
- customs (KUS-tums)
- ethnic (ETH-nick)
- ethnocentrism (ETH-noh-SEN-trizm)
- generalizations (JEN-er-al-i-ZAY-shuns)

- traditions (tra-DISH-uns)
- values (VAL-yooz)
- worldview (WERLD-yoo)
Your clinical instructor has assigned you to provide care to Mary Waters, a 72-year-old African American woman. Ms. Waters has diabetes and hypertension (high blood pressure). She was admitted to the hospital for gangrene of her left foot. When you enter her room, you find Ms. Waters anxious and crying. She tells you that she is scheduled for surgery later in the day. When asked about her foot, she tells you that she has been applying a poultice to draw out the germs, but it has not worked yet. She adds that she has been praying for the cure that she knows will come. As you are collecting history information about her diabetes, Ms. Waters admits that her doctor told her to attend diabetes classes years ago, but she stopped going because she didn’t like what she heard. She quickly changes the subject, wanting to talk about nothing but her grandchildren. Your attempts to complete preoperative teaching are unsuccessful.

Can you think of examples of cultural practices you have seen in your experience that were unique or different from your own? Cultural diversity in the United States is increasing. According to the U.S. Census Bureau, 50.4% of our nation’s population younger than age 1 as of July 1, 2011, were minorities (Bernstein, 2012). Immigration from Spanish-speaking and Asian countries has resulted in dramatic shifts in census numbers. Figure 4.1 illustrates the changes and projections in racial and ethnic makeup in the United States by 2050. As a result, cultural and ethnic differences between nurses and their patients are becoming more evident and must be recognized. More than ever, nurses must develop cultural awareness and apply cultural competence to practice. This chapter provides you with the basics of culture and its impact on health promotion and wellness.

CONCEPTS RELATED TO CULTURE

Culture refers to the socially transmitted behavior patterns, beliefs, values, customs, arts, and all other characteristics of people that guide their view of the world (worldview). Cultural beliefs, values, customs, and traditions are primarily learned within the family on an unconscious level. They can also be learned from the communities in which we live, from religious organizations, and in schools.

As you try to understand more about culture, keep in mind that it contains a number of characteristics (Box 4-1). All individuals and groups have the right to maintain cultural practices that they feel are appropriate, as long as they don’t infringe on rights of others. However, as you will learn from this chapter, nurses must be aware of cultural health practices that can cause physical harm and require nursing intervention. Culture has strong influences on a patient’s understanding of health and how he or she will respond to nursing care. You must understand how culture influences health behaviors to better meet the needs of your patients (Fig. 4.2). As you learn more about ethnic and cultural groups, you will be challenged to look at the differences and similarities across cultures.

Consider our patient, Ms. Waters. Did she behave as you would in a similar situation? How do you think the characteristics of her culture affected her behavior? Can you think of how you could have used the information she shared to engage her in learning more about her upcoming surgery?

Although the terms cultural sensitivity, cultural awareness, and cultural competence are similar, they have different meanings. Cultural sensitivity is knowing politically correct language and not making statements that may offend another person’s cultural beliefs. Cultural awareness focuses on history and ancestry and emphasizes an appreciation for and attention to arts, music, crafts, celebrations, foods, and traditional clothing. Cultural competence includes the skills and knowledge required to provide effective nursing care. To be culturally competent, you need to:

• Have an awareness of your own culture and not let it have an undue influence on your patient care.

• Have specific knowledge about your patient’s culture.
• Accept and respect cultural differences.
• Adapt your nursing care (when appropriate) to your patient’s culture.

We will discuss more about cultural competence later in the chapter.

Although you may have knowledge about another culture, barriers such as ethnocentrism and stereotyping can keep you from appreciating cultural differences. Ethnocentrism is the tendency for humans to think that their ways of thinking, acting, and believing are the only right, proper, and natural ways. Ethnocentrism perpetuates an attitude that beliefs that differ greatly from your own are strange or bizarre and therefore wrong. Additionally, you must be careful not to stereotype your patient. A stereotype is an opinion or belief about a group of people that is ascribed to an individual. For example, the statement “All Chinese people prefer traditional Chinese medicine” is a stereotype. This stereotype is not true. Although many Chinese people may prefer traditional Chinese medicine for some health conditions, not all Chinese people prefer traditional Chinese medicine. However, you can still make generalizations about an ethnic person without stereotyping. Although a generalization or assumption may be true for the group, it does not necessarily fit every individual. Therefore, you must seek additional information to determine whether the generalization fits the individual. The challenge is for you to understand the patient’s cultural perspective. If you have specific cultural knowledge, you can improve therapeutic interventions by becoming a coparticipant with patients and their families. To do this, it is important that you develop a personal, open style of communication and be receptive to learning from patients from cultures other than your own (Fig. 4.3).

A few additional terms important for your understanding of culture relate to the socialization process of those who are learning to become a member of a society or group. When
people immigrate to a new country, many gradually accept the new culture through a learning process. They learn to accept their own beliefs as well as those of their new country. This is known as acculturation. Acculturation is commonly seen in second-generation immigrants because they not only understand the necessity of learning their new culture, but also see the value of it. Learning the new culture helps individuals survive, and more importantly, thrive in their new environment.

Cultural assimilation occurs when a new member takes on the dominant culture’s values, beliefs, and practices, sometimes at the cost of losing some of his or her cultural heritage. This process is often viewed as negative.

Imagine for a moment that you have moved to China. At first you eat the food and try to understand the language of your new country. Over time, you may learn to cook the food, speak the language, and perhaps blend some of the Chinese beliefs, traditions, and practices with your own. This is acculturation. However, this process is not always smooth when one’s own culture conflicts with a new culture, cultural conflict occurs. Worse than that, cultural shock can happen when values, beliefs, and practices sanctioned by the new culture are very different from the ones of the native culture.

Let’s look at another example. Ling Chi is a 4-year-old boy who is a recent immigrant enrolled in a new school. He is alone and afraid, although he is surrounded by other boys and girls his age. It is lunchtime, and while his teacher is trying to help him with his food, he starts crying. The fork and spoon are foreign to him. At home he is used to eating his lunch with chopsticks. In addition, he does not understand the words spoken to him. Ling Chi is experiencing cultural shock.

HEALTH CARE VALUES, BELIEFS, AND PRACTICES

Cultural values, beliefs, and practices about the nature of disease and the human body are central in the delivery of health services, treatments, and preventive interventions (Office of Minority Health, 2010). A value can be defined as a principle or standard that has meaning or worth to an individual (Purnell & Paulanka, 2008). Values can help shape one’s beliefs and practices. Do you know what your values are regarding health and illness? “Cleanliness” is an example of a value. A belief is something that a person accepts as true (e.g., “I believe that germs cause illness and disease”). A practice is a set of behaviors that one follows—for example, washing hands before eating. It is important for you to understand the differences between these terms because we will be discussing them as they relate to cultural groups.

Consider our patient Mrs. Waters again. Can you think of cultural values, beliefs, or practices she has that may influence why she may not want to attend diabetes classes or learn more about her upcoming surgery?

To provide culturally competent care, you need to know how the people you encounter define health and illness. In general, people follow one of three major health belief systems: scientific (Western medicine or biomedical), spiritual, or holistic. You are already familiar with the scientific health system, which dominates health care in Western societies. Belief in supernatural forces dominates the spiritual system, which is considered by many to be an alternative health care system. (Some experts call this magico-religious, but this is an offensive term to some religious persons.) The holistic belief system focuses on the need for balance and harmony of the body and spirit with nature.

Health care typically focuses on health promotion, the prevention of illness, and acute illness care while considering traditional, religious, and biomedical (scientific) beliefs. Additionally, individual responsibility for health, self-medicating practices, views toward mental illness, response to pain, and the sick role are shaped by one’s culture. Most societies combine biomedical health care with traditional, folk, and religious practices such as praying for good health or wearing charms or amulets to ward off illness. There are many examples of folk practices for curing or treating specific illnesses. Think for a minute about such practices that you may perform. What do you do for a fever or a sore throat? Does chicken noodle soup come to mind? Many times folk therapies are handed down from family members and may have their roots in religious beliefs. Examples of folk therapies include covering a boil with axle grease or wearing copper bracelets for arthritic pain. As you will see in Chapter 5, many people use complementary therapies such as acupressure or herbal remedies in addition to traditional Western therapies.

Often folk practices are not harmful and can be added to the patient’s plan of care. However, some therapies may conflict with prescription medications, or cause a toxic effect. Other folk practices may actually cause physical harm to a patient. It is essential to inquire about the full range of therapies being used by your patients, such as food items, teas, herbal remedies, nonfood substances, over-the-counter (OTC) medications, medications prescribed by others, and medications borrowed from others.

If patients sense that you do not accept their beliefs and practices, they may be less open to sharing information and less adherent to prescribed treatment. Your goal is to try to encourage your patients’ practices that could be helpful and discourage those that may be harmful. Before encouraging or discouraging such practices, you will need to discuss them with the appropriate health care team member.

Think about Ms. Waters. Does she use any folk practices? Where can you find more information about her specific folk practices? How would you address this specific situation?

Before moving on, we need to discuss the subjects of mental illness and cultural responses to pain and the sick role. Mental illness may be seen by some as being unimportant compared with physical illness. Mental illness is culture bound. What may be perceived as a mental illness in one society may not be considered a mental illness in another society. Among some cultures, having a mental illness or an emotional difficulty is considered a disgrace and is taboo. As a result, a family is likely to keep a person who is mentally ill at home as long as they possibly can.
Cultural responses to pain and the sick role can vary among cultures. For example, some people are expected to openly express their pain. Others are expected to suffer their pain in silence. For some, the sick role is readily accepted, and any excuse is accepted for not fulfilling daily obligations. Others minimize their illness and make extended efforts to fulfill their obligations despite being ill.

**Nursing Assessment**

To begin your assessment of your patient’s health beliefs, ask the following questions:

- What do you usually do to maintain your health?
- What do you usually do when you are sick?
- What kind of home treatments do you use when you are sick?
- Who is the first person you see when you are sick?
- What do you do when you have pain?
- Do you wear charms or bracelets to ward off illness?
- Do you take herbs or drink special teas when you are sick? If so, what are they?
- Do you practice special rituals or prayers to maintain your health?

**CHARACTERISTICS OF CULTURAL DIVERSITY**

Primary and secondary characteristics of diversity affect how people view their culture. Primary characteristics of cultural diversity include nationality, race, skin color, gender, age, and religious affiliation. Secondary characteristics include socioeconomic status, education, occupation, military experience, political beliefs, length of time away from the country of origin, urban versus rural residence, marital status, parental status, physical characteristics, sexual orientation, and gender issues.

Culturally appropriate care needs to take into account eight cultural phenomena that may vary with use but can be seen in all cultural groups:

1. communication styles
2. space
3. time orientation
4. social organization
5. environmental control/health beliefs
6. choice of health care providers (HCPs)
7. biological variations
8. death and dying issues.

**Communication Styles**

Communication occurs both verbally and nonverbally. Verbal communication includes spoken language, dialects, and voice volume. Dialects are variations in grammar, word meanings, and pronunciation of spoken language. Nonverbal communication includes the use and degree of eye contact, the perception of time, and physical closeness when talking with peers and perceived superiors. In some societies, people are expected to maintain eye contact without staring, which shows that they are listening and can be trusted. However, in other societies, as a sign of respect, people should not maintain eye contact with superiors such as teachers and those in positions of higher status.

**Nursing Assessment and Strategies**

Ask the following questions:

- By what name do you prefer to be called?
- What language do you speak at home?
- Are you able to read and write in English?
- If not, what language is preferred?

Be sure to do the following:

- Take cues from the patient for voice volume.
- Be an active listener, and become comfortable with silence.
- Avoid appearing rushed.
- Be formal with greetings until told to do otherwise.
- Take greeting cues from the patient.
- Speak slowly and clearly. Do not speak loudly or with exaggerated mouthing.
- Explain why you are asking specific questions.
- Give reasons for treatments.
- Repeat questions if needed.
- Obtain an interpreter if needed.

HCPs should refrain from relying on untrained individuals to interpret, especially family members (see “Evidence-Based Practice”). Although it may seem logical that a patient’s best advocate is his or her family, it is risky to rely on family members to interpret medical or health information for the following reasons:

- Family members may not be proficient in medical terminology.
- They may not possess the skills needed to interpret.
- They may unintentionally or intentionally omit or alter important information.
- Using family members to interpret may raise privacy issues protected by the Health Insurance Portability and Accountability Act of 1996 (HIPAA).
- If children are used, they may not be emotionally mature enough to handle the information being conveyed.

**EVIDENCE-BASED PRACTICE**

**Clinical Question**

Do patients with limited English proficiency who have professional interpreters experience improved clinical care over those who use ad hoc or family member interpreters?

**Evidence**

The likelihood of medical errors is significantly reduced by the use of professional interpreters.
versus not using interpreters or the use of ad hoc interpreters. Ad hoc interpreters were much more likely to make errors that led to serious medical problems than professionally trained interpreters (Flores, Abreu, Barone, Bachur, & Lin, 2012).

Implications for Nursing Practice
National Standards on Culturally and Linguistically Appropriate Services recommends that cultural and linguistic appropriate services should be integrated throughout an organization (Office of Minority Health, 2012). Additionally, organizations are required by law to provide language access services to individuals with limited English proficiency (Joint Commission, 2008).

Addressing communication barriers is an important task for nurses as caregivers and patient advocates. Nurses can be aware of the populations they serve and have interpreters available to facilitate communication. This is done through face-to-face interpretation, via phone, or via video. Nurses can also ensure there are written materials in the patients’ native language, especially for discharge instructions. The Joint Commission provides direction and support for HCPs to use health information technology to bridge the cultural gap between HCPs and patients. They note that caregivers who have access to health information technology systems provide better care with improved outcomes (Lopez, Green, Tan-McGrory, King, & Betancourt, 2011).

Tips for Using Interpreters
• Address the patient, not the interpreter.
• Do not interrupt the patient and the interpreter.
• Ask the interpreter to give you exact translations.
• Avoid using medical jargon.

REFERENCES

Space
Space refers to one’s “personal space.” Are you aware of your comfort zone? In other words, how close can someone get to you before you feel less safe and secure? Like you, most people have such a comfort zone. Personal space tends to be different when speaking with close friends versus strangers, and it also differs across cultures. For example, people from the Middle East tend to stand close together when talking, whereas those from European countries, such as Germany, require a much larger space. The need for space is important for the patient’s privacy, autonomy, security, and self-identity. Understanding what space means for your patients can be important when you are trying to assess, treat, and teach them.

Nursing Assessment and Strategies
Ask the following questions:
• Are you comfortable?
• Do you have any concerns you would like to discuss?

Be sure to do the following:
• Make sure your patients are comfortable before you interview them.
• Maintain appropriate physical distance (observe for cues).
• Be aware of cultural differences.
• Be aware of physical objects that may be a barrier to comfort.
• Make sure that the patient’s physical environment is arranged to ensure safety, security, and familiarity.

Time Orientation
Time orientation can vary among people from different cultures. The perception of time has two dimensions. The first dimension is related to clock time versus social time. For example, some cultures have a flexible orientation to time and events, and appointments take place when the person arrives. An event scheduled for 1400 may not be given until 1430 or when a majority of the participants arrive. For others, time is less flexible, and appointments and social events are expected to start at the agreed-on time. For many, social events may be flexible, whereas medical appointments and business engagements start on time.

The second dimension of time relates to whether the culture is predominantly concerned with the past, present, or future. Past-oriented individuals maintain traditions that were meaningful in the past and may worship ancestors. Present-oriented people accept the day as it comes, with little regard for the past; the future is unpredictable. Future-oriented
people anticipate a bigger and better future and place a high value on change. Some people balance all three views—they respect the past, enjoy living in the present, and plan for the future.

Hospitals, clinics, and HCPs’ offices maintain a tight time schedule. It is therefore important that you understand patients’ time orientation so you can prepare them for the timing of appointments, tests, and treatments. In addition, it is important that you assess their usual routines so that you can incorporate these as much as possible into their daily care.

Nursing Assessment and Strategies
Ask the following questions to understand your patients’ time orientation:

- Are you normally on time for appointments?
- Are there any routines that you need to follow?
- What time do you usually eat your meals? Take your bath?

Be sure to do the following:

- Have a clock in the patient’s room.
- Assess for orientation, and reorient to time as needed.
- Prepare patients before a procedure or test.
- Give time options when appropriate. (“Would you like to take a walk now or in an hour?”)

Social Organization
Family organization includes the perceived head of the household, gender roles, and roles of the older and extended family members. The household may be patriarchal (male dominated), matriarchal (female dominated), or egalitarian (shared equally between men and women). An awareness of the family dominance pattern is important for determining which family member to speak to when health care decisions have to be made. Confidentiality issues can complicate this issue. Be sure to follow your institution’s policies when communicating with family members. You may need to obtain the patient’s permission before planning care with family members.

In some cultures, specific roles are outlined for men and women. Men are expected to protect and provide for the family, manage finances, and deal with the outside world. Women are expected to maintain the home environment, including child care and household tasks. You must accept that not all societies share or even desire an egalitarian family structure.

Roles for older adults and extended family vary among culturally diverse groups. In some cultures, older adults are seen as being wise, are deferred to for making decisions, and are held in high esteem. Their children are expected to provide for them when they are no longer able to care for themselves. In other cultures, although older people may be loved by family members, they may not be given such high regard and may be cared for outside the home when self-care becomes a concern.

The extended family is very important in some groups, and a single household may include several generations living together out of desire rather than out of necessity. The extended family may include both blood-related and non-blood-related persons who are given family status. In other families, each generation lives in a separate home or living space.

You can assist your patients with their treatment plans when you have a better understanding of their family dynamics. It is important to know whom to include for planning of care, discharge planning, and patient teaching.

Nursing Assessment and Strategies
Ask the following questions:

- Who makes the decisions in your household?
- Who takes care of money matters, does the cooking, or is responsible for child care?
- Who decides when it is time to see a HCP?
- Who lives in your household? Are they all blood related?

Be sure to do the following:

- Observe the use of touch between family members.
- Let family members decide where they want to stand or sit for comfort.

Environmental Control

Environmental control consists of three major concepts: people’s perception of their ability to control what happens to them and their health, their beliefs about health and illness, and their beliefs in alternative health care therapies such as folk medicine. For example, if a person does not believe he has control of his health, he may not be receptive to nursing interventions that require self-confidence, such as self-administration of insulin. Regarding health beliefs, if a person believes that illness is due to a spiritual cause and not bacteria, he or she may not understand the need to take antibiotics. Third, many people put great faith in folk healing practices. Nurses need to consider their patient’s cultural values and beliefs, especially if they are different from the dominant Western health care view.

Distinctions are made between health and illness and what people do to promote or maintain health and to prevent and treat illnesses. Not all of your patients will turn to a Western health care system or provider. Many people try some form of alternative therapy before seeking treatment. People also use alternative therapies and religious systems such as prayer in combination with the scientific medical system. Religious beliefs and practices may be important to patients (Fig. 4.4).

Nursing Assessment and Strategies
Ask the following questions:

- How do you define health? Illness?
- Do you have any special beliefs about health and illness?
- What do you do to keep well?
- When you feel ill, what is the first thing you do to get better?
- How do you deal with pain?
- How do you and your family express grief?
- Are there any cultural beliefs or practices that I need to know about to plan your care?
Be sure to do the following:

- Be aware of possible cultural beliefs and practices.
- Never stereotype based on what you know about different cultures; always ask for specific information.
- Perform a cultural assessment on all of your patients.
- Ask if patients have received treatments of any kind for their illness.
- Ask about religious beliefs and practices.
- Encourage helpful practices and discourage those that are harmful.

Health Care Providers

HCP choices are made based on the patient’s perceived status and previous use of traditional, religious, and biomedical HCPs. In Western societies, educated HCPs are treated with great respect. However, some people prefer traditional healers because they are known to the patient, family, and community.

It is important to respect differences in gender relationships when providing care. Some people may be especially modest because of their religion, seeking out same-gender nurses and HCPs for intimate care. Respect these patients’ modesty by providing privacy and assigning a same-gender care provider when possible.

Nursing Assessment and Strategies

Ask the following questions of your patients:

- What HCPs besides physicians and nurses do you see when you are ill?
- Do you object to male or female HCPs giving physical care to you?

Be sure to do the following:

- Observe for alternative care providers who may visit the patient in the health care facility.

Biological Variations

The term biological variations refers to ways in which people are different from one another physiologically and genetically. These differences can make them more susceptible to certain illnesses and diseases and may also influence the effectiveness of different medications. Biological variations can include differences in (1) body build and structure, (2) skin color, (3) vital signs, (4) laboratory values, (5) susceptibility to disease, and (6) nutrition. Darker skin color can challenge you to be more observant when you are assessing the skin color of your patient. Laboratory test results can also be different in a number of cultures. For example, American Indians and Hispanic Americans may have higher blood glucose levels than whites.

The term biological variations also refers to differences in nutritional practices. Nutritional practices are currently being scrutinized in our society. These practices include the personal meaning of food, food choices and rituals, food taboos, and how food and food substances are used for health promotion and wellness. Cultural beliefs influence what people eat or avoid. In addition to being important for survival, food offers security and acceptance, plays a significant role in socialization, and can serve as an expression of love.

Culturally congruent dietary counseling, such as adapting preparation practices and including ethnic food choices, can reduce health risks. Whenever possible, you should determine a patient’s current dietary practices. Culturally diverse patients may refuse to eat on a schedule of American mealtimes or to eat American foods. Counseling about food group requirements or dietary restrictions must respect an individual’s cultural background. Most cultures have their own nutritional practices for health promotion and disease prevention. For many, a balance of different types of foods is important for maintaining health and preventing illness. A thorough history and assessment of dietary practices can be an important diagnostic tool to guide health promotion.

Nursing Assessment and Strategies

Ask the following questions of your patients:

- Are you at risk for any diseases or genetic disorders related to your cultural background?
- Are you satisfied with your weight?
- Are you active? What is your normal exercise pattern?
- Do you protect your eyes and skin from the sun? From possible injuries?
- Do you have any drug or food allergies?
- Has anyone in your family had any major illnesses?
- What do you eat to stay healthy?
- What do you eat when you are ill?
- Are there certain foods that you do not eat? Why?
- Do certain foods cause you to become ill? What are they?
- Who purchases the food in your household?
- Who prepares the food in your household?

Be sure to do the following:

- Teach about biological variations that may pertain to your patient.
- Determine and respect usual eating patterns whenever possible.
- Teach good nutrition habits, taking into account patient preferences. Refer to a dietitian if appropriate.

Death and Dying and End-of-Life Issues

Death rituals of cultural groups are the least likely to change over time. To avoid cultural taboos, you must become knowledgeable...
about rituals surrounding death and bereavement. For some, the body should be buried whole. Therefore, an amputated limb may be buried in the amputee’s future gravesite, and organ donation would probably not be acceptable. Cremation may be preferred for some, whereas for others, it is taboo and burial is the preferred practice. Views on autopsy vary. Some cultural groups have elaborate ceremonies that last for days in commemoration of the dead. To some these rituals appear to be a celebration, and in a sense, they are a celebration of the person’s life rather than a mourning of the person’s death. If you are uncertain, find out from the family if there is anything that the health care team can do to facilitate cultural practices.

The expression of grief in response to death varies within and among cultural and ethnic groups. For example, in some cultures, loved ones are expected to suffer the grief of death in silence, with little display of emotion. In other cultures, loved ones are expected to display elaborate emotions to show that they cared for the deceased. These variations in the grieving process may cause confusion if you perceive some people as overreacting and others as not caring. You must accept that culturally diverse behaviors are associated with the grieving process. Bereavement support strategies include being physically present, encouraging reality orientation, openly acknowledging the family’s right to grieve as they need to, helping the family express their feelings, encouraging interpersonal relationships, promoting interest in a new life, and making referrals to other staff and spiritual leaders as appropriate.

At times you may be involved with end-of-life decisions. Some of these may include advance directives, resuscitation status, and organ transplantation. Collaborate with the RN or HCP to ensure cultural preferences are respected.

**Nursing Assessment and Strategies**

Ask the following questions of your patients:

- What are the usual burial practices in your family?
- What are your feelings about autopsy?

Be sure to do the following:

- Observe expressions of grief. Support the family in their expression of grief.
- Observe for differences in the expression of grief among family members.
- Offer to obtain a religious counselor/spiritual leader if the family wishes.

**ETHNIC AND CULTURAL GROUPS IN THE UNITED STATES**

This section describes selected attributes of some of the cultural groups in the U.S. These groups include European American (white), Spanish/Hispanic/Latino, African American (black), American Indian/Alaskan Native, Arab American, Asian American, and Native Hawaiian or Other Pacific Islander. The groups described here by no means represent all the cultural groups in North America; they do, however, represent the largest population percentages in the United States. As of the 2010 census, the U.S. federal government initiated new terminology for classifying people of diverse racial and ethnic backgrounds. This terminology is used in this section.

Attributes presented for each group include communication styles, space, time orientation, social or organization, environmental control, biological variation, health care beliefs, traditional HCPs, and death and dying issues. Racial and ethnic biological variations, susceptibility to disease, and genetic diseases are covered to a greater extent elsewhere in this textbook (see “Gerontological Issues”).

**Gerontological Issues**

**Aging, Ethnicity, Health, and Illness**

Compared with white or European American older adults, ethnic minorities are more likely to:

- Live in poverty
- Experience debilitating disease processes or functional disability at a higher rate and at an earlier age
- Have greater difficulty accessing health care services
- Be underserved for physical and mental health problems.

By 2030, the number of older adults will double. The largest growth will be among minorities. Remember that to provide culturally competent care older adults need to be assessed within their personal cultural context. Avoid generalizing cultural practices to individuals or families without first assessing whether this practice or belief is true for the individual. For example, it would be wrong to assume that an older Mexican American woman who lives with her extended family will receive the family’s support for assistance with bathing and other activities of daily living. If an older Chinese woman uses herbs and folk treatments for common complaints, it does not mean that she will not use the services, treatments, or medications of Western medicine. Always assess individual and family preferences.

**European American**

*European American* is the term used to describe people living in the United States whose heritage is from western, southern, and northern Europe. European American groups include the white ethnic groups. Many of the descendants of these original European immigrants practice the unique attributes of the subcultures from which they originate. There is much diversity in the primary and secondary characteristics of diversity within this cultural group.

Many European Americans maintain the value of individualism over group norms and are activity-oriented. Most European Americans practice Western medicine, which values advanced technology and evidence-based practice (Table 4.1).

</table>
Biological Variations | Nutritional preferences include meats (especially red) and carbohydrates.
---|---
Spanish/ Latino | Nutritional preferences include spicy and fried foods, beans, and rice. Important for food to be served warm. May subscribe to hot and cold theory of illness (e.g., caused when body is exposed to imbalance of hot/cold substances).
African American (Black) | Nutritional preferences include fried foods, barbecued foods, greens, legumes. Diet commonly high in fat and sodium. Food selections may vary according to socioeconomic status and rural versus urban residence. Being overweight is seen as positive.
American Indian/ Alaskan Native | Nutritional preferences vary greatly depending on location and tribe. Nontraditional diets tend to be high in fat and commonly lack fruits and vegetables. Herbs used to cleanse the body of evil spirits and poison.
Arab American | Nutritional preferences include fresh meats and vegetables; may avoid pork and alcohol (Islam). Less likely than general population to smoke, drink alcohol, or use illicit drugs. High risk for diabetes, hypertension, hypercholesterolemia.
Asian Americans | Nutritional preferences include raw fish and rice. Foods are balanced between yin and yang. Diet is high in salt. Food is fundamental form of socialization. Susceptibility: lactose intolerance, thalassemia, liver and stomach cancer, hypertension, coccidioidomycosis.
Native Hawaiian/ Pacific Islander | Nutritional preferences include tubers, fruit, fish and coconut. Susceptibility includes: obesity, type 2 diabetes, hypertension and their resulting cardiovascular and cerebrovascular diseases. Heart valve disorders may be present as rheumatic fever and rheumatic heart disease.

| European American (White) | Have controlled expression of pain but need little encouragement to accept pain relief. Sick role not well accepted except with a major illness. Traditional healers: Western-educated HCPs; recent trend to use complementary therapists. |
| European American (White) | Nutritional preferences include meats, especially red, and carbohydrates. Diets tend to be high in fat and sodium. Eating and drinking may be social rituals. Culture stresses thinness as attractive. |
| European American (White) | Traditional healers: shamans, medicine man, diviners, crystal gazers. |
| European American (White) | Nutritional preferences include fresh meats and vegetables; may avoid pork and alcohol (Islam). Less likely than general population to smoke, drink alcohol, or use illicit drugs. High risk for diabetes, hypertension, hypercholesterolemia. |
| European American (White) | Older patients from specific Pacific regions may use cultural guides or clan leaders such as a “Kahuna lapa‘au” (priest who heals with medicines). A belief illness is due to an imbalance in physical, mental/emotional, and spiritual. |

TABLE 4.1 HEALTH CARE CONSIDERATIONS FOR SPECIFIC CULTURAL GROUPS IN THE U.S.*—cont’d
### Death and Dying Issues

<table>
<thead>
<tr>
<th>Susceptibility: heart disease, breast cancer, diabetes mellitus, thalassemia, Tay-Sachs disease (Eastern European Jewish).</th>
<th>Food choices vary by specific country. Being overweight may be considered healthy. Susceptibility: lactose intolerance, diabetes mellitus, parasites, coccidioidomycosis, gout.</th>
<th>Food is seen as a symbol of health and wealth.</th>
<th>Susceptibility: heart disease, alcoholism, liver disease, diabetes mellitus, tuberculosis, arthritis, glaucoma.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autopsy and burial or cremation usually connected with religious practices or individual preferences. Have varied expressions of grief. Men are expected to be in more control during grief than women.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Burial is the usual practice, rarely cremation; many resist autopsy, the body should be buried whole. May have elaborate ceremonial burial. Women very expressive with grief; men are expected to maintain control.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Susceptibility: keloid formation, lactose intolerance, sickle cell anemia, glucose-6-phosphate dehydrogenase deficiency, thalassemia, sarcoidosis, hypertension, coccidioidomycosis, esophageal and stomach cancers. Death does not end connection between people; body is kept intact after death; prefer no autopsy. Relatives may communicate with the dead person.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Believe body should go into the afterlife whole. Some engage in a cleansing ceremony after touching a dead body. Tribal laws may dictate cremation versus burial. Openly express grief.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Believe death is God’s will. At time of death, bed should face the holy city of Mecca (for Muslims). May perform ritual washing of the body after death. Cremation or autopsy not acceptable. May weep with grief, but limited.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Autopsy not understood by many. Cremation acceptable, but burial also common. Extended grieving time (7 to 30 days) for the more traditional. Expression of grief is highly varied between men and women and among specific countries.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Adapt to change and death is seen as a part of life. There is a belief of a combined body, mind, and spiritual existence.</td>
<td></td>
<td></td>
<td></td>
</tr>

*Although many other cultural groups are represented in the United States, the most common are presented here.

Source: Bernstein, 2008.
Spanish/Hispanic/Latino

The term Spanish/Hispanic/Latino is used to describe people whose cultural heritage has a strong Spanish influence. However, many people in this group prefer to identify themselves as Chicano or with terms that provide a country of origin, such as Mexican, Peruvian, Puerto Rican, and Cuban (Purnell & Paulanka, 2008). The population breakdown of Spanish/Hispanic/Latino populations in the U.S. is Mexican Americans (63%), Puerto Rican (9.2%), Central and South Americans (13.4%), Cuban (3.5%), and other groups, including the Dominican Republic (23.3%; U.S. Census, 2011). Hispanics immigrate from any number of Central and South American countries, the Caribbean, and other Spanish-speaking countries. Thus, there is much diversity in this population in the United States.

Some Spanish/Hispanics/Latinos speak only Spanish, only English, or both Spanish and English, whereas others speak neither Spanish nor English but rather an Indian dialect. The spoken language depends on individual circumstances and the length of time spent in the United States. Spanish is the second most commonly spoken language in the United States.

Spanish/Hispanics/Latinos comprise approximately 17% of the U.S. population (U.S. Census Bureau, 2011); they recently became the majority minority population. They live in all 50 states with more than 90% living in and around cities. Four of every five Spanish/Hispanics/Latinos are born and raised in the United States. Many of these individuals have come from poverty and have few opportunities for advancement. They sacrifice for their basic needs (Figs. 4.5 and 4.6).

Most Spanish/Hispanics/Latinos practice adaptations of the Roman Catholic religion. Their close relationship with God makes it acceptable for people to have visions and dreams in which God or the saints speak directly to them. Thus, HCPs must be careful not to attribute these culture-bound visions to hallucinations that indicate a need for psychiatric services (see Table 4.1).

African American/Black

African Americans/blacks are the third largest ethnic group in the United States and represent more than 100 racial strains. They make up 13% of the population (U.S. Census Bureau, 2011). Although African Americans/blacks live in all 50 states, more than half live in the South. It is important to understand that not all people with dark skin identify themselves as African American. Many black-skinned people from the Caribbean use terms more specific to their identity, such as Haitian, Jamaican, or West Indian.

African Americans/blacks have been called by many names. Their ancient African name is Nehesu or Nubian. During slavery days in America, they were called Negro, a Spanish-Portuguese word meaning “black.” After emancipation in 1863, they were called colored, a term adopted by the First Colored Men’s Convention in the United States in 1831. The U.S. Bureau of the Census adopted the word Negro in 1880. During the civil rights movements in the 1960s, the term black was used to signify a philosophy of life instead of color. In the 1970s, these ethnic peoples referred to themselves as African Americans because they were proud of both their African and American heritages. In 1988, the term African American was widely adopted in the United States by those
whose ancestry originated from Africa. These terms continue to cause confusion when people try to use the “politically correct” term in this country. Additionally, titles such as the National Black Nurses Association and the National Association for the Advancement of Colored People (NAACP) still exist.

African Americans/blacks are underrepresented in colleges and universities, managerial and administrative positions, and the health care professions. They are overrepresented in high-risk, hazardous occupations such as the steel and tire industries, construction industries, and high-pollution factories (see Table 4.1) The 2008 election of Barack Obama, the first African American U.S. president, and his reelection in 2012, brought about education initiatives including outreach programs for low-income families and increased availability of advance placement classes nationwide. This will likely have an impact on such issues in the future.

CRITICAL THINKING

Ms. Waters

- Now that you have learned more about culture, let’s look at Ms. Waters again. Review Table 4.1 and answer the following questions:

1. What does your interaction with Ms. Waters tell you about her time orientation?
2. What is evident about her social organization?
3. What biological variations may Ms. Waters demonstrate that are likely part of her culture?
4. Who might you involve in discussions with Ms. Waters about her health? About her upcoming surgery?
5. Where might you learn more about the unique health practices Ms. Waters uses to address her health concerns?

Suggested answers are at the end of the chapter.

American Indian/Alaskan Native

There are more than 400 American Indian/Alaskan Native tribes in the United States, totaling 1.7% of the population (U.S. Census Bureau, 2011). Although there are similarities among American Indians, each tribe has its own unique perspective on health and illness. The preference of American Indians is to be referred to by their tribal names, but if the tribal name is not known, the term American Indian or Native American is acceptable.

Many traditional American Indians/Alaskan Natives live on reservations; others live in urban areas and practice few of their traditions. Many American Indians/Alaskan Natives have a strong belief that illness is caused by an imbalance with nature and the universe. Tribal identity is maintained through powwows, ceremonial events, and arts and crafts that are taught to children at a young age. Communicating with nature is important for maintaining life forces. American Indians/Alaskan Natives are the original inhabitants of North America.

American Indians/Alaskan Natives are underrepresented in all of the health professions. They are consistently identified as the most underrepresented minority group in institutions of higher learning (Bernstein, 2008). (See Table 4.1, Cultural Considerations.)

Arab American

Arab Americans are a large and diverse population, with more than 3,000,000 in the United States. Some common bonds include the Arabic language and the Islamic religion. Arab Americans include people from Morocco, Algeria, Tunisia, Libya, Sudan, Egypt and the western Asian countries of Lebanon, occupied Palestine, Syria, Jordan, Iraq, Iran, Kuwait, Bahrain, Qatar, United Arab Emirates, Saudi Arabia, Oman, and Yemen. Many early Arab immigrants were Christians from Lebanon and Syria.

Although many Arab Americans favor professional occupations, they are often underemployed. Others have their own businesses or work in a variety of other occupations. Arab Americans, whether born in the United States or in Arab countries, are more educated than the average American. They are more likely to be in managerial and professional specialties than any other ethnic group in America. However, a significant number of primarily foreign-born Arab Americans are unemployed and live in poverty.

Asian American

This large group is far from homogeneous. The term Asian, as used in most references, includes 32 groups and refers to a person having origins in the Far East, Southeast Asia, or the Indian subcontinent. These groups include Asians, Indochinese, and other Asian groups. Asians include people from Korea, Japan, and 54 ethnic groups from China; Polynesians; Filipinos; Malaysians; and Guamanians. Indochinese populations include Cambodian, Vietnamese, Hmong, and Laotian. Other Asian groups include Asian Indian, Pakistani, and Thai. Although it is difficult to determine exact numbers of Asians from specific countries because of the method of keeping population statistics, they are a significant and fast-growing population in the United States.

It is important for many Asian patients to “save face.” Individual shame is shared with the family and community. Most Asians see the nurse as an authority figure. Although known by different names, most Asian cultures practice the yin and yang balance of forces for illness prevention and maintaining health. Yin is considered female and represents cold and weakness. Yang is considered male and represents strength and warmth. Foods and all forces are classified as yin or yang and must be balanced or illness occurs. Yin and yang forces are major components of traditional Chinese medicine, which includes acupressure, acupuncture, and cupping (see Table 4.1).
Native Hawaiian/Pacific Islander

Native Hawaiian or Other Pacific Islander refers to a person having origins in Hawaii, Guam, Samoa, or other Pacific Islands. The majority of the Native Hawaiian/Pacific Islander population resides in Hawaii and California. In American homes, there are at least 39 Pacific Island languages spoken as a second language; 14% of Native Hawaiian and Pacific Islanders have limited English proficiency compared with the general population.

Native Hawaiian and Pacific Islanders have multiple health concerns. Native Hawaiians are more likely to have diabetes and have higher death rates due to cancer. Pacific Islander children have the highest rates of HIV infection and the second shortest AIDS survival rate of all Americans. Poverty remains a problem among this population with almost 20% living in poverty and 18% living below poverty (White House Initiative on Asian Americans and Pacific Islanders, 2010; Wergowske & Blanchetter, 2010).

CULTURALLY COMPETENT CARE

The American Nurses Association (2013) supports the need for nurses to understand cultural diversity and to become culturally competent. However, there is no real agreement as to how your knowledge, skills, and attitudes will best help these diverse populations. You certainly cannot achieve cultural competence overnight; it is a developmental process. Each time you care for a patient from a different culture, you learn more, become more aware and sensitive to individual needs, and move toward becoming culturally competent.

The following strategies for providing culturally competent care may be helpful:

- Consider each of your patients as unique, influenced but not defined by his or her culture.
- Know your own cultural values, beliefs, and practices, and appreciate how they may be different from those of others.
- Never let your own biases about people and groups stand in the way of culturally competent care.
- Learn as much as you can about cultural groups in your community.
- Make an effort to include beliefs and practices from other cultures into your care when appropriate.
- Try to encourage helpful cultural practices and discourage harmful ones.
- Be aware of how you communicate with others; be aware of verbal and nonverbal patterns.
- Respect your patients regardless of their cultural backgrounds.
- Learn from your mistakes.

This list does not include everything you can do. Can you think of other strategies?

CRITICAL THINKING

The Lopez Family

- Jose, age 23, and his wife, Louisa, age 19, immigrated to the United States 3 years ago from Mexico. They have two children, Maria, 3 years old, and Jesus, 6 months old. The young couple has brought the children to the emergency room for the treatment of ear infections. Jose informs you that Maria has a sore throat and ear pain and Jesus is “fussy” and not eating. He states that he has been to his curandero, but neither child has improved. You also notice that the children are dressed in heavy clothing, although it is quite warm outside. When you question the parents, Louisa responds that they are “cold.”

Jesus is admitted to the hospital for dehydration. As you are admitting the infant to your unit, you are aware that Jose is answering all of your questions and making decisions for Jesus’s care. He states that they will all need to spend the night with Jesus. Jose further adds that Jesus needs more clothes on and that the temperature in the room needs to be increased. The parents refuse the warmed bottle of formula for Jesus but ask for it to be chilled. Louisa sits in the corner of the room chanting, crying, and rubbing some beads.

What nonverbal communication characteristics do these parents display that are common among people of Spanish descent?

1. Why do you think the children are dressed inappropriately for the weather?
2. Do Jose’s demands mean that he is uncooperative and trying to control the care of his son?
3. Why do you think Jose refused his son’s warm bottle?
4. What is the significance of Louisa’s behavior?
5. What might you do to improve Jesus’ care?
6. How will you handle the father’s request for the entire family to stay in your patient’s room?
7. How can you become more culturally competent in this situation?
8. Are there other members of the health team that might be helpful in this situation?

Suggested answers are at the end of the chapter.
**UNIT ONE**

**Understanding Health Care Issues**

**REFLECTIONS ON MS. WATERS**

After learning more about culture, how do you think the characteristics of Ms. Waters’ culture affected her behavior? At her age, it is evident that she has learned many of her beliefs and practices about health and illness from others. Although many of her behavior(s) can be explained by fear and denial, it is probable that other things are going on in this situation. Ms. Waters may feel more comfortable with people of her own culture, at least when it comes to asking for health information. She may not trust biomedical or Western medicine treatments. She may be more comfortable with the practices and healers that she knows better. Can you think of other explanations?

Rarely do practicing nurses have the luxury to assess each patient comprehensively on a first encounter. The essentials for culturally competent care are obtained as needed over time. As you meet patients from other cultures, continue to learn about these new cultures. Astute observations, openness to diversity, and willingness to learn from patients are essential for effective cross-cultural competence in clinical practice. Cultural competence is not a luxury; it is a necessity.

**SUGGESTED ANSWERS TO CRITICAL THINKING**

**Ms. Waters**

1. African Americans may be present-oriented. Her seeming lack of concern about her diabetes may reflect hesitance to worry about a future that is not here yet.
2. Family is important. She prays for healing.
3. We do not know Ms. Waters’s weight, but overweight may be seen as positive in her culture, and excess weight is a risk factor for diabetes and hypertension.
4. Involving family members, both younger and older, might be helpful with Mrs. Waters’s permission. You might want to ask if there is a religious person whom she might want to include in discussions and decision making.
5. Most institutions have resources for cultural assessment and practices. If you are using Internet-based resources, be sure they are credible resources and that your facility approves of the information obtained.

**The Lopez Family**

1. Jose’s behavior indicates that he is the primary decision maker and in charge of this situation. Louisa’s crying is normal. She is most likely praying.
2. This may relate to the couple’s beliefs in the hot and cold theory.
3. His role as father may dictate that he should maintain control. He probably does not mean to be uncooperative.
4. Again, this may be related to hot and cold beliefs about treatment of diseases.
5. Louisa’s culture-bound role dictates that she not assume control of the situation. She is upset and praying.
6. Attempt to incorporate the family’s cultural beliefs and practices when possible.
7. Explain that it would not be good for Maria to remain in the hospital because she will be at greater risk for exposure to infection. Ask if there are other relatives who can care for Maria. Find out if the parents can divide their time with their son.
8. Be aware of your own cultural beliefs, appreciate your patient’s culture, learn more about the Lopez family’s culture (ask questions), and include their beliefs and practices when possible. Explain if there are practices that cannot be followed. Ask for alternatives.
9. Many hospitals have identified health care personnel from specific cultural backgrounds who are recommended as consultants to provide guidance to nurses. Review your hospital resources and locate additional resources if necessary. Find out whether your facility has a cultural competence task force or committee that you can become a part of, or develop one if this does not exist.
Chapter 4  Cultural Influences on Nursing Care

Chapter 4  Cultural Influences on Nursing Care

REVIEW QUESTIONS

1. Which of the following characteristics is exhibited by a nurse who assumes that all patients have the same cultural beliefs as his or her own?
   1. Cultural stereotyping
   2. Ethnocentrism
   3. Cultural sensitivity
   4. Cultural dominance

2. A 12-year-old Mexican American child is admitted for an appendectomy. His parents bring in the priest from their church to pray over the child. The prayers are continuing when it is time to take the child to surgery. How should the nurse respond?
   1. Gently tell the parents that they must stop praying so the child can be taken to surgery.
   2. Give the parents and priest as much time as they need for prayers before surgery.
   3. Tell the parents that the child could die from a ruptured appendix if surgery is delayed.
   4. Permit the parents and priest to stay and pray as the child goes into surgery.

3. An Osage American Indian woman is slow at giving responses and does not maintain eye contact with the nurse when her admission interview is being conducted. Which of the following interpretations of her behavior is most likely accurate?
   1. Direct eye contact may be interpreted as rude in her culture.
   2. She does not want to answer personal questions.
   3. She does not understand the nurse.
   4. She does not want to talk with a nurse and prefers a physician.

4. An Arab American man is refusing his dinner tray, which consists of potatoes with cheese, a slice of ham, and green beans. What knowledge should guide the nurse’s data collection related to this incident?
   1. Arabs do not like foods from different sources on the same plate.
   2. Some Arabs do not eat dairy products.
   3. Islamic Arabs may not eat pork.
   4. Arabs typically do not eat vegetables.

5. A Puerto Rican man has been admitted for reconstructive orthopedic surgery on his knee. His wife brings jars of special blends of spices that he wants to put on his food because the hospital food is too bland. He is on a general diet. What action should the nurse take?
   1. Check to be sure they do not interact with his medications and let him use them.
   2. Carefully explain that family cannot bring food items to the hospital.
   3. Have the dietitian provide spices from the hospital food services.
   4. Report the situation to the HCP.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Explain the difference between complementary and an alternative modalities.
2. Describe selected systems of health care that have contributed to the development of new modalities.
3. Identify how the different types of modalities are classified.
4. Identify safety issues associated with complementary and alternative modalities.
5. Describe the role of the licensed practical nurse/licensed vocational nurse (LPN/LVN) in assisting a patient with complementary and alternative modalities.
Chapter 5  Complementary and Alternative Modalities

Health care in the 21st century requires that nurses recognize the shift toward the inclusion of complementary and alternative approaches in care. Nurses at all levels and in every area of practice are answering the call to use new methods to care for those who are ill and enhance the health of those who are well.

Holistic nursing was a precursor to many of the now popular complementary and alternative modalities. It was introduced in the 1970s and has been growing ever since. Holistic nursing is simply defined as caring for the whole person—body, mind, and spirit—in a constantly changing environment.

**COMPLEMENTARY OR ALTERNATIVE: WHAT’S THE DIFFERENCE?**

The words _complementary_ and _alternative_ are sometimes used interchangeably, but they are not the same. _Complementary therapy_ refers to a therapy used in addition to a conventional therapy. For example, a nurse might suggest guided imagery, music, and relaxation techniques for pain control in addition to prescribed drug therapy. _Alternative therapy_, sometimes called _unconventional therapy_, refers to a therapy used instead of conventional or mainstream therapy. An example is using acupuncture instead of analgesics for pain. The terms _therapy_, _modality_, and _medicine_ are used interchangeably. For consistency, this chapter uses the term _modality_.

A good resource for current information about complementary and alternative modalities is the National Center for Complementary and Alternative Medicine (NCCAM) at www.nccam.nih.gov. To learn about holistic nursing and complementary modalities, visit the American Holistic Nurses Association at www.ahna.org.

**INTRODUCTION OF NEW SYSTEMS INTO TRADITIONAL WESTERN HEALTH CARE**

There are many new and different philosophies within the scope of expanded medical and nursing practice. These systems reflect cultures and attitudes in healing that range from East to West and from ancient to modern. In a landmark study, Eisenberg et al. (1993) reported that unconventional therapy use in the United States far exceeded previous estimates. Of the 1539 adults interviewed, one in three (34%) reported using at least one unconventional modality during the previous year. More recent findings confirm that this trend is increasing, indicating a need for more systemic approaches to care. As systems use complementary and alternative modalities, nurses and allied health personnel are increasingly using new and different philosophies and methods to care for those who are ill and enhance the health of those who are well.

Holistic nursing was a precursor to many of the now popular complementary and alternative modalities. It was introduced in the 1970s and has been growing ever since. Holistic nursing is simply defined as caring for the whole person—body, mind, and spirit—in a constantly changing environment.

The words _complementary_ and _alternative_ are sometimes used interchangeably, but they are not the same. _Complementary therapy_ refers to a therapy used in addition to a conventional therapy. For example, a nurse might suggest guided imagery, music, and relaxation techniques for pain control in addition to prescribed drug therapy. _Alternative therapy_, sometimes called _unconventional therapy_, refers to a therapy used instead of conventional or mainstream therapy. An example is using acupuncture instead of analgesics for pain. The terms _therapy_, _modality_, and _medicine_ are used interchangeably. For consistency, this chapter uses the term _modality_.

**Ayurvedic Medicine**

Ayurveda is the ancient Hindu system of medicine, which originated in India. Ayurvedic medicine’s main goals are to maintain the health of well people and cure the illnesses of sick people. Ayurveda maintains that illness is the result of falling out of balance with nature. Diagnosis is based on three metabolic body types called _doshas_. An Ayurvedic doctor determines which _dosha_ type is most appropriate for the patient: _vata_, _pitta_, or _kapha_. Treatment usually involves

* WORD BUILDING *

- **allopathic**: allo—other + pathic—disease or suffering
- **Ayurvedic**: ayu—life + veda—knowledge or science
prescribing a diet, herbal remedies, breathwork, physical exercise, yoga, meditation, massage, and a rejuvenation or detoxification program.

Ayurveda is rapidly becoming more popular in America. The books and videos of Deepak Chopra are examples of this increasingly popular system of therapy. An introduction to Ayurveda can be found at http://nccam.nih.gov/health/ayurveda/introduction.htm.

Traditional Chinese Medicine

Traditional Chinese medicine is thousands of years old and involves such practices as acupuncture, acupressure, herbs, massage, and qi gong. Chinese medicine involves diagnosis and treatment of disturbances of qi (pronounced “chee”), or vital energy.

Acupuncturists, one type of traditional Chinese medicine practitioners, claim to be able to tell much about a patient’s state of health by checking pulses, looking at the color of the tongue, checking facial color, assessing voice and smell, and asking a variety of questions. To treat patients with acupuncture, practitioners insert one or more needles along the meridians (paths) where qi flows (Fig. 5.1). Many acupuncturists prescribe herbal remedies as well. Find information on how acupuncture is being integrated into Western medicine at http://nccam.nih.gov/health/acupuncture.

Chiropractic Medicine

Have you ever been to a chiropractor? Daniel David Palmer founded chiropractic therapy in 1895. Chiropractic medicine is based on the belief that illness is a result of neuromusculoskeletal dysfunction. The main treatment modality of chiropractors is manual adjustment and manipulation of the vertebral column and the limbs. They use direct hand contact and mechanical and electrical treatment methods to manipulate joints. The goal is to remove interference with nerve function so the body can heal itself. Chiropractors do not perform surgery, nor do they prescribe drugs. Review the American Chiropractic Association website at www.acatoday.org/level1_css.cfm?T1ID=42 for additional information.

\* WORD \* BUILDING \*

acupuncture:acus—needle + punctura—puncture
chiropractic: cheir—hand + praktos—to do

FIGURE 5.1 Qi meridians are used in the Chinese medicine techniques of acupressure and acupuncture.
Homeopathic Medicine

Homeopathy was developed by Samuel Hahnemann in Germany in the early 19th century. Homeopathy is based on Hahnemann’s principle that “like cures like,” meaning that tiny doses of a substance that create the symptoms of disease in a healthy person will relieve those symptoms in a sick person.

Although schools and courses do exist for training homeopaths, no diploma or certificate from any school or program is a license to practice homeopathy in the United States. Medical doctors and doctors of osteopathy are granted national certificates of competency by the Council for Homeopathic Certification to practice homeopathy. Other health care practitioners may be allowed to use homeopathy within the scope of their state licenses.

Visit the National Center for Homeopathy website at www.nationalcenterforhomeopathy.org. This site has a research section with annotated listings from the medical literature discussing the value of homeopathy. In addition, the site has a good review of licensing laws regarding homeopathy.

Naturopathic Medicine

Naturopathy primarily uses natural therapies such as nutrition, botanical medicine (herbs), hydrotherapy (water-based therapy), counseling, physical medicine, and homeopathy to treat disease, promote healing, and prevent illness. Naturopathic physicians have a doctor of naturopathy (ND) degree and can be licensed in 17 states. There are three schools of naturopathic medicine in the United States. For more information about naturopathy, visit www.naturopathic.org.

American Indian Medicine

American Indian medical practices vary from tribe to tribe. In general, American Indian medicine is a community-based system with rituals and practices such as the sweat lodge, herbal remedies, the medicine wheel, the sacred hoop, the “sing,” and shamanistic healing. For example, an ill person may be placed in a small, enclosed sweat lodge while singing or chanting is done outside the lodge. It is believed that toxic substances are drawn out in the sweat of the person inside the lodge. After the ceremony, the ill person may be placed on a cot outside and be prayed over. Learn more about American Indian medicine at the Association of American Indian Physicians’ website at www.aaip.org.

Osteopathic Medicine

Osteopathic medicine was founded in the United States in 1874 by Andrew Taylor Still, a frontier physician who was dissatisfied with the state of medicine at that time. This practice of medicine emphasizes the interrelationship of the body’s nerves, muscles, bones, and organs. The osteopathic philosophy involves treating the whole person, recognizes the body’s ability to heal itself, and stresses the importance of diet, exercise, and fitness with a focus on prevention. For more information about osteopathy, visit the American Osteopathic Association website at www.osteopathic.org.

Complementary and Alternative Modalities

Discussion of all complementary and alternative modalities is beyond the scope of this text. Table 5.1 summarizes the most commonly used modalities.

Herbal Therapy

Have you ever tried herbs for healing? Herbs should only be taken under the supervision of a HCP. Herbs can aid in healing, but they also can do harm. Some of the more common herbs are described in Table 5.2. Figure 5.2 shows echinacea, an herb commonly prepared for use as an immune system booster.

It is important to note that herbal remedies are not foods. They have potent medicinal effects and can interact with prescribed medications and even complicate surgery. This can be problematic, both because herbs are readily available in health food stores and drugstores and because many patients do not tell their doctors or nurses about their herb use. For example, three common herbs, garlic, ginkgo, and ginseng, can each increase the risk of bleeding when taken with anticoagulant or antiplatelet medications. Another popular herb is St. John’s wort, widely used for depression. It can interact adversely with many drugs, including other antidepressant agents. Be sure to assess patients’ use of herbs and supplements and educate them about the need to inform HCPs, including their pharmacists, when using herbs.

### Table 5.2 Common Herbs and Their Intended Uses

<table>
<thead>
<tr>

<td>St. John’s wort</td>
<td>May help mild to moderate depression; may be effective against viral infections, including HIV and herpes</td>
</tr>
</tbody>
</table>

*Warning:* Herbs may have many side effects and may interact with many prescribed and over-the-counter medications. Urge patients to consult HCPs before self-prescribing.
A great website for you and your patients is www.mayoclinic.org. Just type in the common herb you want to know about in the search window for up-to-date information. It even has an Evidence section that grades the evidence of the herb’s effectiveness for each disorder it is supposed to treat. Grades range from A, which indicates strong research evidence for the herb’s use, to F, which indicates strong evidence against its use.

Relaxation Therapies

Progressive Muscle Relaxation

Progressive muscle relaxation is a simple technique to learn. It involves the process of alternately tensing and relaxing muscle groups. Often this process is performed in a systematic manner such as from toes to head. The purpose of the technique is to help the participant identify subtle levels of mental and physical tension that accompany mental and emotional stress. When our conscious awareness of the tensions increases, we can learn to relax and thus reduce the effects of stress and tension.

Biofeedback

Biofeedback could be considered the third tier of learning progressive relaxation. This technique is used especially for conditions that are aggravated by stress such as asthma, migraines, insomnia, and high blood pressure. Biofeedback is a way of monitoring and controlling tiny metabolic changes in one’s body with the aid of sensitive machines that provide feedback (“Patient Perspective”).

Guided Imagery

Guided imagery is another example of a complementary therapy that many nurses use. Guided imagery involves using mental images to promote physical healing or changes in attitudes or behaviors. Practitioners may lead patients through visualization exercises or offer instruction in using imagery as a self-help tool. Guided imagery is often used to alleviate stress and to treat stress-related conditions such as insomnia and high blood pressure. People with cancer, AIDS, chronic fatigue syndrome, and other disorders can use specific images to boost the immune system.

A common guided imagery technique begins with a general relaxation process. For those new to the process, it is good to begin with the progressive muscle relaxation as explained earlier in the chapter. Guided imagery works best when all of the senses are used. The exercise in Box 5-1 is very basic but gives an idea of how the technique works. When used for healing, many more steps are involved. It is important to note that appropriate training and skills are needed before using complementary and alternative modalities with patients. Find more on guided imagery at www.nccam.nih.gov; type “guided imagery” into the search window.

Box 5-1 Guided Imagery

Assist your patient to progress through the following steps:

- Assume a comfortable position in a quiet environment.
- Close your eyes and keep them closed until the exercise is completed.
- Breathe in and out deeply to the count of four, repeating this step four times.
- When relaxed, think of a favorite peaceful place and prepare to take an imaginary journey there.
- Picture what this place looks like and how comfortable you feel being there.
- Listen to all the sounds; feel the gentle, clean air; and smell the pleasant aromas.
- Continue to breathe deeply and appreciate the feeling of being in this special place.
- Feel the sense of deep relaxation and peace of this place.
- As you continue to breathe deeply, slowly and gently bring your consciousness back to the setting in this room.
- Slowly and gently open your eyes, stretch, and think about how relaxed you feel.

Patient Perspective

I’m scared to death of flying. The minute I get on an airplane, I feel jittery, my heart races, and I can’t calm down until we’re safely back on the ground. Several years ago, I decided to try biofeedback therapy to overcome this fear.

My therapist was wonderful. She immediately put me at ease and assured me I wasn’t a crazy person to be afraid to fly. She listened to my fears and responses throughout all our sessions. At each practice session, she put a temperature sensor on my finger (my hands were usually pretty cold). In her calm, soft voice, she guided me through a relaxation exercise using imagery and progressive muscle relaxation. By the time we were finished, my hands would be several degrees warmer than when we started! This showed my vessels were dilating, a sign that my sympathetic nervous system was slowing down its activity. So I felt calmer. The sensor gave me feedback...
that told me when my relaxation was working well. We did this every week for a couple of months, until I got really good at warming my hands and relaxing. Now when I fly, I close my eyes, imagine a peaceful scene and use my relaxation techniques. I still don’t like flying much, but at least I feel a bit calmer!

**Massage Therapy**

Massage is the use of touch to achieve therapeutic results and can include pressure, friction, and kneading of the body. Massage can be used to relax muscles, reduce anxiety, increase circulation, and reduce pain.

Massage also provides a caring form of touch. In the past, a back massage was a nightly routine for hospitalized patients, helping them relax for sleep. Sadly, patients today are often not touched except during technical procedures.

You can learn basic massage techniques in nursing school. You may also choose to obtain formal massage therapy education to practice more advanced techniques. Try giving your patient an old-fashioned back massage, and see how delighted he or she is!

---

**Aquatherapy**

Sitting in a warm tub can feel good as aching, tired muscles relax and mental stress is decreased. People who suffer from arthritis or other chronic pain understand how warm water can ease their discomfort. Relaxing in water feels good for three reasons: warmth, water movement causing massage, and buoyancy.

Long before analgesics were developed, the human body relied on its own naturally occurring, internally generated, pain-killing chemicals called endorphins. Endorphins are released in response to both acute and chronic pain. Through research we now know that warm water also stimulates the release of endorphins.

The most recognized methods to release endogenous (naturally occurring) endorphins are physical exercise, acupuncture, and electrical nerve stimulation. Any type of skin stimulation (even the mechanical impact of water) can cause the release of endorphins. However, pain reduction is only part of the healing process. Ultimately, blood flow is what brings nutrients to damaged cells and facilitates healing. When the body is immersed in warm water, the blood vessels nearest the skin relax, allowing more blood to flow. The results are faster tissue repair and relief of pain and fatigue.

---

**Heat and Cold Application**

Local application of heat or cold provides additional skin stimulation. A warm compress can soothe sore muscles and dilate vessels in a defined area, bringing healing circulation as well as endorphin release. Ice or a cold gel pack can help numb an area. Cold can also cause overdilated vessels to constrict, yielding relief from pain and throbbing of overstimulated nerve endings. Ice can be helpful on an acute injury and for some types of headaches. Check institution policy before applying heat or cold; a physician's order may be required.

**Probiotics**

Probiotics are considered beneficial bacteria, and their use is increasing in popularity. The Food and Drug Administration has not approved any health claims related to probiotics. Common reasons for taking probiotics are to aid in healthy digestion or to treat constipation or infectious diarrhea. Increased stress, unhealthy eating patterns, and hectic schedules can disrupt balanced digestion in individuals. Nurses need to caution individuals to discuss plans to take probiotics with their HCPs. It is important to review the research available on a particular product because there are many strains available. Also, it is essential to consider where the research was published (preferably in a peer-reviewed journal) and examine the findings on how safe the product is. Additional information on probiotics can be found at www.nccam.nih.gov.

---

**SAFETY AND EFFECTIVENESS OF ALTERNATIVE MODALITIES**

Safety generally means that the benefits outweigh the risks of a treatment or therapy. If a patient is interested in using complementary and alternative modalities, the nurse first needs to counsel the patient to talk with the primary care provider. The patient also should ask the practitioner of the therapy about its safety and effectiveness. Patients should tell their primary care providers and alternative practitioners about all therapies they are using because this information may be important to consider in the safety of their entire treatment plan.

The patient should be as informed as possible and continue gathering information even after a practitioner or therapy has been selected (Box 5-2).

---

**ROLE OF THE LPN/LVN**

Patients may ask you about the use of a complementary or alternative modality. Because the safety and effectiveness of many therapies is still unknown, advising patients presents a challenge. The following steps are suggestions for helping to advise patients regarding the use of these kinds of therapies:

1. Advise the patient to take a close look at the background, qualifications, and competence of the proposed practitioner. Check credentials with a state or local regulatory agency with authority over the area of practice in which the patient is interested. Is the practitioner licensed or certified? By whom?
Chapter 5

Complementary and Alternative Modalities

Before incorporating complementary and alternative modalities into practice, be sure to check your state’s nurse practice act for any regulations. Discuss these therapies with the patient and his or her primary care provider before using them. If you work for a hospital or other health care institution, also check institutional policy. See “Evidence-Based Practice” for ways nurses are implementing various modalities in practice.

As the public learns more about complementary and alternative modalities, there is likely to be an even greater demand for them. Nurses have been in the forefront of developing the holistic philosophy that has now become an accepted standard of care.

NURSING APPLICATIONS

There are ways to gain confidence with complementary and alternative modalities:

- Begin by trying one or two of these modalities yourself. Start by choosing a basic therapy such as massage, music, or guided imagery. Follow the guidelines listed in Box 5-2 to make sure it is a safe strategy. Not only will you encounter the possible benefits firsthand, you will also come away with a better understanding of what your patients experience with a given modality.
- Ask your patients if they use any complementary or alternative modalities and what their responses to them have been. Try to eliminate any preconceived notions you might have. Your patients will feel more comfortable mentioning them to you if they feel you understand the treatment and why they decided to use it.
- If you decide to become involved, get instruction in the therapies before you administer them. Many universities and agencies offer continuing education courses on these therapies, and some nursing schools incorporate complementary and alternative modalities in their skills courses. Of course, you will also want to discuss the therapy with your workplace before trying it on a patient!

Box 5-2 Questions Patients Should Ask Before Starting a Complementary or Alternative Modality

1. What will this modality do for me?
2. What are its advantages?
3. What are its disadvantages?
4. What are its side effects?
5. What are its risks?
6. How much will it cost? Will my insurance cover the cost?
7. How long will it take? How many treatments will I need?
8. How will it interact with my other therapies and medications?
9. What research has been done on this modality?

Mr. Jones

Mr. Jones asks you whether he should stop his chemotherapy and try magnet therapy for his prostate cancer. How do you respond? What other health care team members might you collaborate with in helping Mr. Jones?

Suggested answers are at the end of the chapter.

Home Health Hints

- When taking a health history, ask the patient or caregiver about the use of complementary and alternative modalities because these may influence the effects or side effects of some prescription medications.
- Be mindful of the importance of complementary and alternative modalities to the patient’s health care belief system.
- Consider the alternative practitioner as part of the patient’s health care team.
- Discuss concerns regarding potential interactions with the registered nurse or HCP.

EVIDENCE-BASED PRACTICE

Clinical Question

How are complementary and alternative modalities used by nurses to improve health outcomes?

Evidence

The following are examples of how complementary and alternative modalities have been used by nurses to enhance health outcomes in various patient populations.

- In a recent study by Ayan et al (2013), aromatherapy with rose essential oil was...
In a randomized controlled trial of community-dwelling older people experiencing depression, music therapy was found to be effective in reducing depression and improving quality of life (Chan, Wong, Onishi, & Naidu, 2012).

Chung, Brooks, Rai, Balk, and Rai (2012) conducted a study that demonstrated meditation was effective in improving quality of life and decreasing anxiety and blood pressure.

Spiritual nursing interventions, such as active listening, creating a trusting environment, and praying with or for another were found to be effective in improving outcomes of older adults with dementia (Ennis & Kazer, 2012).

Patients with fibromyalgia experienced less pain after an animal-assisted dog therapy visit (Marcus et al., 2013).

A study by Yao, Giordani, Algase, You, and Alexander (2013) found a tai chi program decreased the fall risk status of persons diagnosed with Alzheimer’s disease.

**Implications for Nursing Practice**

Complementary and alternative modalities such as music, aromatherapy, spiritual nurse interventions, animal-assisted therapy, tai chi, and meditation can improve health outcomes in diverse patient populations. After learning these healing modalities, nurses can easily implement them in a variety of patient settings. Be sure to work within your institution’s policies and procedures.

**REFERENCES**

---

**SUGGESTED ANSWERS TO CRITICAL THINKING**

**Mr. Jones**

As with all medical treatments, it is important to support the established therapy the HCP has prescribed. Therefore, a good response might be the following: “Mr. Jones, chemotherapy is an established medical treatment for your condition. There is a lot of evidence for its effectiveness in the medical literature. If you want to supplement your therapy, there may be some other treatments you can add. I suggest that you discuss your feelings about seeking some additional treatments with your oncologist. If he agrees, then your RN and I can share some information with you about how to stay safe while trying new things.”
REVIEW QUESTIONS

1. Which of the following statements best defines a complementary modality?
   1. An alternative treatment that is used in place of a conventional treatment.
   2. A treatment that may be dangerous and should be avoided.
   3. A treatment that can be used in addition to a conventional treatment.
   4. A treatment that is used after conventional treatments have failed.

2. Which of the following therapies is most likely to use research-based interventions?
   1. Naturopathy
   2. Osteopathy
   3. Allopathy
   4. Homeopathy

3. A patient who has high blood pressure tells his nurse he has been taking a ginger supplement in addition to his prescribed medications at home. What is the best response by the nurse?
   1. “Nonprescription supplements can interact with prescription medications. You should not take it any longer.”
   2. “Ginger can be effective for hypertension. Be sure to monitor your blood pressure while you are taking it.”
   3. “Ginger is a safe supplement because it is a food. It should not interact with your medications.”
   4. “You should check with your HCP to make sure the ginger doesn’t interact with your other medications before you continue to take it.”

4. Which of the following complementary modalities are considered relaxation therapies? Select all that apply.
   1. Progressive muscle relaxation
   2. Tai chi
   3. Biofeedback
   4. Homeopathic therapies
   5. Guided imagery

5. Which of the following statements best describes the most important role of the LPN in complementary and alternative modalities?
   1. The LPN should become familiar enough to recommend at least one complementary or alternative modality.
   2. The LPN should become adept at collecting and reporting data related to patients’ use of complementary or alternative modalities.
   3. The LPN should discourage use of complementary or alternative modalities because they can interact negatively with conventional therapies.
   4. The LPN does not need to become involved in complementary and alternative modalities.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Identify the purposes of fluids and electrolytes in the body.
2. List the signs and symptoms of common fluid imbalances.
3. Predict patients who are at the highest risk for dehydration and fluid excess.
4. Identify data to collect in patients with fluid and electrolyte imbalances.
5. Describe therapeutic measures for patients with fluid and electrolyte disturbances.
6. Identify the education needs of patients with fluid imbalances.
7. Categorize common causes, signs and symptoms, and treatments for sodium, potassium, calcium, and magnesium imbalances.
8. Identify foods that have high sodium, potassium, and calcium contents.
9. Give examples of common causes of acidosis and alkalosis.
10. Compare how arterial blood gases change for each type of acid–base imbalance.
have ever wondered why you get thirsty? The body is continuously changing, and water supports these changes. Approximately 60% of a young adult’s body weight is water. Older people are less than 50% water, and infants are between 70% and 80% water. Fat cells do not contain water, so people with a higher percentage of fat cells have a lower percentage of water.

In addition to water, body fluids also contain solid substances that dissolve, called solutes. Some solutes are electrolytes and some are nonelectrolytes. Electrolytes are chemicals that can conduct electricity when dissolved in water. Examples of electrolytes are sodium, potassium, calcium, magnesium, acids, and bases; these are discussed later in this chapter. Nonelectrolytes do not conduct electricity; examples include glucose and urea.

**FLUID BALANCE**

Fluids are located in various compartments within the body. Fluid inside the cells is referred to as intracellular fluid (ICF), and fluid outside the cells is called extracellular fluid (ECF). ECF can be further divided into three types: interstitial fluid, intravascular fluid, and transcellular fluid (Fig. 6.1).

**Interstitial fluid** is the water that surrounds the body’s cells and includes lymph. **Intravascular fluid**, or blood plasma, is the fluid within arteries, veins, and capillaries. Fluids and electrolytes move between the interstitial fluid and the intravascular fluid. **Transcellular fluids** are those in specific compartments of the body, such as cerebrospinal fluid, digestive juices, and synovial fluid in joints.

**Control of Fluid Balance**

The primary control of water in the body is through pressure sensors in the vascular system that stimulate or inhibit the release of antidiuretic hormone (ADH) from the pituitary gland. A diuretic is a substance that causes the kidneys to excrete more fluid. ADH works in just the opposite way. ADH causes the kidneys to retain fluid. If fluid pressures within the vascular system decrease, more ADH is released, and water is retained. If fluid pressures increase, less ADH is released, and the kidneys eliminate more water.

**Movement of Fluids and Electrolytes in the Body**

Fluids and electrolytes move in the body by active and passive transport systems. Active transport depends on the presence of adequate cellular adenosine triphosphate (ATP) for energy. The most common examples of active transport are the sodium-potassium pumps. These pumps, located in the cell membranes, cause sodium to move out of the cells and potassium to move into the cells when needed.

In passive transport, no energy is expended specifically to move the substances. General body movements aid passive transport. The three passive transport systems are diffusion, filtration, and osmosis.

**Diffusion** is the movement of a substance from an area of higher concentration to an area of lower concentration. If you pour cream into a cup of coffee, the movement of the molecules will eventually cause the cream to be dispersed throughout the beverage. If you stir the coffee, this process occurs at a faster rate. Body movement assists passive transport, like stirring the coffee. It causes diffusion to occur at a faster rate.

**Filtration** is the movement of both water and smaller molecules through a semipermeable membrane. A semipermeable membrane works like a screen that keeps larger substances on one side and permits only smaller molecules to filter to the other side of the membrane. Filtration is promoted by hydrostatic pressure differences between areas.

**Hydrostatic pressure**, sometimes called water-pushing pressure, is the force that water exerts. In the body, filtration is important for the movement of water, nutrients, and waste products in the capillaries. The capillaries serve as semipermeable membranes allowing water and smaller substances to move from the vascular system to the interstitial fluid, but larger molecules and red blood cells remain inside the capillary walls.

**Osmosis** is the movement of water from an area of lower substance concentration to an area of higher concentration.
Fluid imbalances are common in all clinical settings. Older people are at the highest risk for life-threatening complications that can result from either fluid deficit, more commonly called dehydration, or fluid excess. Infants are at risk for fluid deficit because they take in and excrete a large proportion of their total body water each day.

**Dehydration**

Although there are several types of dehydration, only the most common type is discussed in this chapter. Dehydration occurs when there is not enough fluid in the body, especially in the blood (intravascular area).

**Pathophysiology and Etiology**

The most common form of dehydration results from loss of fluid from the body, resulting in decreased blood volume. This decrease is referred to as hypovolemia. Hypovolemia occurs when the patient is hemorrhaging or when fluids from other parts of the body are lost. For example, severe vomiting and diarrhea, severely draining wounds, and profuse diaphoresis (sweating) can cause dehydration (Box 6-1).

Hypovolemia can also occur when fluid from the intravascular space moves into the interstitial fluid space. This process is called third spacing. Examples of conditions in which third spacing is common include burns, liver cirrhosis, and extensive trauma.

As described previously in this chapter, the body initially attempts to compensate for fluid loss by a number of mechanisms. If the cause of dehydration is not resolved or the patient is not able to replace the fluid, a state of dehydration occurs.

**Prevention**

You can help prevent dehydration by identifying patients who have the highest risk for developing this condition and intervening quickly to correct the cause. High-risk patients include older adults, infants, children, and any patient with one of the conditions listed in Box 6-1. Also see “Gerontological Issues—Dehydration.”

Adequate hydration is another important intervention to help prevent dehydration. You should encourage patients to drink adequate fluids. Adults need 30 mL/kg/day of fluids. If a patient is unable to take enough fluid by mouth, alternate routes may be necessary.

**Gerontological Issues**

**Dehydration**

As a person ages, total body water decreases from 60% to 50% of total body weight. The age-related decrease in total body water is secondary to an increase in body fat and a decrease in thirst sensation. These factors increase the risk of developing dehydration.

Manifestations of dehydration in an older adult are different from typical manifestations in a younger person and may include altered mental status, lightheadedness, and syncope. These occur because a patient with hypovolemia has an inadequate circulatory volume and, therefore, oxygen supply to the brain.

**Signs and Symptoms**

Thirst is the initial symptom experienced by otherwise healthy adults in response to hypovolemia. As the percentage of water in the blood goes down, the percentage of other substances goes up, resulting in the thirst response. As the blood volume decreases,
Box 6-1  Common Causes of Dehydration

Cecostomy
Diabetes insipidus
Diarrhea
Diuretic therapy
Draining abscesses
Draining fistulas
Fever
Frequent enemas
Gastrointestinal suction
Hemorrhage
Ileostomy
Long-term nothing-by-mouth (NPO) status
Profuse diaphoresis (sweating)
Severely draining wounds
Systemic infection
Vomiting

the heart pumps the remaining blood faster but not as powerfully, resulting in a rapid, weak pulse and low blood pressure. The body pulls water into the vascular system from other areas, resulting in decreased tear formation, dry skin, and dry mucous membranes.

A dehydrated person will have poor skin turgor. Turgor is considered to be poor if the skin is pinched and a small “tent” or wrinkle remains (called tenting). A dehydrated person’s temperature increases because the body is less able to cool itself through perspiration. Temperature may not appear elevated in an older person because an older adult’s normal body temperature is often lower than a younger person’s. Urine output decreases and the urine becomes more concentrated as water is conserved. Dehydration should be considered in any adult with a urine output of less than 30 mL per hour. The urine may appear darker because it is less diluted. The patient becomes constipated as the intestines absorb more water from the feces. A major method of evaluating dehydration is weight loss. A pint of water (16 ounces) weighs approximately 1 pound. Symptoms of dehydration in older persons may be atypical (see “Gerontological Issues—Dehydration”).

**Complications**

If dehydration is not treated, lack of sufficient blood volume causes organ function to decrease and eventually fail. The brain, kidneys, and heart must be adequately supplied with blood (perfused) to function properly. The body protects these organs by decreasing blood flow to other areas. When these organs no longer receive their minimum requirements, death results.

**LEARNING TIP**

Do you remember your grandmother saying, “A pint’s a pound the world around”? It’s a great way to remember how much fluid loss is represented by each lost pound.

**Diagnostic Tests**

A patient with dehydration usually has an elevated blood urea nitrogen (BUN) level and elevated hematocrit. Both values are increased because there is less water in proportion to the solid substances being measured. The specific gravity of the urine also increases as the kidneys attempt to conserve water, resulting in a more concentrated urine.

**Therapeutic Measures**

The goals of therapeutic measures are to replace fluids and resolve the cause of dehydration. In a patient with moderate or severe dehydration, IV therapy is used. Isotonic fluids that have the same osmolarity as blood, such as normal saline, are typically administered.

**BE SAFE!**

**BE VIGILANT!** Use at least two ways to identify patients. For example, use the patient’s name and date of birth. This is done to make sure that each patient gets the correct medicine and treatment (@ The Joint Commission, 2013. Reprinted with permission).

Note: The patient’s room number or physical location is not used as an identifier.

**Nursing Process for the Patient Experiencing Dehydration**

Nurses can play a major role in identifying and caring for patients who are dehydrated.

**DATA COLLECTION.** Assess the patient for signs and symptoms of dehydration. All the classic signs and symptoms may not be present.

When assessing an older patient for skin turgor (tenting), assess the skin over the forehead or sternum. The skin over
these areas usually retains elasticity and is therefore a more reliable indicator of skin turgor. Also check mucous membranes, which should be moist.

Weight is the most reliable indicator of fluid loss or gain. A loss of 1 to 2 pounds or more per day suggests water loss rather than fat loss. The patient in the hospital setting should be weighed every day. The patient in the nursing home or home setting should be weighed at least three times a week if the patient is at risk for fluid imbalance. Weigh the patient before breakfast using the same scale each time. Intake and output (I&O) are also typically measured (see “Cultural Considerations”).

NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.
The primary nursing diagnosis and interventions for the patient with dehydration may include:

Risk for Deficient Fluid Volume or Deficient Fluid Volume related to fluid loss or inadequate fluid intake.

Expected Outcome: The patient will be adequately hydrated as evidenced by stable weight, moist mucous membranes, and elastic skin turgor.

• Monitor daily weights and I&O so problems can be detected and corrected early.
• Plan with the patient and other members of the health care team the type and timing of fluid intake. Planning with the patient increases the likelihood that the plan will be followed.
• Offer fluids often to the confused patient since he or she may not drink independently.
• Correct the underlying cause of the fluid deficit, so it does not recur.
• Be careful not to overhydrate the patient, so fluid excess does not occur.

See Box 6-2 for best practices for maintaining oral hydration in older people.

EVALUATION. The patient who is adequately hydrated will have elastic skin turgor, moist mucous membranes, and stable weight.

Patient Education
The patient, family, and significant others need to be taught the importance of reporting early signs and symptoms of dehydration to a physician or other health care provider (HCP). At home or in the nursing home, infections often cause fever and sepsis, a serious condition in which the infection invades the bloodstream. The body attempts to decrease the temperature through perspiration. The patient becomes dehydrated as a result and can become increasingly ill.

CRITICAL THINKING

Mrs. Levitt

Mrs. Levitt is a 92-year-old widow who has been living in the nursing home where you work for 4 years. Today she mentions that her urine smells bad and that her heart feels like it is beating faster than usual. You suspect that she is becoming dehydrated. You check her urine and find that it is a dark amber color and has a strong odor. Her heart rate is 98 beats per minute, blood pressure 126/74 mm Hg, respiratory rate 20 per minute, and temperature 99.2°F (37.3°C).

1. What other data should you collect, and what results do you expect?
2. Which interventions should you provide at this time?
3. How should you document your findings?
4. What other team members should be informed of your plan for Mrs. Levitt?
5. How will you know if she is improving?

Suggested answers are at the end of the chapter.

Fluid Excess
Fluid excess, sometimes called overhydration, is a condition in which a patient has too much fluid in the body. Most of the problems related to fluid excess result from too much fluid in the bloodstream or from dilution of electrolytes and red blood cells.

Pathophysiology and Etiology
The most common result of fluid excess is hypervolemia in which there is excess fluid in the intravascular space. Healthy

Cultural Considerations

Muslims who celebrate Ramadan fast for 1 month from sunup to sundown. Although the ill are not required to fast, ill Muslims may still wish to do so. Fasting may include not taking fluids and medications during daylight hours. Therefore, the nurse may need to alter times for medication administration, including intramuscular medication. Special precautions may need to be taken to prevent dehydration in Muslim patients.
adult kidneys can compensate for mild to moderate hypervolemia. The kidneys increase urinary output to rid the body of the extra fluid. Sometimes, however, the kidneys cannot keep up with the excess fluid.

Conditions that can cause excessive fluid intake are poorly controlled IV therapy, excessive irrigation of wounds or body cavities, and excessive ingestion of water. Conditions that can result in inadequate excretion of fluid include renal (kidney) failure, heart failure, and the syndrome of inappropriate antidiuretic hormone. These conditions are discussed elsewhere in this book.

**Prevention**

One of the best ways to prevent fluid excess is to avoid excessive fluid intake. For example, you should monitor the patient receiving IV therapy for signs and symptoms of fluid excess. In at-risk patients, an electronic infusion pump or a quantity-limiting device, such as a burette, should be used to control the rate of infusion.

Also monitor the amount of fluid used for irrigations. For example, when a patient’s stomach is being irrigated (gastric lavage), be sure an excessive amount of fluid is not absorbed.

**Signs and Symptoms**

The vital sign changes seen in the patient with fluid excess are the opposite of those found in patients with dehydration. The blood pressure is elevated, pulse is bounding, and respirations are increased and shallow. The neck veins may become distended, and pitting edema (excess water in tissues) in the feet and legs may be present. The skin is pale and cool. The kidneys increase urine output, and the urine appears diluted, almost like water. The patient rapidly gains weight. In severe fluid excess, the patient develops moist crackles in the lungs, dyspnea, and ascites (excess peritoneal fluid).

**Complications**

Acute fluid excess typically results in congestive heart failure. As the fluid builds up in the heart, the heart is not able to properly function as a pump. The fluid then backs up into the lungs, causing a condition known as pulmonary edema. Other major organs of the body cannot receive adequate oxygen, and organ failure can lead to death.

**Diagnostic Tests**

In the patient experiencing fluid excess, BUN and hematocrit levels tend to decrease from hemodilution. The plasma content of the blood is proportionately increased compared with the solid substances. The specific gravity of the urine also diminishes as the urinary output increases.

**Therapeutic Measures**

Once the patient’s breathing has been supported, the goal of treatment is to rid the body of excessive fluid and resolve the underlying cause of the excess. Drug therapy and diet therapy are commonly used to decrease fluid retention.

**POSITIONING.** To facilitate ease in breathing, the head of the patient’s bed should be in semi-Fowler’s or high Fowler’s position (Fig. 6.2). These positions allow greater lung expansion and thus aid respiratory effort. Once the patient has been properly positioned, oxygen therapy may be necessary.

**OXYGEN THERAPY.** Oxygen therapy is typically used to ensure adequate perfusion of major organs and to minimize dyspnea. If the patient has a history of chronic obstructive pulmonary disease, such as emphysema or chronic bronchitis,
be cautious if you need to administer more than 2 L per minute of oxygen. At higher oxygen doses, the patient may lose the stimulus to breathe and may suffer respiratory arrest. Monitor pulse oximetry and respiratory rate carefully.

**DRUG THERAPY.** Diuretics are commonly administered to rapidly rid the body of excess water. A diuretic is a drug that increases elimination by the kidneys. The drug of choice for fluid excess when the patient has adequately functioning kidneys is usually a loop diuretic such as furosemide (Lasix). Loop diuretics cause the kidneys to excrete sodium and water. Sodium (Na⁺) and water tend to move together in the body. Potassium (K⁺), another electrolyte, is also lost, which can lead to a potassium deficit, which is discussed later in this chapter.

Furosemide may be given by the oral, intramuscular, or IV route. The oral route is used most commonly for mild fluid excess. IV furosemide is administered by a registered nurse (RN) or HCP for severe fluid excess. The patient should begin diuresis within 30 minutes after receiving IV furosemide. If not, another dose is given. Strict I&O should be monitored, as well as daily weight, when a patient is receiving IV furosemide.

**DIET THERAPY.** Mild to moderate fluid restriction may be necessary, as well as a sodium-restricted diet. In collaboration with the dietitian, a HCP prescribes the specific restriction necessary, usually a 1- to 2-g sodium restriction for severe excess. Different diuretics result in differing electrolyte elimination. Specific diet therapy depends on the medications the patient is receiving and the patient’s underlying medical problems.

**Nursing Process for the Patient Experiencing Fluid Excess**

The nurse plays a pivotal role in the care of a patient with fluid excess. Prompt action is needed to prevent life-threatening complications.

**DATA COLLECTION.** Observe a patient who is at high risk for fluid excess and monitor fluid I&O carefully. If the patient is drinking adequate amounts of fluid (1500 mL per day or more) but is voiding in small amounts, the fluid is being retained by the body.

Assess for edema; if it is pitting, a finger pressed against the skin over a bony area such as the tibia leaves a temporary indentation. For patients in bed, check the sacrum for edema. For patients in the sitting position, check the feet and legs. Also assess lung sounds because excess fluid accumulation in the lungs can cause crackles (see Chapter 29).

As mentioned earlier, weight is the most reliable indicator of fluid gain. Weigh at-risk patients daily. A gain of 1 to 2 pounds or more per day indicates fluid retention even though other signs and symptoms may not be present.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.**

*Excess Fluid Volume related to excessive fluid intake or inadequate excretion of body fluid*

**Expected Outcome:** Patient will return to a normal hydration status as evidenced by return to weight that is normal for patient, absence of edema, and clear lung sounds.

- Report any increase in weight to the HCP. *Increased weight indicates fluid retention.*
- Implement fluid restriction as ordered to *reduce excess intake.* Work with the patient and RN to determine how it should be implemented. For example, if a patient is on a 1000 mL per day fluid restriction, you might plan for 150 mL with each meal, 450 mL to be given to the patient to use as he or she likes during the day and 100 mL to be used during the night. Be sure to include the patient in your planning, and remember to reserve enough fluid for swallowings medications. Post a sign in the patient’s room so other caregivers know how much fluid the patient can have.
- Administer diuretics as ordered, and monitor patient response. Be sure to monitor potassium in patients receiving potassium-losing loop or thiazide diuretics. *Diuretics promote diuresis.*
- Report urinary output below 30 mL per hour to the HCP or RN because this may signify increasing renal complications.

**EVALUATION.** If interventions have been effective, the patient will return to his or her normal weight with clear lung sounds and no edema. Many patients must remain on drug and diet therapy after hospital discharge to prevent the problem from recurring.

**Patient Education**

In collaboration with the dietitian, instruct the patient, family, or other caregiver about any fluid or sodium restrictions to prevent further problems (see “Nutrition Notes”). High-sodium foods to avoid are listed in Table 6.1.

### Nutrition Notes

**Reducing Sodium Intake**

Many foods, such as dairy products, grain products, and some vegetables, are naturally high in sodium, but the major sources of dietary sodium are salted and processed foods, including baked goods and condiments. For example, American cheese has more sodium than cheddar and cured ham has more than fresh pork.

Drinking water may contain significant amounts of sodium, particularly if it is softened or mineral water. Because of the numerous hidden sources of sodium, patients on low-sodium diets benefit from education by a dietitian.

The adequate intake (AI) of sodium is

- 1.5 g daily for adults through age 49
- 1.3 g daily for those aged 50 to 70
- 1.2 g daily for those aged 71 and older

The upper tolerable intake level (UL) for sodium is 2.3 g daily, which is contained in slightly more than a teaspoon of salt. None of these amounts applies to those losing large amounts of sweat daily or to unacclimatized persons exercising in a hot environment.
Teaching about diuretic therapy is essential to prevent electrolyte imbalances. If a potassium-losing diuretic is prescribed, teach the patient to eat foods that are high in potassium (Table 6.2). The patient’s serum potassium level must be periodically monitored by a HCP or home care nurse. If it becomes too low, an oral potassium supplement is needed.

The patient or caregiver also needs to be taught common signs and symptoms of fluid excess that should be reported to a physician or other HCP. Of special importance is weight gain. A patient at high risk for fluid excess should be weighed at least three times a week in the home or nursing home, at the same time each day, and on the same scale. Weight gain should be reported.

*Food sources of potassium ranked by milligrams of potassium per standard amount, also showing calories in the standard amount. (The adequate intake for adults is 4700 mg/day of potassium.)

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in the 2002 revision of U.S. Department of Agriculture Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.
ELECTROLYTE BALANCE

Natural minerals in food become electrolytes or ions in the body through digestion and metabolism. Electrolytes are usually measured in milliequivalents per liter (mEq/L) or in milligrams per deciliter (mg/dL).

Electrolytes are one of two types: cations, which carry a positive electrical charge, and anions, which carry a negative electrical charge. Although there are many electrolytes in the body, this chapter discusses the most important ones, including sodium (Na⁺), potassium (K⁺), calcium (Ca²⁺), and magnesium (Mg²⁺). These electrolytes are maintained in different concentrations inside the cell and outside the cell because of pumps in the cell wall (Fig. 6.3).

ELECTROLYTE IMBALANCES

At times, a patient may experience problems because of too much or too little of an electrolyte. In general, if a patient experiences a deficit of an electrolyte, the electrolyte is replaced either orally or intravenously. If the patient experiences an excess of an electrolyte, treatment focuses on getting rid of the excess, often via the kidneys. The underlying cause of the imbalance must also be treated.

The most important aspects of nursing care are preventing and assessing electrolyte imbalances. You must be vigilant in watching for signs of imbalance in high-risk patients. Serum electrolytes are measured on a regular basis. As a general rule, patients should be checked for electrolyte imbalance when there is a change in their mental state (either increased irritability or decreased responsiveness) or when muscle function changes. Patient education is another important nursing role.

Sodium Imbalances

The normal level of serum sodium is 135 to 145 mEq/L. Because sodium is the major cation in the blood, it helps maintain serum osmolarity. Therefore, sodium imbalances are often associated with fluid imbalances, described earlier in this chapter. Sodium is also important for cell function, especially in the central nervous system. The two sodium imbalances are hyponatremia (sodium deficit) and hypernatremia (sodium excess).

Hyponatremia

Hyponatremia occurs when the serum sodium level is less than 135 mEq/L.

PATHOPHYSIOLOGY AND ETIOLOGY. Many conditions can lead to either an actual or a relative decrease in sodium. In an actual decrease, the patient has inadequate intake of sodium or excessive sodium loss from the body. As the percentage of sodium in the ECF decreases, water is pulled by osmotic pressure into the cells. If the patient experiences an excess of an electrolyte, treatment focuses on getting rid of the excess, often via the kidneys. The underlying cause of the imbalance must also be treated.

The most important aspects of nursing care are preventing and assessing electrolyte imbalances. You must be vigilant in watching for signs of imbalance in high-risk patients. Serum electrolytes are measured on a regular basis. As a general rule, patients should be checked for electrolyte imbalance when there is a change in their mental state (either increased irritability or decreased responsiveness) or when muscle function changes. Patient education is another important nursing role.

CRITICAL THINKING

Mr. Peters

Mr. Peters is a 32-year-old man with a congenital heart problem. He has been recovering from congestive heart failure and fluid excess. Today his blood pressure is higher than usual, and his pulse is bounding. He is having trouble breathing and presses the call light for your assistance.

1. What should you do first when you assess Mr. Peters’s condition?
2. What questions should you ask him?
3. What objective data should you collect?
4. What should you do with your findings?

Suggested answers are at the end of the chapter.

ELECTROLYTE IMBALANCES

At times, a patient may experience problems because of too much or too little of an electrolyte. In general, if a patient experiences a deficit of an electrolyte, the electrolyte is replaced either orally or intravenously. If the patient experiences an excess of an electrolyte, treatment focuses on getting rid of the excess, often via the kidneys. The underlying cause of the imbalance must also be treated.

The most important aspects of nursing care are preventing and assessing electrolyte imbalances. You must be vigilant in watching for signs of imbalance in high-risk patients. Serum electrolytes are measured on a regular basis. As a general rule, patients should be checked for electrolyte imbalance when there is a change in their mental state (either increased irritability or decreased responsiveness) or when muscle function changes. Patient education is another important nursing role.

Sodium Imbalances

The normal level of serum sodium is 135 to 145 mEq/L. Because sodium is the major cation in the blood, it helps maintain serum osmolarity. Therefore, sodium imbalances are often associated with fluid imbalances, described earlier in this chapter. Sodium is also important for cell function, especially in the central nervous system. The two sodium imbalances are hyponatremia (sodium deficit) and hypernatremia (sodium excess).

Hyponatremia

Hyponatremia occurs when the serum sodium level is less than 135 mEq/L.

PATHOPHYSIOLOGY AND ETIOLOGY. Many conditions can lead to either an actual or a relative decrease in sodium. In an actual decrease, the patient has inadequate intake of sodium or excessive sodium loss from the body. As the percentage of sodium in the ECF decreases, water is pulled by osmotic pressure into the cells. In a relative decrease, the sodium is not lost from the body but may leave the intravascular space and move into the interstitial tissues (third spacing). Another cause of a relative decrease occurs when the plasma volume increases (fluid excess), causing a dilutional effect. The percentage of sodium compared with the fluid is diminished.

PREVENTION. Additional sodium is commonly administered to patients at high risk for hyponatremia (Box 6-3), usually by the IV route. Individuals who have high fevers or who engage in strenuous exercise or physical labor, especially in the
heat, need to replace both sodium and water. Hyponatremia is especially dangerous for the older patient.

**SIGNS AND SYMPTOMS.** Unfortunately, the signs and symptoms of hyponatremia are vague and depend somewhat on whether a fluid imbalance accompanies the hyponatremia. The patient with sodium and fluid deficits has signs and symptoms of dehydration (discussed previously). The patient with a sodium deficit and relative fluid excess has signs and symptoms associated with fluid excess.

With more severe sodium deficit, the patient experiences mental status changes, including disorientation, confusion, and personality changes. This occurs because the low sodium and decrease in osmolarity cause more “water-pushing pressure,” which causes water to collect in and around the brain and increase pressure (cerebral edema). Weakness, nausea, vomiting, and diarrhea may also occur. See “Gerontological Issues—Confusion.”

**Diagnosis.** The primary diagnostic test is a serum sodium level, which is lower than the normal value when hyponatremia is present. The serum osmolarity also decreases in patients with hyponatremia. Other laboratory results may be affected if the patient experiences an accompanying fluid imbalance. Serum chloride (Cl\(^-\)), an anion, is often depleted when sodium decreases because these two electrolytes commonly combine as NaCl (salt in solution, or saline).

**Therapeutic Measures.** Therapeutic measures focus on resolving the underlying cause of hyponatremia and replacing the lost sodium. The HCP orders IV saline for patients who have hyponatremia without fluid excess.

For patients who have a fluid excess, a fluid restriction is often ordered. Diuretics that rid the body of fluid but do not cause sodium loss may also be used. For patients with cerebral edema, steroids may be prescribed to reduce intracranial swelling. I&O are strictly monitored, and the patient is weighed daily. Also implement interventions to keep the patient safe if mental status is affected.

**Hypernatremia**

Hypernatremia occurs when the serum sodium level is above 145 mEq/L.

**Pathophysiology and Etiology.** A serum sodium increase may be an actual increase or a relative increase. In an actual increase, the patient receives too much sodium or is unable to excrete sodium, as seen in renal failure. In a relative increase, the amount of sodium does not change, but the amount of fluid in the intravascular space decreases. Therefore, the percentage of sodium (solid) is increased in relationship to the amount of plasma (water).

In mild hypernatremia, most excitable tissues, such as muscle and neurons of the brain, become more stimulated. The patient becomes irritable and has tremors. In severe cases, these tissues fail to respond.

**Prevention.** Prevention of hypernatremia is not as simple as prevention of hyponatremia. Most patients have a sodium excess as a result of an acute or chronic illness. Patients with a potential for electrolyte imbalance must always have their IV fluids carefully regulated.

**Signs and Symptoms.** Thirst is usually one of the first symptoms to appear. If you eat salty foods, such as potato chips, the amount of sodium in the body increases, and you become thirsty. Other signs and symptoms of hypernatremia are vague and nonspecific until severe excess is present. Like the patient with a sodium deficit, the patient experiencing sodium excess has mental status changes, such as agitation, confusion, and personality changes—but this time, the cause is too little fluid in the brain tissues. Seizures may also occur.

**Complications.** In severe hyponatremia, respiratory arrest or coma can lead to death. The patient who also has fluid excess may develop pulmonary edema, another life-threatening complication.

**Word Building.** Intra-—within + Cranial—cranium (skull)
At first, muscle twitches and unusual contractions may be present. Later, skeletal muscle weakness occurs that can lead to respiratory failure if it affects the diaphragm. If fluid deficit or fluid excess accompanies the hypernatremic state, the patient also has signs and symptoms associated with these imbalances.

**COMPLICATIONS.** A patient with severe hypernatremia may become comatose or have respiratory arrest as skeletal muscles weaken.

**DIAGNOSTIC TESTS.** The most reliable diagnostic test is the serum sodium level, which indicates an increase above the normal level. Serum osmolarity may also increase. If the patient has a fluid imbalance, other laboratory values, such as BUN, hematocrit, and urine specific gravity, are also affected (see earlier discussion).

**THERAPEUTIC MEASURES.** If a fluid imbalance accompanies hypernatremia, it is treated first. For example, fluid replacement without sodium in a patient with dehydration should correct a relative sodium excess. If the kidneys are not excreting adequate amounts of sodium, diuretics may help if the kidneys are functional. If the kidneys are not functioning properly, dialysis may be ordered (see Chapter 37). I&O and daily weights are strictly monitored.

The cause of hypernatremia is also treated in an attempt to prevent further episodes of this imbalance. For some patients, a sodium-restricted diet is prescribed.

**Potassium Imbalances**

Potassium is the most common electrolyte in the ICF compartment. Therefore, only a small amount, 3.5 to 5 mEq/L, is found in the bloodstream. Small changes in this laboratory value cause major changes in the body.

Potassium is especially important for cardiac muscle, skeletal muscle, and smooth muscle function. If the serum potassium level falls, the body attempts to compensate by moving potassium from the cells into the bloodstream.

The two potassium imbalances are **hypokalemia** (potassium deficit) and **hyperkalemia** (potassium excess). Hypokalemia is the most commonly occurring imbalance.

**Hypokalemia**

Hypokalemia occurs when the serum potassium level falls below 3.5 mEq/L.

**PATHOPHYSIOLOGY AND ETIOLOGY.** Most cases of hypokalemia result from inadequate intake of potassium or excessive loss of potassium through the kidneys. Hypokalemia most often occurs as a result of medications. Potassium-losing diuretics (e.g., furosemide [Lasix]), digitalis preparations (e.g., digoxin [Lanoxin]), and corticosteroids (e.g., prednisone [Deltasone]) are examples of drugs that cause increased excretion of potassium from the body. Potassium may also be lost through the gastrointestinal (GI) tract, which is rich in potassium and other electrolytes. Severe vomiting, diarrhea, and prolonged GI suction cause hypokalemia (see “Patient Perspective”). Major surgery and hemorrhage can also lead to potassium deficit.

**DIAGNOSTIC TESTS.** The most reliable diagnostic test is the serum potassium level, which indicates an increase above the normal level. Serum osmolarity may also increase. If the patient has a fluid imbalance, other laboratory values, such as BUN, hematocrit, and urine specific gravity, are also affected (see earlier discussion).

**THERAPEUTIC MEASURES.** If a fluid imbalance accompanies hypernatremia, it is treated first. For example, fluid replacement without sodium in a patient with dehydration should correct a relative sodium excess. If the kidneys are not excreting adequate amounts of sodium, diuretics may help if the kidneys are functional. If the kidneys are not functioning properly, dialysis may be ordered (see Chapter 37). I&O and daily weights are strictly monitored.

The cause of hypernatremia is also treated in an attempt to prevent further episodes of this imbalance. For some patients, a sodium-restricted diet is prescribed.

**Potassium Imbalances**

Potassium is the most common electrolyte in the ICF compartment. Therefore, only a small amount, 3.5 to 5 mEq/L, is found in the bloodstream. Small changes in this laboratory value cause major changes in the body.

Potassium is especially important for cardiac muscle, skeletal muscle, and smooth muscle function. If the serum potassium level falls, the body attempts to compensate by moving potassium from the cells into the bloodstream.

The two potassium imbalances are **hypokalemia** (potassium deficit) and **hyperkalemia** (potassium excess). Hypokalemia is the most commonly occurring imbalance.

**Hypokalemia**

Hypokalemia occurs when the serum potassium level falls below 3.5 mEq/L.

**PATHOPHYSIOLOGY AND ETIOLOGY.** Most cases of hypokalemia result from inadequate intake of potassium or excessive loss of potassium through the kidneys. Hypokalemia most often occurs as a result of medications. Potassium-losing diuretics (e.g., furosemide [Lasix]), digitalis preparations (e.g., digoxin [Lanoxin]), and corticosteroids (e.g., prednisone [Deltasone]) are examples of drugs that cause increased excretion of potassium from the body. Potassium may also be lost through the gastrointestinal (GI) tract, which is rich in potassium and other electrolytes. Severe vomiting, diarrhea, and prolonged GI suction cause hypokalemia (see “Patient Perspective”). Major surgery and hemorrhage can also lead to potassium deficit.

**PREVENTION.** Most patients having major surgery receive potassium supplements in their IV fluids to prevent hypokalemia. For patients receiving drugs known to cause hypokalemia, foods high in potassium may prevent a deficit (see Table 6.2). Patients receiving digitalis must be closely monitored because digitalis can cause hypokalemia, which in turn can enhance the action of digitalis and cause digitalis toxicity.

**SIGNS AND SYMPTOMS.** Many body systems are affected by a potassium imbalance. Muscle cramping or muscle fatigue can occur with either a deficit or an excess of potassium. Vital signs change because the respiratory and cardiovascular systems need potassium to function properly. Diminished skeletal muscle activity results in shallow, ineffective respirations. The pulse is typically weak, irregular, and thready because the heart muscle is depleted of potassium. A major danger is an irregular heartbeat (dysrhythmia), which can lead to cardiac arrest. Orthostatic (postural) hypotension may also be present.

---

**Patient Perspective**

Patricia

I take hydrochlorothiazide for my high blood pressure. Since it can make me lose potassium, I also take a potassium supplement. So I thought I was all set. But recently I ate something that did not agree with me, and I had diarrhea for a couple of days. One morning as I was driving to work, I felt so weak it made me frightened. I drove back home and asked my husband to drive me to work. I arrived safely, but as I walked down the hallway, I again felt so weak I had to sit down. I felt like I could not put one foot in front of the other. I kept thinking, “This is all in my head.” I decided maybe I was dehydrated from the diarrhea, so I drank a bottle of Gatorade and a glass of orange juice. Slowly I began to feel a bit better, and I made it through the day. After work I had to take my daughter to the doctor, so I asked about my symptoms. I was sent to the lab where I had my potassium level checked, and it was 3.11 Normal is 3.5 to 5 mEq/L. Mine must have been even lower before I drank the juice and Gatorade. I learned that I probably lost a lot of potassium because of the diarrhea. I also learned that low potassium made my muscles weak and could have affected my heart function. Next time I have diarrhea, I plan to call my doctor.
The nervous system is usually affected as well. The patient experiences changes in mental status followed by lethargy. The motility of the GI system is slowed, causing nausea, vomiting, abdominal distention, and constipation. Vomiting may further increase potassium loss.

COMPLICATIONS. If not corrected, hypokalemia can result in death from dysrhythmia, respiratory failure and arrest, or coma. The patient must be treated promptly before these complications occur.

DIAGNOSTIC TESTS. The primary laboratory test is to obtain a serum potassium level. The patient’s electrocardiogram (ECG) may show cardiac dysrhythmias associated with potassium deficit. In addition to a decrease in the serum potassium level, the patient may have an acid–base imbalance known as metabolic alkalosis, which commonly accompanies hypokalemia. In metabolic alkalosis, the serum pH of the blood increases (>7.45) so that the blood is more alkaline than usual. Acid–base imbalances are discussed later in this chapter.

THERAPEUTIC MEASURES. The goal of treatment is to replace potassium in the body and resolve the underlying cause of the imbalance. For mild to moderate hypokalemia, oral potassium supplements are given.

For severe hypokalemia, IV potassium supplements are given. Because the kidneys eliminate excess potassium, potassium should be administered only after the patient has voided. Potassium is a potentially dangerous drug, especially when administered intravenously. In too high a concentration, it causes cardiac arrest. Only IV solutions that are premixed and carefully labeled should be used. Potassium is never given by IV push. The patient’s laboratory values must be monitored carefully to prevent giving too much potassium.

Teach the patient about the side effects of oral potassium and precautions associated with potassium administration. Box 6-4 summarizes the precautions the patient should be aware of when taking oral potassium supplements.

Hyperkalemia

Hyperkalemia is a condition in which the serum potassium level exceeds 5 mEq/L. It is rare in a person with healthy kidneys.

PATHOPHYSIOLOGY AND ETIOLOGY. Hyperkalemia may result from an actual increase in the amount of total body potassium or from the movement of intracellular potassium into the blood. Overuse of potassium-based salt substitutes or excessive intake of oral or IV potassium supplements can cause hyperkalemia. Use of potassium-sparing diuretics (e.g., spironolactone [Aldactone]) may also contribute to hyperkalemia. Patients with renal failure are at risk for hyperkalemia because the kidneys cannot excrete potassium.

Movement of potassium from the cells into the blood and other ECF is common in massive tissue trauma and metabolic acidosis. Metabolic acidosis is an acid–base imbalance commonly seen in patients with uncontrolled diabetes mellitus. Acid–base imbalances are discussed later in this chapter.

PREVENTION. For patients receiving potassium supplements, hyperkalemia can be prevented by monitoring serum electrolyte values and the patient’s signs and symptoms and adjusting the dose accordingly.

SIGNS AND SYMPTOMS. Most cases of hyperkalemia occur in patients who are hospitalized or those undergoing therapeutic measures for a chronic condition. The classic manifestations are muscle twitches and cramps, later followed by profound muscular weakness; increased GI motility (diarrhea); slow, irregular heart rate; and decreased blood pressure.

COMPLICATIONS. Cardiac dysrhythmias and respiratory failure can occur in severe hyperkalemia, causing death.

DIAGNOSTIC TESTS. In addition to an elevated serum potassium level, an irregular ECG is associated with hyperkalemia. If the patient also has metabolic acidosis, the serum pH falls below 7.35.

THERAPEUTIC MEASURES. For mild, chronic hyperkalemia, dietary limitation of potassium-rich foods may be helpful.

Box 6-4 Tips for Patients Taking Oral Potassium Supplements

- Do not substitute one potassium supplement for another.
- Dilute powders and liquids in juice or other desired liquid to improve taste and to prevent gastrointestinal irritation. Follow manufacturer’s recommendations for the amount of fluid to use for dilution, most commonly 4 oz per 20 mEq of potassium.
- Do not drink diluted solutions until mixed thoroughly.
- Do not crush potassium tablets, such as Slow-K or K-tab tablets. Read manufacturer’s directions regarding which tablets can be crushed.
- Take slow-release tablets with 8 oz of water to help them dissolve.
- Do not take potassium supplements if taking potassium-sparing diuretics such as spironolactone or triamterene.
- Do not use salt substitutes containing potassium unless prescribed by the HCP.
- Take potassium supplements with meals.
- Report adverse effects, such as nausea, vomiting, diarrhea, and abdominal cramping, to the HCP.
- Have frequent laboratory testing for potassium levels as recommended by the HCP.

WORD BUILDING

alkalosis: alkal–alkaline + osis–condition
acidosis: acid–acidic + osis–condition
Potassium supplements are discontinued, and potassium-losing diuretics are given to patients with healthy kidneys. For patients with renal problems, a cation exchange resin, such as sodium polystyrene sulfonate (Kayexalate), is administered either orally or rectally. This drug releases sodium and absorbs potassium for excretion through the feces and out of the body.

In cases in which cellular potassium has moved into the bloodstream, administration of glucose and insulin can facilitate the movement of potassium back into the cells. During treatment of moderate to severe hyperkalemia, the patient should be in the hospital on a cardiac monitor.

**Calcium Imbalances**

Calcium is a mineral that is primarily stored in bones and teeth. A small amount is found in ECF. The normal value for serum calcium is 9 to 11 mg/dL, or 4.5 to 5.5 mEq/L. Minimal changes in serum calcium levels can have major negative effects in the body.

Calcium is needed for the proper function of excitable tissues, especially cardiac muscle. The two calcium imbalances are hypocalcemia and hypercalcemia.

**Hypocalcemia**

Hypocalcemia occurs when the serum calcium level falls below 9 mg/dL, or 4.5 mEq/L.

**PATHOPHYSIOLOGY AND ETIOLOGY.** Although calcium deficit can be acute or chronic, most patients develop hypocalcemia slowly as a result of chronic disease or poor intake. The woman who is postmenopausal is most at risk for hypocalcemia. As a woman ages, calcium intake typically declines. The parathyroid glands recognize this decrease and stimulate bone to release some of its stored calcium into the blood for replacement. The result is a condition known as osteoporosis, in which bones become porous and brittle and fracture easily. The woman who is postmenopausal has a decreased level of estrogens, hormones that help prevent bone loss in the younger woman. Immobility or decreased mobility also contributes to bone loss in many patients. The patients at highest risk for osteoporosis are thin, petite, Caucasian women.

Hypocalcemia can also result from inadequate absorption of calcium from the intestines, as seen in patients with Crohn’s disease, a chronic inflammatory bowel disease. Insufficient intake of vitamin D prevents calcium absorption as well. Conditions that interfere with the production of parathyroid hormone, such as partial or complete surgical removal of the thyroid or parathyroids, can also cause hypocalcemia.

Finally, patients with hyperphosphatemia (usually those with renal failure) often experience hypocalcemia. Calcium and phosphate have an inverse relationship. When one of these electrolytes increases, the other tends to decrease and vice versa.

---

**EVIDENCE-BASED PRACTICE**

**Clinical Question**

Are there problems associated with taking too much supplemental calcium?

**Evidence**

Studies conducted in Sweden discovered that women who had long-term calcium intakes from all sources above 1400 mg/day had higher death rates from all causes (Michaëllson, Melhus, Lemming, Wolk, & Byberg, 2013).

**Implications for Nursing Practice**

When patients take calcium supplements, teach them how to calculate their total calcium intake and that too much calcium can be as harmful as too little calcium. Teach patients to consult with their providers before beginning calcium supplements.

**REFERENCE**

---

Vitamin D supplementation may be required in addition to calcium for patients whose sun exposure is limited. The sun’s ultraviolet light causes the skin to manufacture vitamin D.

**SIGNS AND SYMPTOMS.** Chronic hypocalcemia is usually not diagnosed until the patient breaks a bone, usually a hip. Acute hypocalcemia, which can occur after surgery or in patients with acute pancreatitis, has several signs and symptoms. These include increased and irregular heart rate, mental status changes, hyperactive deep tendon reflexes, and increased GI motility, including diarrhea and abdominal cramping. Two classic signs that can be used to assess for hypocalcemia are Trousseau’s sign and Chvostek’s sign.

To test for Trousseau’s sign, inflate a blood pressure cuff around the patient’s upper arm for 1 to 4 minutes. In a patient with hypocalcemia, the hand and fingers become spastic and go into palmar flexion (Fig. 6.4). A positive Chvostek’s sign
test also indicates calcium deficit. To test for this sign, tap the face just below and in front of the ear. Facial twitching on that side of the face indicates a positive test (Fig. 6.5). The Trousseau’s sign is more specific for hypocalcemia than Chvostek’s sign.

**LEARNING TIP**

You can remember which sign is Chvostek’s sign because it causes spasm near the cheek.

**COMPLICATIONS.** In severe hypocalcemia, neuromuscular irritability can lead to tetany, or continuous muscle contraction. The patient may have a sudden laryngospasm that will stop air from entering the lungs. Seizures, respiratory failure, or cardiac failure can occur and lead to death if not aggressively treated.

**DIAGNOSTIC TESTS.** The patient with hypocalcemia has a lowered serum calcium level and an abnormal ECG. The parathyroid hormone level may be increased as it attempts to stimulate bone to release more calcium into the blood.

**THERAPEUTIC MEASURES.** In addition to treating the cause of hypocalcemia, calcium is replaced. For mild or chronic hypocalcemia, oral calcium supplements with or without vitamin D are given. Calcium supplements should be administered 1 to 2 hours after meals to increase intestinal absorption. Be sure to check compatibility when administering calcium with other medications.

For patients with acute or severe hypocalcemia, IV calcium gluconate or calcium chloride is given. When a patient has had thyroid or parathyroid surgery, there is a danger that parathyroid hormone will be decreased, causing serum calcium to drop. IV calcium must be readily available for emergency use if signs of hypocalcemia occur.

For patients with hyperphosphatemia, usually those with renal failure, aluminum hydroxide is used to bind the excess phosphate for elimination via the GI tract. As the phosphate decreases, the serum calcium level begins to approach normal levels.

Diet therapy is an important part of treatment. Teach the patient, family, or other caregiver which foods are high in calcium (Table 6.3). Many foods today are fortified with calcium. Vitamin D foods are also encouraged, especially milk and other dairy products. For patients experiencing difficulty digesting dairy products and those who choose not to use dairy products, special attention must be paid to including other dietary calcium sources in the diet.

**CRITICAL THINKING**

_Mrs. Wright_

Mrs. Wright is a 77-year-old petite Caucasian woman who lives alone at home. She is on a fixed income and rarely eats calcium-rich foods. She recently fell and broke her hip. After surgery, she returned home under the care of a home health agency.

1. What made the patient at high risk for a fracture?
2. What would you expect her serum calcium level to have been before the fall?
3. What patient teaching related to diet and calcium supplements should the home health nurse include during his or her home visits?
4. In addition to a nurse, what other home health team members might be helpful for Mrs. Wright?

_Suggested answers are at the end of the chapter._

**Hypercalcemia**

Hypercalcemia occurs when the serum calcium is above 11 mg/dL, or 5.5 mEq/L.
PATHOPHYSIOLOGY AND ETIOLOGY. Chronic hypercalcemia can result from excessive intake of calcium or vitamin D, renal failure, hyperparathyroidism, cancers, and overuse or prolonged use of thiazide diuretics, such as hydrochlorothiazide (HydroDIURIL). Acute hypercalcemia can occur as an emergency in patients with invasive or metastatic cancers, especially cancers of the blood or bone.

PREVENTION. Although many causes of increased calcium cannot be prevented, a person receiving calcium supplements should be monitored carefully. Some patients believe that if two or three tablets a day are helpful, consuming twice that much will help even more. The result can be serum calcium excess. Educating the public about the proper amount of calcium needed each day and the danger of too much calcium is very important.

*Both calcium content and bioavailability should be considered when selecting dietary sources of calcium. Some plant foods have calcium that is well absorbed, but the large quantity of plant foods that would be needed to provide as much calcium as in a glass of milk may be unachievable for many. Many other calcium-fortified foods are available, but the percentage of calcium that can be absorbed is unavailable for many of them.  
†Calcium sulfate and magnesium chloride.  
Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in the 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

SIGNS AND SYMPTOMS. Patients who have mild hypercalcemia or a slowly progressing calcium increase may have no obvious signs and symptoms. However, acute hypercalcemia is associated with increased heart rate and blood pressure, skeletal muscle weakness, and decreased GI motility.

COMPLICATIONS. In some cases, the patient may experience renal or urinary calculi (stones) resulting from the buildup of calcium. In more severe cases of acute hypercalcemia, the...
patient may experience respiratory failure caused by profound muscle weakness or heart failure caused by dysrhythmias.

**THERAPEUTIC MEASURES.** Patients with severe hypercalcemia should be hospitalized and placed on a cardiac monitor. Unless contraindicated by other conditions, the primary treatment is to give large amounts of fluids and promote diuresis. Saline infusions are the most useful solutions to promote renal excretion of calcium.

The HCP also discontinues thiazide diuretics if the patient was receiving them and prescribes diuretics that promote calcium excretion, such as furosemide (Lasix). Drugs that slow calcium movement from bones to the blood may also be used, such as pamidronate (Aredia), zoledronic acid (Zometa), or calcitonin.

If hypercalcemia is so severe that cardiac problems are present, hemodialysis, peritoneal dialysis, or ultrafiltration may be necessary to cleanse the blood of excess calcium. (See Chapter 37 for discussion of these procedures.)

**Magnesium Imbalances**

Magnesium and calcium work together for the proper functioning of excitable cells, such as cardiac muscle and nerve cells. Therefore, an imbalance of magnesium is usually accompanied by an imbalance of calcium.

The normal value for serum magnesium is 1.5 to 2.5 mEq/L. The magnesium imbalances are called hypomagnesemia and hypermagnesemia.

**Hypomagnesemia**

Hypomagnesemia occurs when the serum magnesium level falls below 1.5 mEq/L. It results from either a decreased intake or an excessive loss of magnesium. Causes of inadequate intake include malnutrition and starvation diets. Patients with severe diarrhea and Crohn’s disease are unable to absorb magnesium in the intestines.

One of the major causes of hypomagnesemia is alcoholism, which causes both a decreased intake and an increased renal excretion of magnesium. Certain drugs, such as loop and osmotic diuretics, aminoglycosides (e.g., gentamicin), and some anticancer agents (e.g., cisplatin), can increase renal excretion of magnesium.

The signs and symptoms of hypomagnesemia are similar to those for hypocalemia, including positive Trousseau’s and Chvostek’s signs, described earlier in this chapter.

The goal of management is to treat the underlying cause and replace magnesium in the body. Magnesium sulfate is administered intravenously. If the serum calcium is also low, calcium replacement is prescribed. The patient is placed on a cardiac monitor because of magnesium’s effect on the heart. Life-threatening dysrhythmias can lead to cardiac failure and arrest.

**ACID–BASE BALANCE**

The cells of the body function best when the body fluids and electrolytes are within a narrow range. Hydrogen (H⁺) is another ion that must stay within its normal limits. The amount of hydrogen determines whether a fluid is an acid or base.

An acid is a substance that releases a hydrogen ion. The stronger the acid, the more hydrogen ions are released. A common acid in the body is hydrochloric acid (HCl), which is found in the stomach. A base is a substance that binds hydrogen. A common base in the body is bicarbonate (HCO₃⁻). Alkali is another word for base.

**Sources of Acids and Bases**

Acids and bases are formed in the body as part of normal metabolic processes. Acids are formed as end products of glucose, fat, and protein metabolism. These are called fixed acids because they do not change once they are formed. A weak acid, carbonic acid, can be formed when the carbon dioxide resulting from cellular metabolism combines with water. This acid can change to bicarbonate (a base) and hydrogen and therefore is not a fixed acid.

The ECF maintains a delicate balance between acids and bases. The strength of the acids and bases can be measured by pH. The pH of a solution can vary from 0 to 14, with 7 being neutral, 0 to 6.99 being acid, and 7.01 to 14 being base, also called alkaline. The normal serum pH level is 7.35 to 7.45, which is slightly alkaline. It must remain in an extremely narrow range to sustain life. An arterial pH lower than 6.9 or higher than 7.8 is usually fatal.

**LEARNING TIP**

The word “acid” has fewer letters and lower numbers (<7.35). “Alkaline” has more letters and higher numbers (>7.45).
Control of Acid–Base Balance

As discussed in the sections on fluid and electrolyte balance, the body has several ways in which it tries to compensate for changes in the serum pH. Three major mechanisms are used: cellular buffers, the lungs, and the kidneys.

Cellular buffers are the first to attempt a return of the pH to its normal range. Examples of cellular buffers are proteins, hemoglobin, bicarbonate, and phosphates. These buffers act as a type of sponge to “soak up” extra hydrogen ions if there are too many (too acidic) or release hydrogen ions if there are not enough (too alkaline).

The lungs are the second line of defense to restore normal pH. When the blood is too acidic (pH is decreased), the lungs “blow off” additional carbon dioxide through rapid, deep breathing. This reduces the amount of carbon dioxide available to make carbonic acid in the body. If the blood is too alkaline (pH is increased), the lungs try to conserve carbon dioxide through shallow respirations.

The kidneys are the slowest to respond to changes in serum pH, taking as long as 24 to 48 hours to assist with compensation. The kidneys help in a number of ways, including regulating the amount of bicarbonate (base) that is kept in the body. If the serum pH lowers and becomes too acidic, the kidneys reabsorb additional bicarbonate rather than excreting it so that it can help neutralize the acid. If the serum pH increases and becomes too alkaline, the kidneys excrete additional bicarbonate to get rid of the extra base. The kidneys also buffer pH by forming acids and ammonium (a base).

Acidosis or alkalosis that is corrected for by the body is referred to as compensated. The pH is returned to normal or near normal, but the gases that monitor acid–base balance (PCO₂ and HCO₃⁻) are abnormal.

ACID–BASE IMBALANCES

Acid–base imbalances are caused by a number of acute and chronic illnesses or conditions. The primary treatment for each of the imbalances is to manage the underlying cause, which corrects the imbalance. The role of the nurse is to identify patients at risk and monitor laboratory test values for significant changes.

The laboratory tests that are used to evaluate acid–base balance are called arterial blood gases (ABGs). As the name implies, the blood sample that is analyzed must be from an artery rather than a vein. The femoral, brachial, and radial arteries are most often used to obtain the sample. Table 6.4 lists ABG values and what they indicate.

The two broad types of acid–base imbalance are acidosis and alkalosis. Each of these imbalances can occur suddenly, which is called an acute imbalance, or develop over a long period, referred to as a chronic imbalance.

When the serum pH level falls below 7.35, the patient has acidosis because the blood becomes more acidic than normal. Too much acid or too little base in the body causes acidosis. Acidosis can be divided into two types: respiratory and metabolic. Respiratory acidosis is caused by problems occurring in the respiratory system. Metabolic acidosis is the result of problems in the rest of the body.

When the serum pH level increases above 7.45, the patient has alkalosis because the blood becomes more alkaline or basic. Alkalosis is caused by too little acid in the body or too much base. It can also be divided into two types: respiratory alkalosis and metabolic alkalosis.

</table>
Progressing from confusion and lethargy to stupor and coma if not treated. The lungs are not able to get rid of excess carbon dioxide. Instead respirations become more depressed and shallow as muscle weakness worsens.

Treatment of respiratory acidosis is aggressive management of the underlying respiratory problem, discussed in the respiratory unit (Unit Seven) of this text.

Metabolic Acidosis

Metabolic acidosis can result from too much acid in the body (usually fixed acids) or too little bicarbonate in the body. Uncontrolled diabetes mellitus and end-stage renal failure are the two most common causes of metabolic acidosis resulting from increased fixed acids.

The GI tract is rich in bicarbonate. Patients experiencing severe diarrhea or prolonged intestinal suction are at high risk for metabolic acidosis as a result of bicarbonate (base) loss. The serum pH decreases as the bicarbonate level decreases (see Table 6.4). As mentioned earlier in the discussion on hyperkalemia, serum potassium tends to increase in the presence of metabolic acidosis. Excess hydrogen in the ECF moves into the cells in exchange for potassium, which leaves the cells and enters the blood. In a sense, this is a way of compensating for the acidic state.

The signs and symptoms are similar to those associated with respiratory acidosis, with the exception of the respiratory pattern. To help compensate for the acidic state, the lungs get rid of extra carbon dioxide through Kussmaul’s respirations. Kussmaul’s respirations are deep and rapid and can occur only in patients with healthy lungs.

The treatment for the patient with metabolic acidosis is management of the underlying disease or condition. Information about disease management, such as management of diabetes, is found elsewhere in this book.

Respiratory Alkalosis

Respiratory alkalosis occurs when there is excessive loss of carbon dioxide through hyperventilation. Patients may hyperventilate when they are severely anxious or fearful. Patients who hyperventilate have rapid shallow respirations, are lightheaded, and may become confused. The heart rate increases and the pulse becomes weak and thready. The serum pH is increased and the PaCO₂ is very low. Mechanical ventilation can also cause respiratory alkalosis, and it can occur as a result of being at high altitudes. You may have experienced this while deep breathing during a pulmonary examination.

Respiratory alkalosis is treated by having patients slow their breathing, breathe through pursed lips, or cover the mouth and one nostril to reduce airflow. The underlying cause must also be treated.

Metabolic Alkalosis

Metabolic alkalosis results from excessive ingestion of bicarbonate or other bases into the body or loss of acids from the body. Overuse or abuse of antacids or baking soda (sodium bicarbonate) can lead to metabolic alkalosis. Because the stomach contains HCL, prolonged vomiting or gastric suction can cause loss of acid and also lead to metabolic alkalosis.

The serum pH is increased, as is bicarbonate. As discussed under potassium imbalances, the serum potassium decreases. Hydrogen from the ICF moves into the blood in exchange for potassium, which moves from the blood into the cells. This is one way that the body works to keep an acid–base balance. Hypocalcemia may also accompany hypokalemia.

The signs and symptoms of metabolic alkalosis are related to hypokalemia and hypocalcemia rather than the alkalotic state itself. Treatment involves identifying the underlying cause and managing it as quickly as possible.

Compensation

If the respiratory system is compensating for metabolic acidosis, the PCO₂ will be decreased to return the pH level to normal or near normal. In a similar fashion, if there is metabolic alkalosis, the breathing pattern will change to conserve CO₂ and restore the pH level. In chronic respiratory conditions, the kidneys conserve HCO₃⁻ to buffer in the case of respiratory acidosis and excrete HCO₃⁻ in cases of chronic respiratory alkalosis.

## SUGGESTED ANSWERS TO CRITICAL THINKING

### Mrs. Levitt

1. Check her weight and compare it with her previous weights. Dehydration is associated with weight loss. Monitor mental status for disorientation. Check skin turgor for tenting. Continue to monitor vital signs.

2. Encourage increased fluid intake; notify the RN or HCP if Mrs. Levitt is unable to take in additional fluids or if the fluids do not normalize assessment findings.

3. S: “My urine smells bad, and my heart is beating fast.”

   O: Pt’s urine is dark amber and strong smelling.

   Weight 112# (baseline 116#); skin tenting present.

   VS: P 98 beats per minute, BP 126/74 mm Hg, RR 20 per minute, T 99.2. Fluids encouraged. RN notified.

4. Notify the RN but also the nursing assistant, who can help with encouraging fluids during and between meals as well as monitoring skin condition. Contact the dietary department to obtain beverages she prefers that do not contain caffeine.

Continued
5. Watch for her weight to return to her normal, for her skin to feel more elastic, and for her urine to appear more dilute. Vital signs should also return to baseline.

**Mr. Peters**
1. Raise the head of the bed to assist breathing.
2. Using the **WHAT’S UP?** format as a guide, ask the following questions: How are you feeling? Did anything aggravate your symptoms? When did your symptoms begin? On a scale of 0 to 10, how difficult is your breathing? Are you having any problems besides shortness of breath? What do you think might be happening? (If the patient is too dyspneic to answer, do not ask many questions.)
3. Check breath sounds for crackles, observe for dependent edema and ascites, observe for distended neck veins, assess skin for color and temperature, check weight and compare with previous weight, and monitor I&O. Continue to monitor vital signs.
4. Notify RN or HCP of your findings.

**Mrs. Wright**
1. The patient is at high risk for osteoporosis, and thus fracture, because she is an older, petite, Caucasian woman. In addition, she does not get much calcium in her diet.
2. Her serum calcium levels would be low or low normal because the body will mobilize calcium in the bones in an attempt to maintain serum calcium levels.
3. Teach her about consuming foods high in calcium, the need to be compliant with taking her calcium supplements, and to take the supplements 1 to 2 hours after meals for best absorption by the body.
4. She would benefit from physical therapy for ambulation and strengthening, occupational therapy for an evaluation of her home environment and possible assistive devices, and a dietitian for dietary counseling. Caution her to avoid taking excessive calcium supplements because that can also be harmful.

**REVIEW QUESTIONS**

1. Which of the following are functions of sodium in the body? **Select all that apply.**
   1. Maintenance of serum osmolarity
   2. Formation of bones and teeth
   3. Control of bronchodilation
   4. Control of serum glucose
   5. Maintenance of cellular function

2. A 93-year-old patient with diarrhea and dehydration is admitted to the hospital from an extended care facility. For which of the following symptoms of dehydration should the nurse assess?
   1. Pale-colored urine, bradycardia
   2. Disorientation, poor skin turgor
   3. Decreased hematocrit, hypothermia
   4. Lung congestion, abdominal discomfort

3. Which patient is most at risk for fluid excess?
   1. An infant with pneumonia
   2. A teen with multiple injuries following an automobile accident
   3. A middle-aged man who has just had surgery
   4. An older adult patient receiving IV therapy

4. What is the most reliable way to monitor a patient’s fluid status?
   1. Intake and output
   2. Skin turgor
   3. Daily weights
   4. Lung sounds

5. When caring for a patient with fluid excess, which of the following interventions will best help relieve respiratory distress?
   1. Elevate the head of the bed.
   2. Encourage the patient to cough and deep breathe.
   3. Increase fluids to promote urine output.
   4. Perform percussion and postural drainage.

6. A patient is being discharged following hospitalization for fluid imbalance. Which instruction by the nurse should take priority?
   1. “Weigh yourself at the same time every day and report changes.”
   2. “Call your doctor immediately if you feel weak or fatigued.”
   3. “Drink eight glasses of water a day.”
   4. “Measure everything you drink, and measure how much you urinate each day.”

7. A patient is being treated for hypokalemia. When evaluating response to potassium replacement therapy, which of the following assessment findings should the nurse observe for?
   1. Improving visual acuity
   2. Worsening constipation
   3. Decreasing serum glucose
   4. Increasing muscle strength
Chapter 6  Nursing Care of Patients With Fluid, Electrolyte, and Acid–Base Imbalances

8. A patient is being placed on a potassium-losing diuretic. Which foods are high in potassium and should be recommended to the patient by the nurse? Select all that apply.
1. Bread
2. Potato
3. Tomato juice
4. Banana
5. Gelatin

9. Which patient is at risk for respiratory acidosis?
1. The patient with uncontrolled diabetes mellitus
2. The patient with chronic pulmonary disease
3. The patient who is very anxious
4. The patient who overuses antacids

10. Which pH value represents acidosis?
1. 7.26
2. 7.35
3. 7.4
4. 7.49

Answers can be found in Appendix C.

KEY TERMS

cannula (KAN-yoo-lah)
extravasation (eks-TRAH-vah-ZAY-shun)
hematoma (HEE-muh-TOH-mah)
infiltration (in-fil-TRAY-shun)
intravenous (IN-trah-VEE-nuss)
macrodrop (MACK-roh-DROP)
microdrop (MIKE-roh-DROP)
parenteral (pah-REN-ter-ul)
phlebitis (flo-BYE-tis)

LEARNING OUTCOMES

1. Discuss how the practice of intravenous (IV) therapy is regulated.
2. List indications for IV therapy.
3. Identify common veins used for peripheral IV (PIV) therapy.
4. Describe factors that influence the condition, size, and long-term use of veins.
5. List the steps in the procedure for inserting an IV cannula.
6. Describe methods for locating and/or visualizing difficult veins.
7. Plan nursing interventions to prevent IV therapy complications.
8. Identify common complications associated with IV therapy.
9. Calculate flow and drip rates for IV solutions.
10. Differentiate characteristics of isotonic, hypertonic, and hypotonic solutions.
11. Explain the differences between peripheral and central venous access devices.
12. Describe various types of central venous access devices.
Mrs. Brown, 85 years old, is admitted to the hospital with weight loss of 6% of her total body weight due to gastritis and diarrhea. Her blood pressure is 102/80, pulse is 96 beats per minute, and respirations are 14 per minute. Her physical assessment shows decreased skin turgor over the sternum; dry, cracked lips; and a weak, thready pulse. The health care provider (HCP) has ordered an IV of 5% dextrose and 0.45% sodium chloride to be started at 100 mL per hour.

As you read this chapter, reflect on the challenges of fluid volume deficit in older adults and initiation of infusion therapy.

Intravenous (IV) therapy is the administration of fluids or medications via a needle or catheter (also called an cannula) directly into the bloodstream. Each state’s nurse practice act governs the practice of IV therapy in that state. Some states’ nurse practice acts now include IV therapy within the licensed practical nurse/licensed vocational nurse (LPN/LVN) role.

**LEARNING TIP**

National organizations provide guidelines, but you must follow your state Nurse Practice Act to decide which of those guidelines apply to you!

**INDICATIONS FOR INTRAVENOUS THERAPY**

A variety of substances can be administered via IV therapy, including fluids, electrolytes, nutrients, blood products, and medications. The solutions and/or medications can be given as a continuous or intermittent infusion (see “Types of Infusions”). Why do patients receive IV therapy? Many medications are faster acting and more effective when given via the IV route. The IV route also allows rapid delivery of medication in an emergency. Other medications can be administered continuously via IV to maintain a therapeutic blood level. Patients with anemia or blood loss can receive lifesaving IV blood transfusions. Patients can receive life-sustaining fluids, electrolytes, and nutrition via an IV when they are unable to eat or drink adequate amounts. Patients who are unable to eat for an extended period can have their nutritional needs met with peripheral parenteral nutrition (PPN) or total parenteral nutrition (TPN). The term parenteral refers to any medication route other than the digestive tract.

When a patient needs intermittent rather than continuous IV therapy, access to the bloodstream can be provided by a short peripheral vascular access device, sometimes called a saline lock, in which an IV cannula is inserted and covered with a sterile needleless cap or valve that seals after each use. (See “Intermittent Infusion” later in this chapter.) This provides access to the bloodstream for the prescribed intermittent or emergency medications, without the need for a continuous fluid infusion.

**TYPES OF INFUSIONS**

There are four primary administration modes for IV medications: (1) continuous, (2) intermittent, (3) direct injection, and (4) patient-controlled analgesia.

**Continuous Infusion**

A continuous infusion is a large-volume infusion of solution or medications (typically 250 to 1000 mL) administered over 2 to 24 hours. For a continuous infusion, the prescriber orders the infusion in milliliters to be delivered over a specific amount of time, such as 100 mL per hour or 1000 mL over 8 hours. The infusion is kept running at the prescribed rate until ordered to be discontinued.

**BE SAFE!**

**BE VIGILANT!** Always verify that orders are complete and understandable. If you have any questions, contact the RN, prescriber, or pharmacist.

Continuous infusions are used when a medication must be highly diluted, a constant plasma concentration of a drug must be maintained, or a large volume of fluids and electrolytes must be administered. Rate control is important in the delivery of continuous infusions and can be achieved by using an electronic infusion device (EID), mechanical controller, or roller clamp.

**Intermittent Infusion**

**Primary Intermittent Infusion**

These medications/solutions are delivered using a primary intermittent administration set that is connected and disconnected with each use.

**WORD • BUILDING •**

intravenous: intra—within + venous—vein
cannula: tube or sheath
parenteral: para—beside + enteral—intestines
Piggyback/Secondary Infusion

Some IV medications, such as antibiotics, need to be infused over a short period of time. For example, an antibiotic may be mixed with 50 mL of 5% dextrose or 0.9% sodium chloride solution and infused over 30 minutes. This is often done as an intermittent infusion. As with any IV therapy, the prescriber orders must specify route, drug, dose, and amount to be infused over a specified time. If the patient already has a primary continuous IV infusing, the antibiotic (secondary) infusion can be “piggybacked” into the primary IV line. This piggyback set is left attached to the primary administration set. For the piggyback medication to infuse, it must hang higher than the primary infusion (Fig. 7.1). Piggyback medications can be infused using a mechanical controller, roller clamp, or an electronic infusion device.

NEEDLELESS CONNECTORS. Needleless connectors are devices that allow connection to IV catheters (such as piggybacking into a primary IV line), administration sets, and syringes without using a needle. They are important for avoiding needle stick injuries in nurses. Needleless connector is the current recommended terminology by the INS (2011) and best describes all such devices. Other terms are used as well, such as injection cap, port, or injection valve.

The hub or extension set of a peripheral cannula that is covered with a needleless connector is sometimes called a saline lock (Fig. 7.2). Intermittent IV lines can be “capped off” with a needleless connector; this makes them available for intermittent or emergency access. In addition, because the needleless connector does not have to be removed to allow access, a sterile closed infusion system is maintained. Intermittent infusions are small volumes of fluid or medication administered over 15 minutes to 2 hours by IV push or infusion through the needleless connector.

The patency (unobstructed flow) of an intermittent cannula must be maintained by flushing at periodic intervals based on institution flushing policy and procedure. Always check for patency of an intermittent device before administering a

![FIGURE 7.1 Gravity drip setup with piggyback infusion.](image1)

![FIGURE 7.2 Peripheral IV with needleless connector attached to extension tubing. (Courtesy of Deb Richardson & Associates.)](image2)
medication. Do this by first scrubbing the hub; attach the syringe and draw back to check for backflow of blood; if blood is seen in the syringe, the needle is patent. Once patent, flush with normal saline (0.9% sodium chloride). To maintain patency of a cannula, flush the cannula after each use, or every 12 hours if not in use or according to institution policy. In addition to ensuring patency, flushing with saline also prevents the mixing of incompatible medications and solutions. The INS recommends the use of sodium chloride for maintaining peripheral intermittent venous access devices (CVADs). Remember that heparin is a medication and may be incompatible with other medications. Check your institution’s policy for specific guidelines.

Positive pressure must be maintained in the lumen of the cannula during the administration of the flush solution to prevent a backflow of blood into the cannula lumen, which could lead to occlusion of the lumen with a blood clot. The technique to maintain positive pressure is based on the type of needleless connector that is being used (Haday-Wong & Richardson, 2010):

- Negative fluid displacement—flush, clamp, then disconnect
- Positive fluid displacement—flush, disconnect, then clamp
- Neutral—no clamping technique required

BE SAFE!

BE VIGILANT! Always check for cannula patency and follow manufacturer’s guidelines for use before injecting any substance into the circulatory system. Forced flushing could cause a clot to dislodge from the cannula into the patient’s circulatory system.

If resistance is met while a cannula is being flushed, a clot may be occluding the cannula. Do not exert pressure on the syringe plunger in an attempt to restore patency because doing so may dislodge the clot into the vascular system or rupture the cannula.

BE SAFE!

BE VIGILANT! Always be aware of the type of needleless connector you are using, as well as manufacturer guidelines for its use.

Note: Some states require that registered nurses (RNs) administer medications given by the IV route; be sure to check your state’s nurse practice act regarding the role of the LVN/LPN in administering IV therapy.

Direct Injection/IV Push

An IV push, IVP, or direct injection medication is injected slowly via a syringe into an IV site or port. It is sometimes referred to as a bolus, which means “all at once.” IVP provides a rapid effect because it is delivered directly into the patient’s bloodstream. IV push drugs can be dangerous if they are given incorrectly, and a drug reference should always be checked to determine the safe amount of time over which the drug can be injected. IVP drugs are usually administered by RNs and are not within the scope of practice of the LPN/LVN in some states. However, you should be aware of the drugs being given so you can assist in observing the patient for desired or adverse effects.

Patient-Controlled Analgesia (PCA)

PCA is used to deliver analgesic or pain medications. An electronic infusion device (EID) or pump is used to deliver the analgesic drug. The EID is programmed to administer the prescribed amount to the patient when the patient presses a button. PCA administrations are usually done by RNs and may not be within the scope of practice for LPN/LVN. Verify with the state nurse practice act to determine whether PCA administration is within the LPN/LVN scope of practice. Again, you should be aware of the drugs being given so you can assist in observing the patient for desired or adverse effects.

Methods of Infusion

Gravity Drip

Gravity can be used to administer a solution into a vein (see Fig. 7.1). The solution is positioned about 3 feet above the infusion site. If it is positioned too high above the patient, the infusion may run too fast. If positioned too low, it may run too slowly. Flow is controlled with a roller, screw, or slide clamp. A mechanical flow device can be added to achieve accurate delivery of fluid with minimal deviation.

Calculating Administration Rates

When using a gravity set, you must calculate the infusion rate and/or the drops (i.e., gtt, L, guttae) required per minute to deliver fluid at the ordered rate. Commercial parenteral administration sets vary in the number of drops delivering 1 mL of fluid. Sets typically deliver 10, 15, 20, or 60 drops per milliliter of fluid. For example, to deliver 100 mL per hour using a set with 15-drop factor tubing, a flow rate of 17 drops per minute is needed. To administer the same amount using a set with 15-drop factor tubing, a flow rate of 25 drops per minute is needed. Check the label on the administration set to determine how many drops per milliliter (drop factor) are delivered by the set. Sets delivering 10, 15, or 20 drops per milliliter are called macrodrop sets and are used for fluids that need to be infused more quickly. Sets delivering 60 drops per milliliter are called microdrop or minidrop sets and are used for solutions that need to be infused more slowly.

To determine drops per minute for IV solution delivery, the nurse needs to know the amount of fluid to be given in a specified time interval and the drop factor of the administration set.
to be used. The formula for determining drops per minute is as follows:

$$\frac{\text{mL}}{\text{hr or hrs}} \times \frac{1 \text{ hr}}{60 \text{ min}} \times \frac{\text{gtt}}{1 \text{ mL}} = \text{gtt per minute}$$

**LEARNING TIP**

Always round to the nearest whole number when calculating drops per minute. You can’t deliver a fraction of a drop!

The formula for determining milliliters per hour is as follows:

$$\frac{\text{Total # of mL}}{\text{Total number of hr}} = \text{mL per hour}$$

**SAMPLE PROBLEMS.** Order: 125 mL of 5% dextrose and 0.45% sodium chloride per hour
Drop factor: 15 gtt/mL

\[
\frac{125 \text{ mL}}{1 \text{ hr}} \times \frac{1 \text{ hr}}{60 \text{ min}} \times \frac{15 \text{ gtt}}{1 \text{ mL}} = 31 \text{ gtt per minute}
\]

Order: Normal saline 1000 mL over 8 hours

\[
\frac{1000 \text{ mL}}{8 \text{ hours}} = 125 \text{ mL per hour}
\]

**LEARNING TIP**

If you are having trouble with IV and drug calculations, check out the Calculating Drug Doses tutorial on your Student CD!

**Factors Affecting Flow Rates of Gravity Infusions**

**CHANGE IN CANNULA POSITION.** A change in the position of the cannula’s tip can affect the infusion flow rate. If the bevel is against the wall of the vein, the flow rate will decrease; if it is away from the wall of the vein the flow rate can increase. Placement of a PIV in a joint area (wrist or elbow) can cause a kink in the cannula or change the tip position, which can cause a change in the flow rate. Careful cannula securement and a voiding areas of joint flexion will minimize this problem. Patients may need to be reminded to keep flexion to a minimum when an IV is placed near a joint.

**BE SAFE!**

**BE VIGILANT!** If the only useable vein is in an area of flexion, secure PIV appropriately; remind patients to keep flexion to a minimum; closely monitor PIV site and flow rate.

**HEIGHT OF THE SOLUTION.** Because infusions flow by gravity, a change in the height of the infusion bag or bottle or a change in the level of the bed can increase or decrease the flow rate. The flow rate increases as the distance between the solution and the patient increases. A patient may inadvertently alter the flow rate greatly simply by standing up. The ideal height for a solution is 3 feet above the level of the patient’s heart.

**PATENCY OF THE CANNULA.** A small clot or fibrin sheath can occlude the cannula lumen and decrease the flow rate or stop the flow completely. A fibrin sheath begins developing within the first twenty-four hours of the cannula insertion. Clot formation can result from irritation, vein wall injury from the insertion or tip position, increased venous pressure, or backup of blood into the cannula. Avoid use of a blood pressure cuff on the affected limb because of the resulting transient increase in venous pressure. A regular flush schedule helps maintain patency.

**MECHANICAL AND ELECTRONIC INFUSION DEVICES**

Flow-control devices, such as electronic infusion devices (EIDs) and mechanical controllers regulate the rate of infusion and are used in all healthcare settings (Fig. 7.3). Mechanical controllers measure the amount of solution delivered and depend on gravity to deliver the infusion. Electronic infusion devices, sometimes called pumps, use positive pressure to deliver the solution.

Pumps and controllers are used for infusing precise volumes and rates of solution. Institution policy often dictates use of controllers for infusion of potent medications, such as...
Dextrose solutions provide carbohydrates in a readily infused via a central line into a large vein. Concentrations exceeding 10% and above must be diluted, typically used for continuous peripheral infusions. Dextrose in water is available in many concentrations (2.5%, 5%, 10%) and is typically used for nutritional products such as parenteral nutrition and fat emulsions. Other types of filters (i.e., 1.2-micron) are used for nutritional infusions. Blood infusions generally use a standard 170-micron filter, which is built into the Y-administration set. Leukocyte-depleting filters are available for blood administration sets when concern for febrile reactions to leukocytes is anticipated (INS 2011; Roback, Combs, Grossman, & Hillyer, 2008). Other types of filters (i.e., 1.2-micron) are used for nutritional products such as parenteral nutrition and fat emulsions. Check institution policy and manufacturers’ guidelines for use of filters.

**TYPES OF FLUIDS**

There are three basic types of IV solutions: isotonic, hypotonic, and hypertonic (see Chapter 6). Fluids and electrolytes administered intravenously pass directly into the plasma space of the extracellular fluid compartment. They are then absorbed based on the characteristics of the fluid and the hydration status of the patient. The most commonly infused fluids are dextrose and sodium solutions. These are called crystalloid solutions.

**Crystalloid Solutions**

**Dextrose Solutions**

Dextrose in water is available in many concentrations (2.5%, 5%, 10%) and is typically used for continuous peripheral infusions. Concentrations exceeding 10% and above must be infused via a central line into a large vein.

Advantages of dextrose solutions are as follows:

- Dextrose solutions provide carbohydrates in a readily usable form and calories for energy, reducing breakdown of glycogen and catabolism of protein to help prevent negative nitrogen balance.
- They are nonelectrolyte and well metabolized by all tissues.
- High concentrations can be used for treating hypoglycemia or in combination with TPN because they supply a large number of calories.

Disadvantages of dextrose solutions are as follows:

- Vein irritation, damage, and thrombosis may result when hypertonic dextrose solutions are administered in a peripheral vein.

**Sodium Chloride Solutions**

Sodium chloride solutions are available in concentrations of 0.25%, 0.33%, 0.45%, 0.9% (normal saline), 3%, and 5%. Sodium chloride 0.9% and 0.45% solutions are used most commonly.

- Advantages of sodium chloride solutions are as follows:
  - Sodium chloride solutions are used for fluid replacement; treatment of shock, hyponatremia, and metabolic acidosis; as a primer for blood transfusions and during resuscitation after trauma. According to the American Association of Blood Banks, blood component administration sets can be primed only with 0.9% sodium chloride solution (Roback et al, 2008).
  - Combination dextrose and sodium chloride solutions, such as 5% dextrose with 0.45% sodium chloride (often referred to as “D5 and a half”), are commonly used for hydration and to check for kidney function before administration of potassium replacement therapy.

Disadvantages of sodium chloride solutions are as follows:

- They can cause circulatory overload if the prescribed rate is not monitored.
- If the patient is unable to excrete excess sodium (due to kidney disease or hormonal imbalance, for example) hypernatremia can result.

**Balanced Electrolyte Solutions**

Electrolyte solutions are used to replace lost fluids and electrolytes. A variety of balanced electrolyte solutions are available commercially. Maintenance electrolyte solutions, such as lactated Ringer’s solution, approximate normal body electrolyte needs. Balanced solutions often contain lactate or acetate (yielding bicarbonate), which helps combat acidosis and provide a truly balanced solution. Potassium is an electrolyte that is commonly added to balanced solutions to replace potassium deficits. The patient must be monitored for signs and symptoms related to potassium imbalance (see Chapter 6).

**BE SAFE!**

**BE VIGILANT!** Be sure to review institution guidelines for potassium administration before administration of any potassium-containing solution. An inappropriate rate or amount can cause a life-threatening cardiac dysrhythmia.

**Osmolarity of IV Solutions**

The osmolarity of an IV solution refers to its osmotic activity. As noted previously, IV fluids may be classified as isotonic, hypotonic, or hypertonic. (See Chapter 6 to review these concepts.) Isotonic fluids have the same concentration of solutes to water as body fluids. Hypertonic solutions have more solutes (are more concentrated) than body fluids. Hypotonic solutions have fewer solutes (are less concentrated) than body fluids.
fluids. Water moves from areas of lesser concentration to areas of greater concentration. Therefore, hypotonic solutions send water into areas of greater concentration (cells), and hypertonic solutions pull water from the more highly concentrated cells.

Isotonic Solutions
Normal saline (0.9% sodium chloride) solution is an isotonic solution that has the same tonicity as body fluid. When administered to patients requiring water, it neither enters cells nor pulls water from cells; it therefore expands the extracellular fluid volume. A solution of 5% dextrose in water (D5W) is also isotonic when infused, but the dextrose is quickly metabolized, making the solution hypotonic. Lactated Ringer’s and 5% albumin are other examples of isotonic solutions.

Hypotonic Solutions
Hypotonic fluids are used when fluid is needed to enter the cells, as in the patient with cellular dehydration. They are also used as fluid maintenance therapy. Examples of hypotonic solutions are Dextrose 2.5% water and 0.33% or 0.45% sodium chloride solution.

Hypertonic Solutions
Examples of hypertonic solutions include 5% dextrose in 0.9% sodium chloride, 3% sodium chloride, calcium chloride 10%, and 5% dextrose in lactated Ringer’s solution. Hypertonic solutions are used to expand the plasma volume, for example, in a hypovolemic patient. They are also used to replace electrolytes.

**BE SAFE!**
Monitor the patient receiving a hypertonic solution for circulatory overload.

**INTRAVENOUS ACCESS**
IV therapy can be administered into the systemic circulation via the peripheral or central veins. Peripheral veins lie beneath the epidermis, dermis, and subcutaneous tissue of the skin. They usually provide easy access to the venous system. Central veins are deeper and located closer to the heart. Special catheters with a tip that ends in a large vessel (i.e., superior vena cava) near the heart are CVADs. This chapter primarily focuses on short peripheral catheters. The definitions of the various types of CVADs are discussed briefly at the end of the chapter.

**INITIATING PERIPHERAL INTRAVENOUS THERAPY**

Starting a Peripheral (Short-Cannula) Infusion (Phillips, 2010)

Precannulation (Steps 1–5)

**STEP 1: CHECK AUTHORIZED PRESCRIBER’S ORDER.** A physician or authorized prescriber’s order is needed to start IV therapy. The order should include patient identification, solution and type, dosage, volume, rate, route, frequency, and anything requiring significant attention.

**STEP 2: PERFORM HAND HYGIENE.** Hand hygiene has been shown to significantly decrease the risk of contamination. Before beginning the procedure, wash your hands for a minimum of 15 to 20 seconds with antimicrobial soap and running water or alcohol-based hand rub.

**STEP 3: GATHER, INSPECT, AND PREPARE EQUIPMENT.**
- Clean gloves
- Skin prepping solution (i.e., 70% isopropyl alcohol, chlorhexidine gluconate, or chlorhexidine gluconate/ alcohol combination)
- Sterile 2” × 2” gauze pads
- Towel or drape to place under selected IV site
- Alcohol prep pads
- Securement device
- Prefilled saline syringe (10 mL) or normal saline vial with 10-mL syringe and 20-gauge needle
- Sterile extension set to attach to cannula hub
- Dressing material
- Disposable nonlatex, single-use tourniquet
- PIV cannulas (over-the-needle sizes 18, 20, 22, and 24 are the most common)
- Appropriate administration set, if indicated
- IV solution, if indicated (Inspect and gently squeeze soft plastic bags for puncture holes or breaks; check expiration date; inspect solution for visible contamination or particles; ensure that outer wrap is dry.)
- Needleless connector
- IV pole, if needed
- Infusion pump, if needed
Some institutions have IV start kits that contain supplies needed.

**STEP 4: IDENTIFY, ASSESS, AND PREPARE THE PATIENT.**

**Patient Identification.** The 2014 National Patient Safety Goals established by the Joint Commission (© The Joint Commission, 2013. Reprinted with permission) specify that two patient identifiers should be used when administering medications, blood, or blood components. The patient’s room number or physical location should not be used as an identifier.

**Patient Assessment.** Several factors must be considered before venipuncture: type of solution to be infused, condition of vein, duration of therapy, cannula size needed, patient age, patient activity, presence of disease or previous surgery, presence of a dialysis shunt or graft, medications being taken by the patient (such as anticoagulants), allergies, and patient preference for site. In addition, be sure to assess specific needs related to the patient’s culture (see “Cultural Considerations”).

**Psychological Preparation.** Provide privacy, explain the procedure and the reason why the IV is needed, evaluate the patient’s knowledge of the procedure before assessing the patient’s arms for suitable venipuncture sites. Ask if the patient has had experience with infusions before and if he or she experienced any difficulties with venipuncture or the infusion. Make sure the patient is comfortable. Distraction techniques or music therapy may assist in reducing anxiety.

**STEP 5: SELECT SITE AND DILATE VEIN.**

**Site Selection.** Proper vein/site selection is crucial to the success of the procedure and the infusion treatment (INS 2011; Box 7-1). Avoid use of an arm on the side where the patient has had a mastectomy, has a dialysis access site, or is scheduled for a surgical procedure. The patient’s condition and diagnosis; age; vein condition, size, and location; type/duration of therapy; and experience of the inserter should be considered before starting IV therapy (Box 7-2). The PIV cannula selected should be the least invasive with the smallest gauge and length needed to accommodate the ordered therapy (INS, 2011).

The first cannula should be started in the most distal site that supports therapy. This allows each successive venipuncture to be made proximal to the site of the previous one, which eliminates the passage of irritating fluids through a previously injured vein and minimizes leakage through old puncture sites. Hand veins can be used successfully for most hydrating solutions, but they are best avoided when irritating solutions of potassium or antibiotics are anticipated.

Vein size must also be considered. Small veins do not tolerate large volumes of fluid, high infusion rates, or irritating solutions.

---

**Box 7-1 Considerations for Vein Selection**

- Age of patient
- Availability of sites
- Size of cannula to be used
- Purpose of infusion therapy
- Osmolarity and pH of solution to be infused
- Volume, rate, and length of infusion
- Degree of mobility desired

**Box 7-2 General Considerations for Initiating IV Therapy**

2. When multiple sticks are anticipated, make the first venipuncture distally and work proximally with subsequent punctures. Make no more than two attempts at venipuncture before getting help.
3. Use only one cannula per cannulation attempt.
4. If therapy will be prescribed for longer than 6 days, a peripherally inserted central catheter (PICC) or other type of CVAD should be considered.
5. Avoid using venipunctures in affected arms of patients with radical mastectomy or a dialysis access site.
6. If possible, avoid taking a blood pressure on the arm receiving an infusion because the cuff interferes with blood flow and forces blood back into the cannula. This may cause a clot or cause the vein or cannula to rupture.
7. Select the smallest cannula in gauge and length that supports prescribed therapy. All cannulas should be radiopaque.
8. All peripheral cannulas should be stabilized with a stabilization device to preserve the integrity of the access device and prevent migration.

---

**Cultural Considerations**

Among the Vietnamese, the head is considered sacred. Thus, the practice of starting IV lines in the scalp may cause a Vietnamese patient significant anxiety. Consider other sites first. If the patient must have an IV line in the scalp, carefully explain why it is needed.
Large peripheral veins should be used for these purposes. Figure 7.4 shows peripheral veins that can be used for IV therapy.

**BE SAFE!**

**BE VIGILANT!** Pay attention to the vein when choosing a cannula size. A smaller gauge cannula takes up less space within the vein, allows for better blood flow around the cannula, and decreases trauma to the vein wall.

**Vein Dilation.** If veins are constricted, venipuncture is more difficult. Fever, anxiety, and cold temperatures can cause veins to constrict. Smoking before the insertion of an IV line also causes veins to constrict.

---

A tourniquet helps to dilate and stabilize the vein, easing venipuncture and threading of the cannula. Place the tourniquet 6 to 8 inches above the insertion site. If the tourniquet is too close to the insertion site, it can create too much pressure and cause a **hematoma**, which is a localized collection of blood in the subcutaneous tissue. The tourniquet should be tight enough to impede venous flow while maintaining arterial flow. A tourniquet should be at least 1 inch wide and should not be left on for more than 3 minutes to prevent impaired blood flow to the extremity. Use a non-latex, single-use tourniquet. Tourniquets should be applied loosely or not used at all in patients with fragile veins or who bruise easily.

---

**NURSING CARE TIP**

Many patients know from experience whether their veins are difficult to access. Asking a patient to indicate his or her “best vein” may decrease the number of attempts before successful IV cannulation. When selecting a hand vein, avoid the patient’s dominant hand, if at all possible, to avert accidental removal of the IV by the patient.

Occasionally, additional techniques are needed to distend a vein. Placing the arm in a dependent position or placing a warm towel over the site for several minutes before applying the tourniquet helps to dilate a vein. The whole extremity must be warmed to improve blood flow to the area. Opening and closing the fist pumps blood to the extremity and increases blood flow to help dilate the vein. Lightly stroking downward on the vein may also help. A blood pressure cuff inflated to 30 mm Hg is another appropriate method for vein dilation, especially with fragile veins in older adults. Box 7-3 lists additional tips for difficult-to-find veins.

---

**BE SAFE!**

Use a tourniquet only once to avoid cross-contamination between patients. Tourniquets may also be sources of latex exposure; use a non-latex tourniquet or blood pressure cuff technique for patients whenever appropriate.

---

**Cannulation (Steps 6–10)**

**STEP 6: SELECT CANNULA.** Needles have been largely replaced with flexible plastic catheters (cannulas) that are inserted over a needle (Fig. 7.5). The needle (or stylet) is removed or retracted after the cannula is in place.

---

* **WORD • BUILDING •**

**hematoma:** hemat—blood + oma—tumor
**Box 7-3 Techniques for Patients With Difficult Venous Access**

**Impaired skin integrity related to lesions, burns, or disease process**
- Use light directed toward the side of the patient’s extremity (tangential lighting) to illuminate blue veins. (This technique can also be used on dark-skinned people.)
- Do not flatten veins or cause damage to skin.
- Use a vein illumination device, which uses technology that shines a special light to identify veins beneath the surface of the skin.

**Hard sclerosed vessels related to disease process, personal misuse, frequent drug therapy**
- Assess for collateral circulation.
- Use multiple tourniquet technique to increase oncotic pressure inside the tissue, forcing small vessels of periphery to be visualized:
  - Place one tourniquet high on arm for 2 minutes and leave in place; stroke downward toward hand.
  - After 2 minutes, place a second tourniquet at midarm just below the antecubital fossa; leave along with first tourniquet for 2 minutes.
  - This should bring peripheral veins into view; if needed, place a third tourniquet at wrist.
  - Do not leave on for more than 6 minutes total.
  - Use a vein illumination device.

**Obesity or edema**
- Use a 2-inch cannula.
- Use multiple tourniquet technique.
- Press down on tissue to displace edema to side to visualize veins.

**BE SAFE!**

PIV technology has been designed to prevent or decrease the risk of needlestick injury and blood exposure. Safety (passive or active) PIVs provide protection against needlestick injury (see Fig. 7.5). Other safety PIV devices have been designed not only to prevent needlestick injury but to control or prevent blood leakage, spill, or splatter at the time of insertion and/or maintenance.

**FIGURE 7.5**
(A) Insyte Autoguard. (B) BD Nexiva Closed IV Catheter System. (C) BD Insyte Autoguard BC Shielded IV Catheter. (D) BD SAF-T-EZ set. (Courtesy and © Becton, Dickinson and Company. Reprinted with permission.)
For patient comfort, choose the smallest gauge cannula that will work for the intended purpose. Use smaller gauge cannulas (22–24 gauges) for fluids and slow infusion rates. Use larger cannulas (18–20 gauges) for rapid fluid administration and viscous solutions such as blood. Also consider vein size when choosing a cannula gauge. Refer to institution policy and equipment stock for specific recommendations. For adult and pediatric patients, the INS (2011) recommends that short peripheral cannulas be removed only when clinically indicated and immediately upon suspected contamination. INS also instructs clinicians to replace or remove any PIV cannula placed in an emergency situation within 48 hours of the insertion or as soon as possible (INS, 2011).

STEP 7: PUT ON GLOVES. The INS (2011) and the Occupational Safety and Health Administration (2009) recommend following standard precautions whenever exposure to blood or body fluids is likely: wear clean latex or vinyl gloves to provide basic minimal protection from blood and body fluids. Remove gloves after contact with a patient, using proper technique to prevent hand and environmental contamination; wash hands after glove removal.

STEP 8: PREPARE THE SITE. Some agency policies allow the use of a local anesthetic agent before insertion of a peripheral IV cannula to minimize pain during the insertion. Be sure to check your agency’s policy. Local anesthetic agents include lidocaine, iontophoresis low-frequency ultrasonification, pressure-accelerated lidocaine, and topical transdermal agents.

Clean the insertion site with an antiseptic/antimicrobial solution before cannula placement. If the patient’s skin is visibly dirty, wash it with soap and water before applying the solution. If the patient has excess hair, it can be clipped with scissors or disposable-head surgical clippers. Avoid using a razor, which can cause skin irritation. Acceptable solutions include, but are not limited to, 70% alcohol or alcohol/chlorhexidine gluconate combination (A & CHG). CHG is the preferred prep solution of choice based on scientific evidence (O’Grady et al. 2011, INS, 2011). Avoid using alcohol after an antimicrobial preparation because alcohol negates the antimicrobial action of the skin prep agent.

Follow manufacturers’ instructions for your chosen solution. Typically alcohol and povidone-iodine (PI) are applied in a circular motion, starting at the intended site and working outward to clean an area 2 to 3 inches in diameter. A & CHG combination solution is applied using a back-and-forth technique. Regardless of antiseptic solution used, it should be applied with friction for at least 30 seconds. Blotting of excess solution at the insertion site is not recommended. Let the solution air dry completely before inserting the PIV cannula.

STEP 9: INSERT THE CANNULA. Make sure you have good lighting to visualize the vein. Venipuncture can be performed using a direct (one-step) or indirect (two-step) approach. For the direct approach, the cannula enters the skin directly above the vein. Small, fragile veins can be bruised more easily with the direct method. In the indirect approach, the cannula is inserted through the skin, the vein is located and the cannula is then inserted into the vein. This method is useful when cannulating small, fragile veins as bruising is less likely to occur.

Hold the cannula with the bevel (slanted opening) of the needle facing up. With the tourniquet in place, pull down on the skin to help stabilize the vein and then enter the skin/vein at a 10- to 30-degree angle using either the direct or indirect approach (Fig. 7.6).

NURSING CARE TIP

Use traction (a downward pulling motion that makes the skin taut below the puncture site) to stabilize the skin and prevent the vein from rolling during venipuncture (Fig. 7.7).

Once the skin is punctured, lower the needle angle and locate and puncture the vein. Depending on the type of device used, a small flash of blood may be seen in the tubing or at

BE SAFE!

BE VIGILANT!

1. It is important to allow the skin prep to dry completely. This allows the prep to do its job, which is to kill off as much skin bacteria as possible. It also decreases the risk of tracking the solution into the vein during insertion, which can lead to phlebitis.

2. Do not repalpate the site after prepping it. If you need to repalpate after cleaning, you must change to sterile gloves to perform this step (INS, 2011).

FIGURE 7.6 Insert the needle of choice bevel up at a 10- to 30-degree angle, depending on the vein location and catheter.
the hub of the cannula when the needle is in the vein. With the angle of the needle lowered so that it is parallel with the skin, thread it into the lumen of the vein. If a cannula-over-needle device is used, advance the cannula device 1/16th of an inch and then advance the cannula gently into the vein for its remaining length. Once the cannula is threaded into the vein, engage the safety mechanism according to device instructions to withdraw the needle out of the plastic cannula.

Once the cannula is in place, release the tourniquet and connect the preflushed extension set and needleless connector to the cannula hub. Blood may ooze from the hub at this time, so be sure to follow precautions against exposure. Clean the needleless connector and check for patency by aspirating for a blood return and flushing the cannula with 0.9% sodium chloride solution. A smooth, easy flush and good blood return along with no signs of infiltration or pain indicate that the cannula is patent and that the prescribed solution can be administered. If an IV solution is to be infused, clean the needleless connector, connect the IV tubing and initiate the infusion. Box 7-4 lists troubleshooting tips for peripheral cannula insertions.

**STEP 10: STABILIZE THE CANNULA AND DRESS THE SITE.** The purpose of cannula stabilization is to (1) preserve the integrity of the access device, (2) prevent cannula movement, and (3) decrease potential complications such as phlebitis, infiltration, or loss of the device. The stabilization technique should not interfere with visualization and evaluation of the insertion site or affect circulation. Several methods may be used to stabilize the cannula hub, including transparent dressings, tape, and specialized securement devices.

A transparent semipermeable membrane (TSM) dressing allows the venipuncture site to be monitored for redness or swelling and provides an occlusive dressing for the site. Other choices include sterile gauze or hydrocolloidal dressings. The dressing choice should be based on the patient’s needs. Band-Aids® are not acceptable dressings over cannulas.

Arm boards, finger splints, or limb splints can be used to stabilize cannulas that are placed near joints. These devices should only be used to assist in the delivery of the infusion and to decrease the risk of complications. However, if a confused patient places the IV site in danger the extremity can be immobilized as a last resort; this requires a HCP’s order. If a joint stabilization device is used, make sure the insertion site and vein path can be seen and that placement of the device does not affect circulation or cause skin or nerve damage.

**Box 7-4 Troubleshooting Tips for Peripheral IV Therapy**

Common reasons for failure of venipuncture include:

- Failure to release the tourniquet promptly when the vein has been successfully cannulated
- Use of a “stop and start” technique by beginners who lack confidence—a tentative approach that can injure the vein, causing a hematoma
- Inadequate vein stabilization, as can occur when traction is not used to hold the vein, causing the stylet to push the vein aside
- Failure to recognize that the cannula has gone through the opposite vein wall
- Stopping too soon after insertion of only the stylet so that the cannula does not enter the lumen of the vein (causing blood return to disappear when the stylet is removed because the cannula is not in the lumen of the vein)
- Attempting to insert the cannula too close to a bifurcation
- Inserting the cannula too deep, below the vein
- Failure to penetrate the vein wall because of improper insertion angle (too steep or not steep enough), causing the cannula to ride on top of or below the vein
- Poor venous access

**NURSING CARE TIP**

Dressing changes for PIV catheters are only done if the dressing is dirty or no longer intact. CVAD dressings should be changed every 2 days for a gauze dressing and every 5 to 7 days for a transparent semipermeable membrane dressing—sooner if it is dirty or no longer intact or if bleeding, drainage, or infection is noted (INS, 2011).

**Post-Cannulation (Steps 11–15)**

**STEP 11: LABEL THE SITE.** The IV setup should be labeled in three areas: the insertion site, the tubing, and the solution container. Once the venipuncture procedure is completed, label the insertion site dressing with the date, time, cannula type/size and length, and your initials; label tubing and solution (if applicable) with date, time, and initials.
STEP 12: DISPOSE OF EQUIPMENT AND PERFORM HAND HYGIENE. Equipment disposal should follow CDC guidelines and INS standards of practice for biohazards. All needles, cannulas, and blood-contaminated equipment should be disposed of according to institution policy in tamper-proof, nonpermeable, biohazard waste containers. Remove gloves and wash your hands.

STEP 13: EDUCATE THE PATIENT. Patients have the right to receive information on all aspects of their care in a manner they can understand. They also have the right to accept or refuse treatment. The following information should be included in education and documentation:

• Reason IV is needed and for how long.
• Limitations on mobility that result from the IV placement.
• Medications ordered and why; side effects to report.
• Meaning of alarms if an electronic infusion device is used.
• How to call for assistance if the venipuncture site becomes tender or sore or if redness or swelling develops.

STEP 14: CALCULATE DRIP RATE. All IV infusions should be monitored frequently for accurate flow rates and complications associated with infusion therapy. See the section on calculating drip rates earlier in this chapter.

STEP 15: DOCUMENT. After implementation of infusion therapy, the procedure must be documented in the medical record. Document your actions and the patient’s response according to institution policy. All IV solutions are also documented on the medication administration record. Include the following:

• Date and time of insertion
• Manufacturer’s brand name and style of device
• Gauge and length of the device
• Location of the accessed vein
• Presence of good blood return and patency of device
• Solution infusing and rate of flow
• Application of stabilization technique and dressing applied
• Method of infusion (gravity or pump)
• Flush solution-heparin or saline and amount used, if applicable
• Number of attempts needed for a successful IV start
• Patient’s response and specific comments related to the procedure
• Patient education related to the procedure
• Signature

CRITICAL THINKING

Mrs. Green

Mrs. Green is admitted with a diagnosis of symptomatic anemia and has an atrioventricular (AV) dialysis shunt in her left arm. An IV line is ordered for administration of 2 units of packed red blood cells. What must be taken into consideration when assessing Mrs. Green for an appropriate venipuncture site?

Suggested answers are at the end of the chapter.

NURSING PROCESS FOR THE PATIENT RECEIVING IV THERAPY

IV therapy is a medical intervention, and the nurse is responsible for appropriate assessment, monitoring, documentation, and reporting related to the therapeutic goals.

Data Collection

Some institutions require assessment as often as every hour. An INS Position Paper (Gorski et al, 2012) provides some guidance on frequency of site assessment including the following recommendations:

• At least every 4 hours for patients not getting an irritant or vesicant and who are alert and oriented
• Every 2 hours for critically ill patients and adult patients with cognitive sensory deficits; receiving sedative medications or unable to notify the nurse of any problems; or if IV is placed in a joint area or external jugular vein
• Every hour for pediatric or neonatal patients

Assessment should be systematic and thorough and include physiological and psychosocial data, critical laboratory values, allergies and environmental issues, and presence of adverse reactions or complications related to infusion therapy.

Older adults are at increased risk for complications, making careful assessment essential (see “Gerontological Issues”).

Gerontological Issues

Care of the Older Adult Receiving Intravenous Therapy

When an older patient is receiving IV fluids, the nurse must regularly assess the patient for potential fluid volume excess. Symptoms of fluid volume excess include the following:

• Elevated blood pressure
• Increasing weight
• Full bounding pulse
• Shallow, rapid respirations
• Jugular venous distention
• Increased urine output
• Development of moist crackles in the lungs.

If these signs are present:

• Immediately notify the RN or turn down the IV to a minimum drip rate (1 mL per minute); do not discontinue the IV because the HCP may want to order IV diuretics.
• Position the patient to maximize lung expansion.
• Check peripheral oxygen saturation with an oximeter.
• Apply oxygen by mask or nasal cannula if indicated and per institution guidelines.
• Closely monitor patient’s vital signs, level of consciousness, and oxygen saturation along with fluid output.
• Assist the HCP or RN with IV push administration of diuretic medication such as furosemide if ordered.
Physical assessments such as daily weights and measurement of intake and output (I&O) help determine whether the patient is retaining too much fluid. Skin turgor, mucous membrane moisture, vital signs, and level of consciousness also indicate hydration status. New onset of fine crackles in the lungs can indicate fluid retention. Table 7.1 lists other symptoms of complications, along with prevention and treatment strategies.

### Table 7.1 Complications of Peripheral IV Therapy

<tr>
<td><strong>Local Complications of IV Therapy</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Hematoma | • Ecchymoses  
• Swelling  
• Inability to advance cannula  
• Resistance during flushing | Use indirect method of venipuncture.  
Choose smallest cannula appropriate.  
Apply tourniquet just before venipuncture. | Remove cannula.  
Apply pressure with 2” × 2” gauze.  
Elevate extremity. |
| Thrombosis | • Slowed or stopped infusion  
• Fever/malaise  
• Inability to flush or aspirate cannula | Use an electronic infusion device (EID).  
Choose microdrop sets with gravity flow if rate is less than 50 mL/hr.  
Avoid use of flexion areas for insertion site. | Discontinue cannula.  
Apply cold compress to site.  
Assess for circulatory impairment.  
Insert new cannula at another site. |
| Phlebitis | • Redness/warmth at site  
• Local swelling  
• Pain  
• Palpable cord  
• Sluggish infusion rate | Use larger veins for hypertonic solutions.  
Choose smallest cannula appropriate.  
Use good hand hygiene.  
Add buffer to irritating solutions.  
Change solutions and containers every 24 hours.  
Assess PIV site per institution policy.  
Remove cannula when clinically indicated. | Discontinue cannula.  
Apply cold compress initially; then warm.  
Consult RN or provider if severe. |
| Infiltration or Extravasation | • Coolness of skin at site  
• Taut skin  
• Dependent edema  
• Absent backflow of blood  
• Sluggish infusion rate  
• Pain or burning (depending on solution used) | Place cannula in appropriate site.  
Avoid antecubital fossa.  
Stabilize cannula carefully.  
Monitor PIV site per policy.  
Instruct patient to notify nurse immediately if any pain, burning or swelling occurs. | Discontinue cannula.  
Apply cool compress if appropriate.  
Elevate extremity slightly.  
Notify RN/provider.  
Follow agency infiltration/extravasation guidelines.  
Have antidote available (if medication extravasates). |
| Local Infection | • Redness and swelling at site  
• Possible exudate  
• Elevated white blood cell (WBC) count  
• Elevated T lymphocytes | Inspect all solutions.  
Use sterile technique during venipuncture and site maintenance. | Discontinue cannula.  
Culture site and cannula.  
Apply sterile dressing over site.  
Notify RN/HCP.  
Administer antibiotics if ordered. |

CRITICAL THINKING

Mr. Rick

Mr. Rick’s IV has blood back ed up in the tubing. When you open the clamp to increase the flow, nothing happens. What should you do?

Suggested answer is at the end of the chapter.

Inspect the insertion site for redness or swelling, evaluate the integrity of the dressing, and document your findings. Inspect the tubing to ensure tight connections and the absence of kinks or defects. Inspect the solution container and compare it with the HCP’s order for type, amount, and rate. Report abnormal findings to the RN or HCP.

Nursing Diagnoses, Planning, and Implementation

Priority nursing diagnoses for IV-related issues may include the following.

Fear related to insertion of IV cannula

**EXPECTED OUTCOME:** The patient will have minimal fear as evidenced by cooperation with the procedure and verbalizing minimal fear.

- Explain the IV therapy (rationale for therapy, insertion procedure, care of the IV, and importance of reporting pain, swelling, or pump alarm) to the patient. Lack of knowledge is associated with fear.
- Use techniques to minimize discomfort. Pain may increase fear.

Impaired Physical Mobility related to placement and maintenance of IV cannula

**EXPECTED OUTCOME:** The patient will maintain mobility as evidenced by full range of motion and avoidance of complications related to immobility.

- Avoid insertion site close to joints if at all possible. Joint areas are mobile, making it difficult to maintain an intact site.
- If you must use a mobile site, such as the antecubital fossa or wrist area, immobilize the joint with arm board or other immobilizer to reduce cannula movement. (Remember to get an order for this.)
- If site must be wrapped to protect from movement, be sure to leave insertion site visible or remove wrapping to view site according to agency policy. The site must still be visualized for complications even if it is covered.
- Assist patient with activities of daily living (ADLs). The patient may have difficulty with ADLs if movement is limited.

Risk for Infection related to broken skin or traumatized tissue

**EXPECTED OUTCOME:** The patient will be free from infection as evidenced by no redness, swelling, or purulence at IV insertion site, no fever, and normal white cell count.

- Watch for signs of infection so the IV can be removed and/or site rotated and infection treated quickly if it occurs.

- Use good hand hygiene and strict aseptic techniques during cannula insertion and maintenance care to prevent introduction of pathogens.
- Change tubing, and solutions regularly according to agency policy to prevent growth of microorganisms.
- Change or remove cannula when clinically indicated to reduce prolonged risk.

Evaluation

The RN is responsible for evaluation of outcomes and thus monitors the patient for evidence that the goals of therapy are being met and that complications are avoided. The LPN/LVN collects data that contribute to the evaluation. For example, if antibiotic therapy is administered, monitor the patient’s temperature and other signs that the infection is resolving. If IV therapy is ordered to correct dehydration, monitor daily weights, skin turgor, vital signs, and other appropriate signs of improved fluid balance. Document all findings and report them to the RN.

COMPICATIONS OF IV THERAPY

Complications of infusion therapy fall into two categories: local and systemic. Any complication or unusual incident should be reported to the RN or HCP, and a quality improvement report should be prepared according to institution policy.

The most common peripheral local complications are hematoma, phlebitis, infiltration/extravasation, and nerve injury. Systemic complications can be serious and include circulatory overload, septicemia, venous air embolism, and speed shock (a sudden reaction due to medication that is delivered too quickly). The nurse delivering infusion therapy must be knowledgeable in preventing, recognizing, and treating all complications of IV therapy (INS, 2011).

See Table 7.1 for complications, prevention, and related care.

CRITICAL THINKING

Mrs. Gonzalez

Mrs. Gonzalez is receiving 5% dextrose in water at 83 mL per hour. One hour after the infusion starts, she reports pain at the site. The site is cool to the touch and swollen, and the infusion rate is sluggish.

1. What might be happening?
2. What additional data should you collect?
3. What action should you take?
4. How should you document your findings?
5. What other team members could be consulted to help in this situation?

Suggested answers are at the end of the chapter.
The role of the LPN/LVN in CVA care in most states is limited to assisting the RN with assessments. Therefore, it is important for you to be familiar with the different CVADs so you can recognize and report problems.

Central venous catheter tips terminate in the superior vena cava near the heart (Fig. 7.8). They are used when peripheral sites are inadequate. CVADs can be used to deliver all types of solutions, medications, blood, or blood products when continuous infusion is required. They are also beneficial when irritant or vesicant medication must be given into a large vein. CVADs include tunneled and nontunneled catheters, peripherally inserted central catheters (PICCs), and implanted ports. These devices can have one, two, or three lumens in the catheter or one or more port chambers. Each lumen of a multilumen device exits the site in a separate line, called a tail. Multilumen devices allow simultaneous administration of solutions while preventing mixing of incompatible solutions.

Be careful not to confuse a central catheter with a dialysis catheter. Dialysis catheters should be used only for dialysis and not for IV therapy and should be accessed only by HCPs or specially trained dialysis nurses. If you are not sure what type of catheter your patient has, be sure to ask the RN or provider.

**Nontunneled Central Catheter**
A nontunneled CVAD is inserted by a physician or licensed independent practitioner into the jugular, subclavian, or femoral vein. After insertion, correct placement is determined by x-ray before the catheter is used. These short-term CVADs may remain in place up to several weeks, but placement time is typically about 7 days. A nontunneled CVAD can be inserted at the bedside or in an outpatient setting and are cost effective for short-term CAV. Nontunneled CVADs can be used for many purposes and can be easily exchanged. However, there are disadvantages, such as ongoing maintenance care and body image issues.

**Tunneled Catheters**
Tunneled catheters are used when venous access is needed for months to years. These catheters are typically composed of polymeric silicone with a Dacron polyester cuff that not only anchors the catheter in place subcutaneously but also provides a barrier to prevent bacteria from migrating to the tip of the catheter. The catheter tip is commonly placed in the superior vena cava (see Fig. 7.8C).

Advantages of a tunneled catheter are that a break or tear in a catheter is easy to repair, and they can be used for many purposes. Disadvantages include such concerns as weekly site care, cost of maintenance supplies, and the effect on the patient’s body image.
Peripherally Inserted Central Catheter

A PICC is a long catheter that is inserted in the arm and terminates in the central vasculature (see Fig. 7.8B). A PICC can be tunneled or nontunneled. This device is used when therapy will last more than 2 weeks or the medication is too caustic for peripheral administration. Specially trained RNs can insert PICC lines. They can be left in place for long periods, minimizing the trauma of frequent IV insertions. Consult with the HCP for a PICC order if long-term therapy is anticipated.

It is important to follow the manufacturer’s recommended guidelines for flushing the catheter and to be aware of your institution’s PICC policy. A trained RN removes the PICC catheter when therapy is terminated. An LPN/LVN may assist the RN with this procedure if the state nursing practice act permits.

Ports

A port is a reservoir that is surgically implanted into a pocket created under the skin, usually in the upper chest; a catheter is attached to the reservoir and is tunneled under the skin into a central vein such as the superior vena cava. An advantage of a port is that when not in use, a dressing is not required, and it can be flushed and left unused for long periods. When the port not in use, the patient can swim and shower without risk of contaminating the site.

Ports come in a variety of sizes and styles and are no longer being placed in many areas of the body. Ports are suitable for long-term therapy and can be used to administer all types of medications, including chemotherapeutic agents and antibiotics that are toxic to tissues. In addition, ports can be used for radiology imaging and procedures. Ports are usually accessed only by specially trained RNs and require the use of noncoring needles that are specifically designed for port access and infusions.

BE SAFE!

BE VIGILANT! Implement evidence-based practices to prevent central line–associated bloodstream infections. This requirement covers short- and long-term central venous catheters and PICC lines (2013 National Patient Safety Goals, www.jointcommission.org). Vascular catheter–related infections are considered “never events” because they can be prevented and should never occur. Hospitals will not be paid by Medicare for such infections acquired during hospitalization.

OTHER THERAPIES

Nutritional Support

Total parenteral nutrition (TPN) is complete IV nutrition that is administered to patients who cannot take adequate nutrients via the enteral route (by mouth or tube feeding). TPN may be used to promote nutrition for wound healing, to help a patient achieve optimal weight before surgery, or to avoid malnutrition from chronic disease or after surgery. Patients with ulcerative colitis, trauma, or cancer cachexia (wasting syndrome) are candidates for TPN. Every effort should be made to return a patient on TPN to oral or tube feedings as soon as possible.

TPN provides and maintains the essential nutrients required by the body. Solutions contain carbohydrates, amino acids, lipid emulsions, electrolytes, trace elements, and vitamins in varied amounts according to the patient’s needs. Parenteral nutrition requires filtration and an electronic infusion device for administration. In the home setting, an ambulatory infusion device is used to allow the patient more mobility.

Initial assessment includes the patient’s height, daily weight, nutritional status, and current laboratory values. Because of the high glucose concentration of TPN, the patient is at risk for infection and blood glucose disturbances. Insulin therapy may be necessary during TPN administration. Ongoing assessments include blood glucose levels according to institution policy and monitoring for signs and symptoms of infection, hyperglycemia, and hypoglycemia. When TPN therapy is begun, the rate is increased gradually to the prescribed rate to help prevent hyperglycemia. When it ends, the rate is gradually decreased to prevent hypoglycemia.

When nutritional solutions contain final concentrations exceeding 10% dextrose or 5% protein, they must be administered via a CVAD. When final concentrations are less than 10% dextrose or 5% protein, they may be administered through a peripheral vein. This is referred to as peripheral parenteral nutrition (PPN). PPN is a short-term intervention because it does not provide adequate nutrition over an extended period. Some states allow LVN/LPNs to initiate PPN.

The entire health care team must be involved in TPN or PPN therapy. The pharmacist, dietitian, HCP, and nurse communicate in a team conference to discuss the assessment, plan, and outcome criteria. Many institutions have nutrition teams that assess the appropriateness of TPN or PPN for individual patients.

Home Intravenous Therapy

As health care costs continue to rise, patients are using more alternatives to hospitalization. Subacute care, skilled nursing care in long-term care facilities, and home health care are growing. Home IV therapy allows many patients the benefit of early discharge and the ability to accomplish health care in the privacy and comfort of their own homes. Some home health agencies employ nurses to instruct patients and their families in the administration of home IV therapy (see “Home Health Hints”).

Home IV antibiotic therapy is becoming the method of choice in the long-term treatment of a number of infections, including bacterial endocarditis, osteomyelitis, and septic arthritis. Other patients with various diseases may choose to receive TPN, chemotherapy, or IV pain medications at home. The health team can assess patients and their families for their ability to manage home IV therapy.
Home Health Hints

Before discharge:
• If IV therapy is to be continued after hospital discharge, assist the RN in teaching the patient and caregiver the skills to oversee the IV therapy.
• Obtain a referral for a home care nurse to continue monitoring and teaching after discharge.
• Teach the patient and caregiver the effects and side effects of any medication, along with signs and symptoms to report to the home care nurse or HCP.
• Provide resource and contact information to patient and caregiver.
• Work with the RN or case manager to determine supplies and equipment needed for home IV therapy.

At home:
• Instruct the patient to refrain from smoking for at least 30 minutes before IV insertion to prevent vasocnstriction and ensure successful venipuncture.
• Instruct the patient to keep the IV site dry. If showering is permitted, instruct the patient to cover the IV with plastic (such as a grocery bag) and seal with tape on both ends to prevent water from entering the site.
• Assist the patient and caregiver to identify a safe place to store supplies. Note that some solutions or medications require refrigeration.
• Provide a biohazard container. The nurse is responsible for returning filled boxes to the home health agency for disposal.

REFLECTIONS ON MRS. BROWN

Think again about Mrs. Brown from the beginning of the chapter. She will need monitoring of I&O, daily weights, and close monitoring of her IV infusion. You should anticipate that serum electrolytes, BUN, and creatinine laboratory studies will be ordered. When initiating the infusion, use care in application of a tourniquet because older skin is thin and bruising can occur. Choose a number 20- or 22-gauge cannula to start the infusion. Once it is started, continue to monitor weights and lung sounds because older patients can quickly go from fluid depletion to fluid overload (see “Gerontological Issues”).

CRITICAL THINKING

Mrs. Green
Consider the following when assessing the patient for an appropriate venipuncture site:
1. An 18-gauge cannula should be used for blood administration whenever possible.
2. The cannula should not be inserted in the arm that has the dialysis access site.
3. The cannula should be placed in the forearm. Hand veins are too small to accommodate the delivery of blood.

Mr. Rick
Your patient’s IV line is likely clotted. If it has been so for a long time, it will not be salvageable. Do not flush it because doing so can dislodge the clot into the circulation. Discontinue the IV and insert a new cannula.

Mrs. Gonzalez
1. The IV fluid may be leaking at the insertion site and flowing into the subcutaneous tissue, a problem known as infiltration or extravasation, depending on the type of drug infusing.
2. Consider whether the pain could be caused by the buildup of fluid under the skin. Compare the insertion site with the opposite limb.
3. If the IV solution has infiltrated, stop the infusion, discontinue the cannula, and restart the cannula in a new site.
4. “Patient reports pain at IV site in right arm; area is cool to touch and edematous in 4.5-cm area around site. Flow rate sluggish. Infusion discontinued; IV restarted in left arm with 22-gauge cannula with good blood return. Infusing well with no signs of infiltration.”
5. The RN or IV therapy nurse would be good resources.
Chapter 7  Nursing Care of Patients Receiving Intravenous Therapy

REVIEW QUESTIONS

1. Which is the best resource for the nurse who has a question about the process and implementation of IV therapy for a specific patient?
   1. An experienced nurse
   2. Institution policy
   3. The physician
   4. INS standards of practice

2. Which patients have a need for IV therapy? Select all that apply.
   1. An 88-year-old man admitted to the hospital with dehydration
   2. A 21-year-old woman with an eating disorder and severe weight loss
   3. A 58-year-old woman with pneumonia who has been unresponsive to oral antibiotics
   4. A 37-year-old man recovering from a fall and broken arm
   5. A 4-year-old brought to the emergency room because of prolonged vomiting
   6. A patient with fluid overload who requires fast-acting diuretic therapy

3. A patient requests that an IV not be initiated in his hand. Which site is the next best choice?
   1. Forearm
   2. Antecubital fossa
   3. Upper arm
   4. Lower extremity

4. Place the steps for insertion of a peripheral IV cannula in chronological order. Use all of the options.
   1. Put on gloves
   2. Check HCP’s order.
   3. Prepare insertion site.
   4. Label the dressing.
   5. Perform hand hygiene.
   6. Dilate the vein.
   7. Document the procedure.
   8. Insert the cannula.
   9. Stabilize the site with tape.

5. The nurse must initiate an infusion on a 21-year-old man who has a history of sclerosed veins due to IV drug abuse or misuse, and multiple tattoos over both his arms. What would be the best approach to be able to visualize and initiate a peripheral IV?
   1. Place the arm in a dependent position.
   2. Use a blood pressure cuff.
   3. Use the multiple tourniquet technique.
   4. Have another nurse hold the patient’s arm.

6. A patient receiving IV therapy via a central line develops hypotension, cyanosis, and dyspnea. The nurse notes a crack in the IV tubing. Which of the following actions should the nurse take first?
   1. Have the RN call the HCP.
   2. Clamp the tubing and administer oxygen.
   3. Raise the head of the bed.
   4. Slow the infusion and lay the patient flat.

7. Which of the following solutions can be administered with a blood component?
   1. Lactated Ringer’s solution
   2. D5/0.2% NS
   3. D5/0.45% NS
   4. 0.9% NS

8. While assessing a patient, the nurse notes a silicone catheter taped to his chest and can feel the catheter under the skin. This type of catheter would be a:
   1. Peripherally inserted central catheter
   2. Implanted port
   3. Tunneled catheter
   4. Nontunneled catheter

9. The HCP orders 5% dextrose in water at 100 mL per hour. What is the drip rate using tubing with a drop factor of 20? Round to the nearest whole number.
   Answer: ___ gtt per minute

10. A patient is to receive 1000 mL normal saline over 12 hours. How many milliliters per hour should be set on the EID?
    Answer: ___ mL per hour

Answers can be found in Appendix C.

Nursing Care of Patients With Infections

LINDA S. WILLIAMS

LEARNING OUTCOMES

1. List the links in the chain of infection.
2. Explain how to interrupt the routes of transmission for infections.
3. Describe the body’s defense mechanisms to fight infection.
4. Describe the principles of anti-infective medication administration.
5. Plan nursing care for a patient with an infection.
6. Describe nursing care that has been effective for an infection.

THE INFECTION PROCESS

A pathogen is an organism that causes disease in a host (an infected person). Colonization occurs when pathogenic microbes are present in the body without causing symptoms or a detectable immune response. Infection occurs when a microbe multiplies in a host. Infection with only an immune response (increased antibody level for the microbe) and no symptoms is a subclinical infection. An infectious disease causes signs, symptoms, and injury to the host.

To prevent infection, the links in the chain of events leading to infection must be broken (Fig. 8.1). However, if an infection does occur, treatment focuses on breaking the chain of infection to prevent its spread to others.

Reservoir

A reservoir is the place in the environment where infectious agents live, multiply, and reproduce so they can be transmitted to a susceptible host. A reservoir can be animate (e.g., people, insects, animals, and plants) or inanimate (e.g., water, soil, or medical devices).

Causative Agents

Microorganisms that cause infection include bacteria, viruses, fungi, protozoa, helminths, and prions (Table 8.1). The organisms that occur naturally in or on a particular body part are known as normal flora. They are usually harmless, or nonpathogenic, because they do not normally produce disease in a healthy person.

Normal flora are helpful to the human host. For example, intestinal flora (i.e. bacteria) assist in vitamin K production, a nutrient needed for normal blood clotting. However, if these same bacteria get into another area of the body, such as the blood, they may produce disease and are then referred to as pathogenic.

Bacteria

Bacteria are single-celled organisms. They may depend on a host or live and reproduce outside a host. Most bacteria produce cell walls that are susceptible to antibiotic effects. However, bacteria can mutate to survive.

Bacteria are named according to their shape (spherical [cococcus], rod [bacillus], and spiral [spirillum]) and classified according to their staining properties (Gram’s method, acid-fast staining). Bacteria respond to stains in one of three ways: Gram-positive bacteria stain purple; Gram-negative bacteria lose purple stain when exposed to alcohol but stain pink with a second dye; and acid-fast bacteria keep purple stain when an acid is applied.

Bacterial growth depends on oxygen, nutrition, light, temperature, and humidity. Aerobic bacteria, such as those found on the skin, need oxygen to live. Anaerobic bacteria, such as bacteria in the gastrointestinal (GI) tract, live without oxygen. Most bacteria that inhabit humans grow best at body temperature, 98.6°F (37°C).

Rod-shaped bacteria form spores that are thick walled and hard to kill. Spores remain in a resting state until

WORD BUILDING

pathogen: pathos—suffering + genes—producer of
Rickettsiae. Rickettsiae are a type of bacteria that must be inside living cells to reproduce. Rickettsiae vectors (living organisms that transmit disease) are infected fleas, ticks, mites, and lice that bite humans. Several diseases are caused by rickettsiae. Rocky Mountain spotted fever, caused by Rickettsia rickettsii, whose reservoirs (the places in nature where the organism usually lives and multiplies without causing disease) are rodents and dogs, is transmitted to humans by a tick bite.

Viruses
Viruses are organisms smaller than bacteria that depend on host cells to live and reproduce (see Table 8.1). Invaded host cells make more of the virus material. The new viral particles are then released either by destroying the host cell or by forming small buds that break away to infect other cells. When a virus enters a cell, it may immediately trigger disease or remain dormant (inactive) for years without causing illness. An example of this is human herpesvirus 3 (varicella zoster virus), which can cause disease quickly (chickenpox) or remain dormant for years, eventually erupting in the disease called shingles. Antibiotics are not effective against viruses. Antiviral drugs are used to decrease symptoms caused by viruses and to decrease the viral load (the number of viral cells in the patient’s blood).

Rickettsiae. Rickettsiae are a type of bacteria that must be inside living cells to reproduce. Rickettsiae vectors (living organisms that transmit disease) are infected fleas, ticks, mites, and lice that bite humans. Several diseases are caused by rickettsiae. Rocky Mountain spotted fever, caused by Rickettsia rickettsii, whose reservoirs (the places in nature where the organism usually lives and multiplies without causing disease) are rodents and dogs, is transmitted to humans by a tick bite.

Viruses
Viruses are organisms smaller than bacteria that depend on host cells to live and reproduce (see Table 8.1). Invaded host cells make more of the virus material. The new viral particles are then released either by destroying the host cell or by forming small buds that break away to infect other cells. When a virus enters a cell, it may immediately trigger disease or remain dormant (inactive) for years without causing illness. An example of this is human herpesvirus 3 (varicella zoster virus), which can cause disease quickly (chickenpox) or remain dormant for years, eventually erupting in the disease called shingles. Antibiotics are not effective against viruses. Antiviral drugs are used to decrease symptoms caused by viruses and to decrease the viral load (the number of viral cells in the patient’s blood).
Protozoa
Protozoa are single-celled parasitic organisms with flexible membranes that live in the soil and obtain nourishment from dead or decaying organic material (see Table 8.1). Protozoa infect humans through fecal–oral contamination or through ingestion of food or water contaminated with cysts or spores, through host-to-host contact, or by the bite of a mosquito or other insect that has previously bitten an infected person.

Helminths
Helminths are wormlike parasitic animals: roundworms, flatworms, tapeworms, pinworms, hookworms, and flukes. Disease transmission occurs through skin penetration of larvae or ingestion of helminth eggs. Trichinosis (caused by the roundworm Trichinella spiralis) is a disease caused by eating raw or undercooked meat of pigs or wild animals that contain Trichinella larvae.

Prions
Prions are transmissible pathogenic agents. They cause abnormal folding of normal cellular proteins known as prion proteins. These prion proteins are found mainly in the brain. Brain damage results from the abnormal folding of prion proteins. Prion diseases have long incubation periods, cause no inflammatory response, progress rapidly, and are fatal. In humans, they include classic and variant Creutzfeldt-Jakob disease, and in animals, bovine spongiform encephalopathy (so-called mad cow disease) and chronic wasting disease.

Mode of Transmission
Once the causative agent exits the reservoir, a means of transfer to a susceptible host is needed. Transmission of microorganisms occurs through direct contact, indirect contact, or through the air. Understanding the modes of transmission of a particular disease allows you to use the appropriate means of personal protection without using unnecessary supplies that increase costs.

Direct Contact
Direct transmission occurs through touching, kissing, sexual contact, biting, or droplet spray into the eyes or on mucous membranes through sneezing, coughing, spitting, singing, or talking. Droplet spread is usually limited to 3 feet or less. Illnesses spread by direct transmission may include influenza, impetigo, scabies, conjunctivitis, pediculosis, herpes, C. difficile, and all sexually transmitted infections, including human immunodeficiency virus (HIV). Protect yourself and your patients from direct transmission with hand hygiene, aseptic technique, and use of personal protective equipment (PPE) such as gloves, surgical masks, goggles, gowns, and booties. PPE is selected and used based on the task to be performed and the applicable isolation precautions (standard precautions and/or transmission-based precautions; see the Infection Prevention Guidelines discussion later in the chapter).

Indirect Contact
Indirect transmission is either vehicleborne or vectorborne. Vehicleborne transmission is the spread of an infectious organism by contact with a contaminated object, such as a toy, soiled bedding, dressings from a wound, surgical instruments, water, food, and biological products such as blood, serum, plasma, tissues, and organs. Vehicleborne illnesses include conjunctivitis, trichinosis, HIV, and hepatitis A, B, C, D, and E. Vehicle transmission can be avoided through proper hand hygiene, thorough cleaning of the patient environment, and provision of clean water and food supplies.

Vectorborne transmission is the spread of infectious organisms through a living source other than humans, such as an insect, flea, mouse, or rat. Diseases spread through vectors include malaria, plague, and Lyme disease. Vector transmission can be reduced with insect repellants, a avoidance of infested areas, and rodent control.

Airborne
Airborne transmission is different from droplet transmission (see direct contact discussed earlier) because the particles floating in the air are much smaller, remain suspended in the air for a long time, and may travel long distances. Airborne organisms can be inhaled or deposited on the mucous membrane of a susceptible host. Measles, chickenpox, and tuberculosis (TB) are transmitted by airborne transmission. airborne transmission is prevented with the use of high-efficiency particulate air (HEPA) respirators (also known as a TB mask). HEPA respirators filter the tiniest particles from the air unlike surgical masks, which can allow such particles to pass into the respiratory system of a host. Institutions provide individual-fit testing and training for HEPA respirator use for each health care worker.

---

**BE SAFE!**

If you provide care for patients with suspected or confirmed diseases that are spread through airborne transmission, such as TB, be sure you have your own fit-tested HEPA mask to wear. Do not use other masks because they do not provide adequate protection. If you cannot obtain your own fit-tested mask, you should never enter the patient’s room.
Multiple Modes of Transmission

Many diseases have multiple modes of transmission requiring a variety of protective techniques. For example, chickenpox is transmitted by direct contact, indirect contact, and airborne transmission. It is no wonder that 80% to 90% of susceptible persons exposed to it develop the disease.

Portal of Entry

To produce disease, organisms must gain entry into a susceptible host. Routes of entry into a susceptible host include the respiratory tract, skin (usually nonintact), mucous membranes, GI tract, genitourinary tract, and placenta. Once the organism enters the host, it may lead to disease, depending on the condition of the host and many other factors, such as the virulence (ability to produce infection) of the organism.

Susceptible Host

The body has many defense mechanisms to prevent infection. A breakdown in these defenses increases the possibility of infection. Factors that increase susceptibility to infection are very young age, old age, malnourishment, immunocompromised, chronic disease, stress, burns, and invasive procedures (see "Gerontological Issues").

Portal of Exit

The portal of exit is the route through which the infectious agent leaves the host, who has become a reservoir for infection: respiratory tract, skin, mucous membranes, GI tract, genitourinary tract, blood, open lesions, or placenta.

THE HUMAN BODY’S DEFENSE MECHANISMS

Skin and Mucous Membranes

Intact skin and mucous membranes are the body’s first line of defense against infection. Preventing skin dryness and cracking with lotion keeps the skin intact so organisms do not have an entry point. Oral mucous membranes have many layers, making it difficult for organisms to enter the body. The skin has acidic (pH <7) properties that render some organisms unable to produce disease. For example, many bacteria prefer an alkaline (pH >7) environment for reproduction. The body also has an abundance of normal flora that impairs the growth of pathogens both on the skin and in the GI tract.

Cilia

Cilia are hairlike structures lining the upper respiratory tract mucous membranes that protect the lungs. Cilia trap mucus, pus, dust, and foreign particles to prevent them from entering the lungs. Then the cilia push the trapped particles up to the pharynx with wavelike movements for expectoration.

Gastric Juices

Gastric juices inside the stomach are very acidic (pH 1 to 5). This acidic environment destroys most organisms that enter the stomach.

Immunoglobulins

Immunoglobulins are proteins found in serum and body fluids. They may act as antibodies to destroy invading organisms and prevent the development of infection. Antibodies are the proteins produced by B lymphocytes when foreign antigens of invading cells are detected. Antigens are markers on the surface of cells that identify cells as being the body’s own cells (autoantigens) or as being foreign cells (foreign antigens). Antibodies combine with specific foreign antigens on the surface of the invading organisms, such as bacteria or viruses, to control or destroy them. Antigens are neutralized or destroyed by antibodies in several ways. Antibodies can initiate destruction of the antigen, neutralize toxins released by bacteria, promote antigen clumping with the antibody, or prevent the antigen from adhering to host cells.

Leukocytes and Macrophages

Leukocytes (white blood cells [WBCs]) are the primary cells that protect against infection and tissue damage. There are five types of leukocytes:

- Neutrophils are phagocytic cells that focus on bacteria and small particles.
- Monocytes become macrophages and are mainly phagocytic on tissue debris and large particles.
- Lymphocyte functions include antigen recognition and antibody production.
- Basophils respond to inflammation from injury.
- Eosinophils destroy parasites and respond in allergic reactions.

After recognizing a foreign antigen, neutrophils and macrophages engulf and digest it, a process known as phagocytosis. The macrophages move the antigen fragments to

Gerontological Issues

Infection and Older Adults

Fever is not a common sign of an infection for an older adult. This difference among older adults may cause significant delay in providing appropriate treatment and care. Be alert for the following signs of infection in older patients:

- Behavioral change, such as pacing or irritability
- Masking of the symptoms of infection by a noncommunicable disease (For example, the inflammation and pain of degenerative joint disease may make it difficult for a patient to recognize an infection in an affected joint.)

**WORD BUILDING**

**phagocytosis:** phagein—to eat + cytos—cell + osis—condition
their surface to be recognized by T lymphocytes to further stimulate action of the immune system. Phagocytes ingest and destroy bacteria, damaged or dead cells, cellular debris, and foreign substances.

**Lysozymes**
Lysozymes are bactericidal enzymes present in WBCs and most body fluids such as tears, saliva, and sweat. These enzymes dissolve the walls of bacteria, destroying them.

**Interferon**
If an invading organism is a virus, WBCs and fibroblasts release interferon (a group of antiviral proteins). Interferon helps destroy infected cells and inhibits production of the virus within infected cells. Tumor cell growth may also be inhibited by interferon.

**Inflammatory Response**
The inflammatory response occurs with an injury to the body. This response can be caused by pathogens, trauma, or other events causing injury to tissues. Infection may or may not be present.

**Vascular Response**
The first step of the inflammatory process is local vasodilation, which increases blood flow to the injured area. Pathogenic organisms can trigger the first step of the inflammatory process. Increased blood flow creates redness and heat at the injury. The increase in blood flow brings more plasma to the area to nourish tissue and carry waste and debris away.

**Inflammatory Exudate**
The second step of the inflammatory process is increased permeability of the blood vessels, which allows plasma to move out of the capillaries and into the tissues. Swelling occurs, resulting in pain from pressure on nearby nerve endings.

**Phagocytosis and Purulent Exudate**
The final step of the inflammatory process is the destruction of pathogenic organisms and their toxins by leukocytes. During this process, a purulent exudate (pus) may form that contains protein, cellular debris, and dead leukocytes.

**Immune System**
The immune system is the body’s final line of defense against infection (see Chapter 18). Immune cells and lymphoid tissue work with the body’s other defense mechanisms. The immune system is a finely tuned network of specialized parts that function together to protect the body from in invasion by pathogenic organisms. When this network breaks down, infection can result.

**Infectious Disease**

**Localized Infection**
Localized infection is caused by an increase of microbes in one area that triggers the inflammatory response. Manifestations of a local infection include pain, redness, swelling, and warmth at the site. Pain is most severe when the infection occurs in closed cavities. Redness and swelling are seen when surface structures are involved. Warmth may be felt at the site. Body temperature may rise to produce an antimicrobial effect.

**Sepsis**
Sepsis is an immune system response to a serious infection. It can be fatal due to the systemic inflammatory response syndrome (SIRS) that occurs from chemicals that are released to fight the infection. This inflammation can damage organ systems and cause them to fail. Septic shock occurs with decreased blood pressure (see Chapter 9). Visit www.survivingsepsis.org or www.ihi.org/explore/Sepsis.

**Laboratory Assessment**
A Gram stain, using gentian violet, helps bacteria be better viewed under a microscope for identification. Gram-positive bacteria turn purple, and Gram-negative bacteria become pink. A culture and sensitivity (C&S) identifies an illness-causing organism and determines which antibiotic would be most effective for treatment. Organisms in the culture specimen are grown on a laboratory plate and identified within 24 to 48 hours. The organism is then exposed to several antibiotics to determine to which antibiotics the organism is sensitive.

A serum antibody test measures the reaction to a certain antigen. A positive result for this test does not always mean that an active infection is present. It can simply mean there has been an exposure to the antigen, so it is not as accurate as a culture.

A complete blood count with differential (CBC with diff) is usually obtained when an infection disease is suspected. The levels of the five leukocytes are measured. Elevations in specific leukocytes occur based on the type and severity of the pathogen.

Erythrocyte sedimentation rate (ESR, sed rate) is an early screening test for inflammation but not a definitive test for infection. During the inflammatory process, red blood cells (RBCs) become heavier. The ESR measures in millimeters per hour the speed at which the RBCs settle in a tube. The faster the settling (due to heavier RBCs), the greater the inflammation.

Other tests such as x-rays, computed tomography (CT), and magnetic resonance imaging (MRI) are helpful in identifying abscesses (walled-off infections). Skin tests diagnose infections. For example, the purified protein derivative (PPD) skin test screens for TB (see Chapter 31).

**Immunity**
Immunity is the ability of the body to protect itself from disease (see Chapter 18). There are several types of immunity:

- Natural immunity occurs in species and prevents one species from contracting illnesses found in another species.
• Innate immunity is genetic; hereditary immunity is that which a person is born with.
• Acquired immunity is obtained either actively or passively through exposure to an organism, from a vaccine, or from an injection of immunoglobulins (antibodies) or is passed from mother to baby. Visit www.cdc.gov/vaccines to view vaccine schedules.

Types of Infectious Diseases
Communicable diseases are discussed in the chapters related to the body system they affect. For HIV, see Chapter 20; for respiratory diseases, see Chapter 31; for hepatitis, see Chapter 35.

Infectious Mononucleosis (Epstein-Barr Virus)
Infectious mononucleosis (IM) is caused by the Epstein-Barr virus (EBV), a herpes virus. EBV is spread through intimate contact with saliva of an infected person. IM is mainly diagnosed in adolescents or young adults. Most adults become infected with EBV and develop antibodies to it. EBV remains in the body for a lifetime.

The incubation period for IM is 4 to 6 weeks. Symptoms include fever, severe sore throat, generalized lymphadenopathy (enlarged lymph nodes in two different sites other than inguinal nodes) that last 1 to 4 weeks. The spleen enlarges 50% of the time. Occasionally, a rash develops that is similar to the rash seen with measles. Signs and symptoms, as well as diagnostic tests, confirm IM. Lymphocyte levels are elevated and positive mono spot and heterophile antibody tests confirm IM.

No specific treatment is needed for IM. Antiviral drugs are not effective. Symptoms are treated as needed with supportive care. Fatigue may last for months, and rest is important. Complications are rare.

INFECTION CONTROL IN THE COMMUNITY

Many levels of organizations work closely together to control communicable diseases. The World Health Organization (WHO) and the Centers for Disease Control and Prevention (CDC) teach standards to prevent and control diseases and monitor disease outbreaks. Local health departments teach how to prevent and control the spread of disease. Community immunization programs have helped reduce communicable diseases.

Although requirements vary from state to state, most elementary schools require some proof of childhood immunization. Many colleges also require or recommend immunization to help control the outbreak of diseases such as measles and meningitis. In addition, educating the public about the importance of hand hygiene, the CDC’s respiratory hygiene/cough etiquette measures, immunization, clean water, safe food handling techniques, and safer sex precautions in preventing the spread of disease is essential.

NURSING CARE TIP
For infection control, teach the CDC’s Cover Your Cough campaign instructions to patients and family members who have a cough, congestion, rhinorrhea, or increased respiratory secretions:
• Cover your mouth and nose with a tissue when you cough or sneeze.
• Put your used tissue in the wastebasket.
• If you don’t have a tissue, cough or sneeze into your upper sleeve, not your hands.
• Wash hands frequently with soap and water for 20 seconds, or use an alcohol-based hand cleaner.
• If asked, put on a facemask to protect others.

Both hospital and home health care nurses provide infection control teaching for the patient with an infection and his or her family. Techniques used should be specific to the interruption of the transmission of the particular disease. This may include the use of disposable dishes, utensils, and gloves, and proper disposal of contaminated items.

INFECTION CONTROL IN HEALTH CARE AGENCIES

If upon admission to a hospital or health care agency a patient already has an infection, it is referred to as a community-acquired infection. An infection that develops as a result of a patient’s stay in the hospital is called a hospital-acquired infection (HAI). The host’s condition plays a major role in whether an infection is acquired. Patients in the hospital are commonly debilitated, malnourished, or immunocompromised. Multiple antibiotic therapy also increases susceptibility to other types of infection and promotes the resistance of pathogens to antibiotics. Therefore, the risk of developing a HAI is high. Some areas within an institution tend to have an increased number of HAIs, such as intensive care, neonatal, dialysis, oncology, and burn units. Patients in these areas tend to undergo more invasive procedures and are debilitated, increasing susceptibility to infection.

Several pathogens are commonly responsible for causing HAIs:
• Escherichia coli (E. coli) is the most common pathogen causing hospital-acquired urinary tract infections (UTIs). E. coli normally lives in the healthy intestinal tract of humans. E. coli can be spread by the patient, by the
unwashed hands of a health care worker, or through contaminated food and water.

- *Staphylococcus aureus* (known as staph) is the most common pathogen causing hospital-acquired surgical wound infections. Staph usually lives in the nose and on the skin of healthy people.

- *Pseudomonas aeruginosa* is the most common pathogen in hospital-acquired pneumonia. It is found in soil, around water, and in the health care setting around sinks, water, irrigating solutions, and nebulizers on respiratory equipment.

**Hand Hygiene**

What is the single most effective way to prevent and control the spread of infection? Effective hand hygiene! This easily removes the transient organisms that cause most HAIs that result from cross-transmission. Most of these organisms are transmitted via the hands of health care providers (HCPs). Hands must be cleansed before and after every patient contact to help prevent the direct transmission of organisms (Fig. 8.2). The use of gloves decreases the transmission of organisms, but CDC guidelines also require hand washing before and after glove use because hands may still become contaminated. Did you know that patients may also transmit organisms with inadequate hand hygiene? Teach them the importance of hand hygiene after handling their own secretions. Offer your patients hand hygiene at meals and throughout the day!

**BE SAFE!**

The Joint Commission’s 2014 National Patient Safety Goal for preventing infection is as follows: Use the hand cleaning guidelines from the Centers for Disease Control and Prevention or the World Health Organization. Set goals for improving hand cleaning. Use the goals to improve hand cleaning (© The Joint Commission, 2013. Reprinted with permission.).

You are responsible for using appropriate hand hygiene in the health care setting. Hand hygiene can include either the use of hand washing or an alcohol-based hand rub, although soap and water are needed to remove *C. difficile*. For visibly soiled hands, wash with soap and water. Using alcohol-based hand rubs is preferred to kill bacteria in many cases and may increase adherence to protocols by saving time and reducing dry skin from the washing. For an informative presentation, visit www.cdc.gov/handhygiene/download/hand_hygiene_supplement_minus_notes.pdf or www.cdc.gov/features/handhygiene.

**Hand Washing**

Proper hand washing requires wetting the hands with warm—not hot—water, soaping, and lathering, with at least 20 seconds of rubbing your hands together (sing “Happy Birthday” song twice), covering all surfaces. Interlace your fingers to cleanse between them, rub your nails against your palms to clean under the nails, and then rinse your hands with fingertips pointed downward under running water. Dry your hands with clean disposable paper towels. Use the paper towel to turn off the faucet. Use only facility-supplied lotions because others may reduce the effectiveness of soap or break down latex gloves (water-based lotion only). Apply lotion to your hands to prevent drying and cracking in which infection could develop (CDC, 2013).

**Alcohol-Based Hand Rubs**

Apply specified amount of the hand rub to the palm of one hand. Rub both hands together, covering all surfaces until the hands are completely dry to ensure the alcohol has evaporated. Do not wash off hand rub.

**Asepsis**

The concept of *asepsis* (freedom from organisms) is important for all health care workers who have direct or indirect patient contact. For hospitalized patients, the most common sites for infection are the genitourinary tract, respiratory tract, bloodstream, and surgical wounds. Be aware of patients at risk of developing infections and protect them with aseptic techniques.
Medical Asepsis

Medical asepsis is commonly referred to as clean technique. The goal is to reduce the number of pathogens or prevent the transmission of pathogens from one person to another. Frequent, proper hand hygiene is one of the best ways to achieve this goal. The use of gowns, gloves, masks, and protective eyewear or rooms with special ventilation may also be helpful (Fig. 8.3). Disinfectants and precautions as defined by the CDC are also crucial tools. Techniques used should be appropriate to interrupt the spread of the known pathogen. As part of medical asepsis, you should keep your own body and clothing clean to prevent spread of infection to patients, yourself, and your family (Box 8-1).

Surgical Asepsis

Surgical asepsis (sterile technique) refers to an item or area that is free of all microorganisms and spores. Surgical asepsis is used in surgery and to sterilize equipment. Items can be subjected to intense heat or chemical disinfectants to destroy all organisms. The use of pressurized steam sterilizers, called autoclaves, kills even the most powerful organisms. Some equipment cannot be exposed to moist heat, so gas sterilizers are used instead. After these items are sterilized, they are dated, packaged, and sealed. Once a package is opened or outdated, it is no longer considered sterile.

Infection Prevention Guidelines

CDC guidelines for infection control and isolation precautions are used in hospital and health care agency policies. CDC and agency guidelines are continuously updated and should be followed for your patients’ and your own protection. Current CDC guidelines for isolation precautions in hospitals include two tiers of precautions: standard precautions and transmission-based precautions (Table 8.2). Visit www.cdc.gov/hicpac/2007IP/2007isolationPrecautions.html for more details.

Box 8-1 Guidelines to Prevent the Spread of Infection to Patients, Self, and Family

- Bathe daily and wear a clean uniform/clothing every day.
- Keep your natural fingernail tips less than 1/4 inch long, and do not wear artificial nails. Studies have shown that long fingernails and artificial nails harbor harmful bacteria and have transmitted infections to patients that have sometimes resulted in death.
- Avoid wearing rings and bracelets at work because they harbor organisms.
- Cleanse your stethoscope at least daily and in between patient use with alcohol. Vancomycin-resistant Enterococcus bacteria have been cultured from stethoscopes in a hospital setting.
- Use hand hygiene between each patient contact. The use of an alcohol-based hand gel or hand washing is recognized as the single most important action to take to prevent spread of infection.
- Follow prescribed isolation precautions for your protection, as well as that of the patient.
- Perform hand hygiene before going home to prevent transfer of bacteria to your home.
- Remove your uniform in a contained area of your home to launder it, and bathe/shower when you come home from work. This will decrease the spread of antibiotic-resistant bacteria to your home and your family. Keep your nursing shoes clean and stored away from the rest of the family.
### TABLE 8.2 STANDARD PRECAUTIONS AND TRANSMISSION-BASED PRECAUTIONS

#### Standard Precautions
Use standard precautions for all patient care. Combine standard precautions with transmission-based precautions as needed based on the patient’s illness.

| Hand hygiene | Use alcohol-based hand rub or wash hands with non-microbial soap unless specifically contraindicated before and after using gloves, between patients, and between procedures on the same patient. |
| Gloves | Wear gloves before contact with any body fluids or substances. Change gloves after each use. |
| Mask, eye protection, face shield | Use personal protective equipment for patient care if splashes or sprays of blood or body fluids are likely. |
| Gown | Wear gown to protect skin/prevent soiling of clothing for patient care if splashes or sprays of blood or body fluids are likely. |
| Occupational health and bloodborne pathogens | Dispose of sharps properly. Do not recap needles. |
| Patient care equipment | Clean reusable equipment before reuse. Dispose of single-use items properly. |
| Linen | Handle linen to avoid clothing contamination. |
| Patient placement | Use private room for infectious patients. |

#### Transmission-Based Precautions

##### Airborne Precautions
*Examples: measles, tuberculosis, varicella (chickenpox, shingles)*

| Patient placement | Provide private room with regulated airflow. Keep door closed. |
| Respiratory protection | Do not enter room if susceptible to measles or chickenpox unless no caregivers who are immune are available. If susceptible, wear a fit-tested (N95) disposable respirator. Do not enter room of patient with tuberculosis (TB) unless wearing a fit-tested (N95) disposable respirator. Have patient with TB also wear surgical mask during times that care is performed. Offer visitors an N95 respirator per agency policy. Teach patient respiratory hygiene/cough etiquette. |
| Patient transport | Limit patient transport to essential purposes. Place surgical mask on patient (may not contain all TB organisms) |

##### Droplet Precautions
*Examples: adenovirus, diphtheria (pharyngeal), Haemophilus influenzae (epiglottitis, meningitis, pneumonia), influenza, mumps, mycoplasma pneumonia, Neisseria meningitidis (meningitis, pneumonia, pertussis, pneumonic plague, rubella, group A streptococcus.)*

| Patient placement | Provide private room or separation greater than 3 feet between the infected patient and other patients and close privacy curtain. |
| Respiratory protection | Wear mask upon entering patient area. Teach patient respiratory hygiene/cough etiquette. |

<tr>
<th>Transmission-Based Precautions</th>
<th>Patient transport</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Limit patient transport to essential purposes. Place surgical mask on patient.</td>
</tr>
</tbody>
</table>

**Contact Precautions**

**Examples:** cellulitis, *Clostridium difficile*, skin infections (diphtheria, herpes simplex virus, impetigo, pediculosis, scabies, conjunctivitis, viral hemorrhagic infections (Ebola, Lassa, or Marburg), herpes zoster

| Patient placement | Provide private room or place with patient with same infection and no other infection. |
| Hand washing, gloves, gown | Protect self and others from contaminated items. |
| Patient transport | Limit patient transport. |
| Patient care equipment | Dedicate the use of noncritical patient care equipment to a single patient. |

### Standard Precautions

Standard precautions are used in the care of all patients. These precautions require you to assume that all patients are infectious regardless of their diagnosis and to use personal protective equipment (PPE). Standard precautions apply to blood, secretions, excretions, open skin, mucous membranes, and all body fluids, excluding sweat. All patients with draining wounds or secretions of body fluids are considered infectious until an infection is confirmed or ruled out. Using PPE such as gloves, gowns, masks, goggles, face shields, along with hand hygiene helps prevent the spread of infection to healthcare workers and other patients.

### Prevention of Respiratory Tract Infections

Hospital-acquired pneumonia has been linked with the highest infection mortality rate. Patients who are at highest risk for pneumonia are those with endotracheal, nasotracheal, or tracheostomy tubes because these invasive tubes bypass the normal defenses of the upper respiratory tract. Strategies to prevent infections such as ventilator-associated pneumonia (VAP) are “bundled” together so nurses remember to use these strategies. For more information on VAP bundles, visit [www.cdc.gov/HAI/vap/vap.html](http://www.cdc.gov/HAI/vap/vap.html).

### Prevention of Genitourinary Tract Infections

The most common HAI is a UTI. Patients with urinary catheters are at greatest risk for this. The urinary tract is sterile, but insertion of a catheter into the bladder may allow organisms to enter it. Institutional policies on appropriate use of urinary catheters differ, so follow your agency’s policy. Appropriate reasons for use of a urinary catheter may include urinary obstruction, a neurogenic bladder condition, shock, and palliative care.

Indwelling urinary catheters should be removed as soon as possible. For patients who need long-term catheter use, intermittent catheterization is preferred because it significantly reduces the risk of infection. Using strict aseptic technique while inserting and caring for the catheter in the health care agency is imperative. The catheter tubing must be securely anchored to the patient’s leg, according to agency protocol, so it does not move in and out of the urethra. This is because movement can encourage or cause infections to enter the sterile urinary tract.

### CRITICAL THINKING

**Who Is at Greatest Risk of Infection?**

- Which of the following patients is at greatest risk for infection and why?

1. Mr. Ashland, age 55, is hospitalized for a hernia repair. He is overweight and has adult-onset diabetes.
2. Mrs. Burrows, age 72, is hospitalized for a broken hip. She is thin, frail, has dementia, and has undergone placement of a urinary catheter.
3. Jackson Dunn, age 22, is hospitalized for a major surgery. Jackson is thin and small.

Suggested answers are at the end of the chapter.

### Transmission-Based Precautions

Transmission-based precautions are used for patients with specific communicable diseases that can be transmitted to others. These precautions add an additional layer of protection to the standard precautions.

---

**Suggested answers:**

1. Mr. Ashland, age 55, is hospitalized for a hernia repair. He is overweight and has adult-onset diabetes.
2. Mrs. Burrows, age 72, is hospitalized for a broken hip. She is thin, frail, has dementia, and has undergone placement of a urinary catheter.
3. Jackson Dunn, age 22, is hospitalized for a major surgery. Jackson is thin and small.
The closed urinary drainage system seal should never be opened. If intermittent irrigation is ordered, sterile technique must be used to protect both ends of the system from contamination. The drainage bag should be positioned so that it is never higher than the level of the bladder to prevent backflow of urine into the bladder, which could contaminate the sterile urinary tract. If an indwelling urinary catheter and a drainage system are used long term, the catheter and the entire system should be changed regularly using sterile technique. All long-term indwelling urinary catheters are considered colonized. Standards in home care differ from institutional care because patients are generally at lower risk of infection within their own environment.

Remember that the most crucial point at which bacteria may enter the patient is during insertion of the catheter, so excellent sterile technique is required. The urinary tract is highly vascular (many blood vessels close to the surface), so that an infection in this tract can easily result in bacteremia (bacteria in the blood), which can then progress to sepsis (systemic inflammatory response to infection), a potentially life-threatening condition. For more information on prevention of UTIs in adults, visit www.kidney.niddk.nih.gov/kudiseases/pubs/utiadult/index.htm.

**CRITICAL THINKING**

**Mr. Carson**

- While working in an extended care facility, you see Mrs. Brandt, nursing assistant, wheeling Mr. Carson to activities. He has a long-term urinary catheter. The urine bag is hung on the arm of the wheelchair. What is your responsibility in this situation as a team member?

Suggested answers are at the end of the chapter.

**Prevention of Surgical Wound Infections**

The initial dressing for surgical wounds is applied in the operating room using sterile aseptic technique. Postoperative orders indicate when to change the dressing. Monitor the wound with each dressing change for signs of infection.

**LEARNING TIP**

Do you know what antibiotics kill? Bacteria, not viruses! See the b in bacteria and antibiotics.

That is how you can remember it. Antibiotics are not effective against viral infections such as colds or the flu. Taking antibiotics to treat viral infections increases the risk for antibiotic-resistant “superbugs.” Nurses play a vital role in educating people about this growing problem so that no one requests antibiotics for viral infections.

**Methicillin-Resistant Staphylococcus Aureus**

A serious antibiotic-resistant infection, MRSA, is difficult to treat and has a high mortality rate. It affects mainly older adults and the chronically ill. Vancomycin HCL is an IV antibiotic used to treat MRSA. However, experts fear that the S. aureus bacterium will further mutate and become resistant to all antibiotics. A few isolated cases of this mutation have been documented worldwide. The risk that resistant organisms will spread is real, which will return us to preantibiotic days when S. aureus was a killer.

**Vancomycin-Resistant Enterococci**

Vancomycin-resistant enterococci (VRE) infections are common. Although enterococci are normal flora in the GI and female genital tracts, VRE are a pathogenic strain. VRE are transmitted via direct or indirect contact. Patients at risk for VRE infections include those with indwelling urinary or central venous catheters, the immunocompromised or critically ill, those receiving multiple antibiotics or vancomycin therapy, surgical patients, and those with extended hospital stays. Preventive VRE measures focus on proper hand hygiene, education of HCPs, aggressive infection control methods, and restricting use of vancomycin. Patients with VRE should be isolated, and CDC and agency isolation policies strictly followed. Treatment involves combination antibiotic therapy.

**ANTIBIOTIC-RESISTANT INFECTIONS**

Antibiotic-resistant infections, such as methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant enterococci (VRE), are an urgent worldwide health concern. It is up to each of us to understand how to prevent antibiotic resistance. The CDC’s Get Smart: Know When Antibiotics Work campaign aims to educate prescribers and individuals on the appropriate use of antibiotics (www.cdc.gov/getsmart/index.html). This education explains that most upper respiratory infections do not require antibiotic treatment, so avoiding the use of antibiotics for viral infections (common cold or flu) is important. Teaching patients to take all prescribed medications exactly as ordered is also vital. Resistant or organisms are difficult to treat, can spread easily to others and may result in death. So preventing resistance is a major concern for HCPs.

**BE SAFE!**

Catheters should be used only when necessary because of the morbidity (sickness) and mortality (death) associated with infections that can develop from them. The continued need for an indwelling catheter should be monitored daily, and the catheter should be discontinued as quickly as it is no longer needed.
Once an infecting causing or germs and the affected body system have been identified, the appropriate medication can be selected and treatment be given (Table 8.3). The drug of choice must be able to destroy (or control) the pathogen:

- Antibiotics treat bacterial infections, not viruses, fungi, helminths, or prions.
- Antiviral medications treat viral infections, but their use is aimed at symptom control rather than cure.
- Antifungal drugs are available for fungal infections, but cure may require extended use.

Cost effectiveness is another concern when selecting a medication. Newer anti-infectives can be very expensive.

Antibiotics can be classified as either bactericidal or bacteriostatic. Bactericidal agents kill bacteria, whereas bacteriostatic agents inhibit or retard bacterial growth, leaving the final destruction of the bacteria up to the infected host’s immune system. Bacteriostatic agents may be less helpful for the patient who is immunocompromised.

**BE SAFE!**

Whenever preparing to give an antibiotic, especially for the first time, ask what allergies a patient may have. Patients may have allergies to one antibiotic group that prevents the use of chemically similar drugs. Therefore, all allergies should be reported to the HCP.

Many antibiotics are metabolized by the liver and excreted by the kidneys. Disorders of these organs may require lower doses. Antibiotic levels fluctuate greatly depending on organ function, age, sex, health, and other factors. Antibiotic serum peak and trough levels (highest and lowest blood levels) may need to be monitored according to agency protocol to ensure therapeutic levels and to prevent toxicity.

**Antibiotic-Associated Diarrhea**

Antibiotic therapy may cause antibiotic-associated diarrhea (AAD) because antibiotics upset the delicate balance of natural microbiota normally found in the intestine. Any antibiotic can cause AAD, but ampicillin, cephalosporins, and clindamycin are the most common. Antibiotics destroy helpful bacteria along with harmful bacteria. With fewer good bacteria to keep potentially harmless bacteria in check, the harmful bacteria that are resistant to the antibiotic used increase in number. These bacteria can produce toxins that harm the intestinal wall and cause inflammation. Watery bowel movements result. When AAD occurs, the antibiotic therapy may be stopped, and the diarrhea usually resolves. For severe diarrhea, colitis (colon inflammation), or pseudomembranous colitis, metronidazole (Flagyl) or vancomycin (Vancocin) is given. A **probiotic** (a substance with health-promoting effects, such as yogurt in this case) may help prevent AAD.

**Clostridium Difficile**

*Clostridium difficile* is a Gram-positive bacterium, sometimes found normally in the intestine, that can cause infection. It can be one of the most serious causes of AAD and is a growing concern for the CDC. When normal gut microbiota has been destroyed, *Clostridium difficile* can overgrow and release toxins that cause diarrhea of 20 or more stools daily, fever, bloating, and abdominal pain. Healthy people typically do not have *Clostridium difficile* overgrowth. It can occur after antibiotic therapy, usually in those who are hospitalized or in nursing homes, with older adults being at greatest risk (see “Evidence-Based Practice”). *C. difficile* overgrowth can lead to pseudomembranous colitis, a serious and sometimes life-threatening condition with fever, diarrhea, and abdominal pain. The bacteria are transmitted by the fecal-oral route from touching feces-contaminated surfaces. Lidless toilets increase the risk of *C. difficile* environmental contamination by spraying organisms during flushing, so their use is discouraged (Best, Sandoe, & Wilcox, 2012). Hand washing is essential to reduce its spread, as alcohol based rubs are not effective. To treat diarrhea caused by *C. difficile* infection (CDI), the antibiotic treatment is stopped, and metronidazole (Flagyl) or vancomycin (Vancocin) given. Recurrence of the infection can occur.

**EVIDENCE-BASED PRACTICE**

**Clinical Question**

Are probiotics effective in preventing *C. difficile*?

**Evidence**

A systematic review and meta-analysis of 23 randomized controlled trials that included 4213 patients, moderate-quality evidence suggests that probiotics are both safe and effective for preventing *C. difficile*-associated diarrhea by 64% in patients who are not immunocompromised or severely debilitated.

**Implications for Nursing Practice**

Probiotics can be useful in preventing *C. difficile*. Nurses can encourage patients who are prescribed antibiotic therapy to consult an HCP, pharmacist, or dietitian about the use and appropriate dosage of probiotics.

</table>
**Fecal Microbiota Transplantation**

Fecal transplant (fecal microbiota transplantation) is a treatment that is growing in usage for treating *C. difficile* infection (CDI), primarily when other treatments have failed. The purpose of fecal transplant is to restore the missing healthy bacteria in the intestine and restore balance to gut health. It has shown dramatic results in restoring health and quality of life to those with CDI, often rapidly. Patients who have been gravely ill from recurrent CDI can be infection-free within days after the treatment. Understanding the role the gut microbiota play in our health is leading to the exploration of other uses for fecal transplant. Conditions such as Crohn’s disease, ulcerative colitis, inflammatory bowel syndrome, and even rheumatoid arthritis are being explored for this treatment.

Donated feces from a healthy person, often a family member, is transplanted into a patient via colonoscopy, nasogastric or nasojejunal tube, retention enema, or oral capsules. The multilayered capsules contain only the bacteria processed from the feces that dissolve in the small intestine. A stool substitute, made from purified intestinal bacterial cultures, is being studied for use in recurrent CDI. This synthetic stool bacterial mixture, RePOOPulate, has been shown to be effective and is more acceptable to patients.

**Nursing Care**

Nurses are responsible for administering medications correctly and for teaching patients the importance of taking these medications properly (Box 8-2). Follow these general guidelines and consult drug references for further information before giving anti-infectives:

- Note all patient allergies, and inform the HCP.
- Obtain ordered samples for culturing before starting ordered anti-infectives, so culture accuracy is not affected.
- Monitor and report to HCP any side effects or signs of allergic response, especially anaphylactic reactions, and peak and trough results.
- Observe and report to HCP any signs of superinfection (one that occurs as a result of antibiotic use). For example, oral thrush (white raised lesions on tongue) may develop because antibiotics disrupt the normal GI tract flora.

---

<td></td>
</tr>
</tbody>
</table>

*Teaching*: notify HCP at the first sign of yellow skin, dark urine, or pale stools (signs of liver damage). Vfend causes blurry vision about 20 minutes after dose and patient should not drive.

---

**Box 8-2 Patient Teaching**

**Anti-Infective Medications**

- Stress to the patient and family the need to take all of the medication exactly as prescribed.
- Explain that stopping treatment before the prescription is finished, even if the patient feels better, increases the risk of relapse and the growth of antibiotic-resistant organisms.
- Explain the signs and symptoms of side effects (allergic and nonallergic) to watch for and what to do about them.
- Explain when to call the primary care provider to report signs and symptoms.

---

**BE SAFE!**

Always review medication doses and compare them with the normal dose of the medications before giving them to keep your patient safe and protect your nursing license. You are responsible for any medication you give, even if the dose was ordered incorrectly and you were following the order. If the dose is outside the normal range, do not give the drug. Consult with the registered nurse, pharmacist, or your supervisor, who should contact the ordering HCP for clarification.

---

**NURSING PROCESS FOR THE PATIENT WITH AN INFECTION**

**General Infections**

**Data Collection**

Early detection of signs and symptoms can help provide early treatment to prevent major complications and reduce costs. Providing emotional support to the patient is also important.
(see “Patient Perspective”). Patients who are prone to infection because of immunosuppression should take special precautions to prevent infection (Box 8-3).

**Patient Perspective**

**Jeff: Emotions Experienced With Chronic Infection**

It was back! I wasn’t sure I could deal with it one more time. I’ve been hospitalized four times with this same infection (cellulitis) in my leg. It feels like I’ve lost my life. I can’t count on being able to do anything or go anywhere because the infection just keeps coming back.

My left leg is now all swollen, red, discolored, and very painful. I can tell when I’m infected by more than the pain in the leg. I feel weak, kind of spacey, and once I passed out. I’m so sick of going to the emergency room—waiting forever to get admitted, having all the IV starts and blood draws. With these infections, I’ve had a PICC (peripherally inserted central catheter) line twice. I’ve been sent home on IV antibiotics, sometimes for weeks at a time. I’ve learned how to hang my own IV antibiotics; in fact, I’ve learned much more than I ever wanted to know.

My cellulitis is associated with chronic lymphedema, causing swelling in my legs. I’m working hard to keep the swelling down so the infection doesn’t recur. Wish me luck and keep giving me psychosocial support during your nursing care. I’m not sure how I will be able to deal with this much longer.

**Box 8-3 Patient Education**

**Prevention of Infection in Older, Debilitated, or Immunocompromised Patients**

- Wash your hands often, using proper technique.
- Avoid crowds or anyone with an infection.
- Stay well nourished because food helps keep the immune system healthy.
- Have a flu shot yearly and a pneumonia shot as recommended by your primary care provider.
- Wash raw fruits and vegetables thoroughly, cook food thoroughly, and store food safely to prevent food poisoning. (Note: If you are severely immunocompromised, raw foods, soft cheeses, and yogurt may be contraindicated because of the risk of bacterial infection.)
- If your immune system is depressed, notify your primary care provider if you have an elevated temperature, even if you have no other symptoms. People with depressed immune function cannot mount the usual immune response to infection, and a low-grade fever may be the only sign of infection.

**CRITICAL THINKING**

**Mr. Cheevers**

Mr. Cheevers is admitted to the hospital for IV antibiotic therapy. He states that he has no allergies. One hour after the infusion begins, you happen to meet the nursing assistant coming down the hall with a blanket. He casually says, “Mr. Cheevers is very cold. I’m taking him a blanket. He is also restless and a bit short of breath.” What is your responsibility in this situation?

Suggested answers are at the end of the chapter.

**Nursing Diagnoses, Planning, and Implementation**

**Risk for Infection related to external factors**

**EXPECTED OUTCOME:** The patient will remain free from symptoms of infection.

- Follow current hand hygiene guidelines to reduce spread of infection.
- Use standard precautions and transmission-based precautions to prevent the transmission of organisms.
- Observe and report signs of infection such as redness, warmth, and fever promptly, especially for neutropenic patients because they do not have normal inflammatory response and low-grade fever is often the only sign.
- Monitor laboratory values of WBC counts and cultures because they correlate to patient’s immune function for planning care.

**Evaluation**

If interventions have been successful, the patient remains free from symptoms of infection.

**Imbalanced Nutrition: Less Than Body Requirements related to problems eating or digesting food**

**EXPECTED OUTCOME:** The patient will maintain ideal body weight for height and weight and eat a balanced diet.

- Identify and provide foods patient enjoys with pleasant presentation because patient will be more likely to try eating enjoyable foods in a clean, odor-free environment.
- Explain and ensure that a balanced diet with protein, fatty acids, and vitamins is available and should be eaten. These nutrients are needed for healthy immune system function.
- Monitor and document patient intake to provide accurate nutritional assessment.
- Provide antiemetics, as ordered, to control nausea and vomiting and improve nutritional intake.

**Evaluation**

If interventions have been effective, patient’s body weight will be maintained within ideal body weight range and patient will eat a balanced diet.
Ch 8  Nursing Care of Patients With Infections  129

Deficient Knowledge related to disease process and treatment

**EXPECTED OUTCOME:** The patient will describe therapy and carry out treatment.

- Explain infection and how to prevent infection. Patients’ understanding of how infections occur helps them in controlling their risk of infection.
- Recommend responsible use of antibiotics to prevent resistant organisms.
- Explain medications, side effects, and symptoms to report to promote adherence to treatment and safe medication use.
- Teach patients how to participate in their own care and have them assist in the development of their plan of care to promote adherence to treatment.

Evaluation

If interventions have been effective, the patient will state understanding of therapy and plan and carry out treatment plan.

Respiratory Tract Infection

**Data Collection**

Patients with respiratory tract infections may have a cough, a congested or runny nose, a sore throat, chest congestion, or chest pain. The throat may be reddened, or there may be white patches in the back of the throat. Lung sounds can include crackles, rhonchi, or wheezing. Ask patients if they have a productive cough and the amount, frequency, and color of the sputum. A sputum culture is obtained to identify the presence of pathogenic organisms for appropriate treatment.

**Nursing Diagnoses, Planning, and Implementation**

**Risk for Infection related to external factors**

**EXPECTED OUTCOME:** The patient will remain free from symptoms of infection.

- Encourage coughing and deep breathing to keep airways clear and prevent atelectasis.
- Provide oral care with toothbrush or suction-type toothbrush (see Chapter 2) and fluoride toothpaste regularly to remove plaque, which has been found to contribute to pneumonia development. (Toothettes do not remove plaque.)
- Encourage fluids if not contraindicated. Dehydration is associated with dry, sticky secretions that are difficult to cough up.
- Provide pain relief so patient will take deep breaths.
- Elevate head of bed 30 degrees or more when a tube feeding is infusing to prevent aspiration pneumonia.
- Use sterile water rather than tap water from faucet for oral care for immunocompromised patients to prevent hospital-acquired pneumonia.

**Evaluation**

If interventions have been effective, oxygen saturation will be above 90%, with report of decreased dyspnea. Respirations will not be labored, and patient will be free of signs and symptoms of infection.

Gastrointestinal Tract Infection

**Data Collection**

The symptoms of GI tract infections may include nausea, vomiting, diarrhea, cramping, and anorexia. Signs of dehydration from fluid loss are reported. Stool cultures may be ordered.

**Nursing Diagnoses, Planning, and Implementation**

**Risk for Infection related to external factors**

**EXPECTED OUTCOME:** The patient will remain free from symptoms of infection.

- Encourage fluid intake to replace fluid lost during fever, vomiting, and diarrhea.
- Follow standard precautions, especially for older and immunocompromised patients, to prevent the spread of *C. difficile*, which usually does not cause infection in healthy adults.
- Teach hand hygiene with antimicrobial soap and water if contact with *C. difficile* spores is likely because alcohols, chlorhexidine, iodophors, and other antiseptic agents are not effective in destroying *C. difficile* spores.

**Evaluation**

Patient will be free of infection and nausea, vomiting, diarrhea, cramping, anorexia, and dehydration if interventions have been successful.

Genitourinary Tract Infection

**Data Collection**

Symptoms of a UTI include voiding urgency, frequency, burning, flank pain, change in urine color, foul urine odor, and confusion or change in mental status in older adults. Monitor frequency, amount, color, and odor of the urine. Urinalysis and urine cultures may be ordered.

**Nursing Diagnoses, Planning, and Implementation**

**Risk for Infection related to external factors**

**EXPECTED OUTCOME:** The patient will remain free from symptoms of infection.

- Do not request and avoid use of urinary catheters unless no other options are available because patients are more likely to develop a UTI.
- Use sterile technique for inserting urinary catheters to prevent HAIs.
- Avoid contamination when emptying urinary catheter bags to prevent health care–acquired infections.

**Evaluation**

If interventions have been effective, the patient will have normal urine output without symptoms of UTI.
CRITICAL THINKING

Mrs. Sampson
1. Hand hygiene reduces the microorganisms on the nurse’s hands to help reduce their transmission from patient to patient. This helps prevent exposure to pathogens and infection.
2. Risk for infection.
3. Reverse isolation, the goal of which is to protect the patient from exposure to organisms rather than to protect others from exposure to the patient.

Who Is at Greatest Risk of Infection?
1. Mr. Ashland has two risk factors: chronic disease and probably stress.
2. Mrs. Burrows has many risk factors, including older age, debilitated condition, probable malnourishment, probable stress, and an invasive procedure. This patient is at greatest risk.
3. Jackson has three risk factors: probable stress, possible malnourishment, and an invasive procedure.

Mr. Carson
1. Ask the nursing assistant about the urinary bag placed above the patient’s bladder. Explain that the bag should always stay below the level of the bladder both for proper drainage and for infection control.
2. Assist the nursing assistant in repositioning the bag properly.
3. Let Mr. Carson’s primary nurse knows about the potential backflow of urine so that he can be assessed in the next few days for signs of a bladder infection.

Mr. Cheever
Mr. Cheever may be experiencing signs of allergic reaction to the medication. The fact that he has no history of allergy is no guarantee that he is not experiencing one now. If allergy is suspected, the IV should be stopped. He needs to be evaluated immediately and the primary care provider notified. Epinephrine should be on hand to treat the patient for anaphylaxis. The primary nurse needs to be alerted to the situation in the event that it worsens. Later, the nursing assistant can be instructed about the signs of an allergic response.

REVIEW QUESTIONS

1. Place the links in the chain of infection in their proper order of occurrence in causing an infection.
   1. Portal of entry
   2. Causative agents
   3. Mode of transmission
   4. Portal of exit
   5. Reservoir
   6. Susceptible host

2. The nurse prepares to bathe a patient. Which of the following is the MOST important technique for the nurse to use during patient care to prevent infection transmission?
   1. Wear gloves.
   2. Wear a gown.
   3. Wash hands.
   4. Wear a mask.

3. The nurse is caring for a patient who is on bed rest. Which of the following nursing actions should the nurse include in the plan of care to help maintain the body’s first line of defense against infection?
   1. Help the patient cough and deep-breathe.
   2. Apply lotion to clean skin.
   3. Give an antibiotic as ordered.
   4. Help the patient void.

4. The LPN/LVN has taken patient temperatures. Which of the following patient temperature readings would be the PRIORITY for the LPN/LVN to report to the RN?
   1. Temperature 97°F (36.1°C) for an older patient with hypertension
   2. Temperature 98.9°F (37°C) for a first-day post-operative patient
   3. Temperature 99.6°F (37.5°C) for a patient with neutropenia
   4. Temperature 100°F (37.7°C) for a patient with appendicitis

5. The nurse is to give a newly ordered antibiotic to a patient with a wound infection. Which of the following is ESSENTIAL to do before giving the medication?
   1. Check all patient allergies.
   2. Check the patient’s temperature.
   3. Change dressing and note wound appearance.
6. The nurse is caring for a patient with an indwelling urinary catheter. Which of the following is the MOST important action for the nurse to use to prevent a hospital-acquired UTI from developing in this patient?
   1. Ensure an adequate intake of IV and oral fluids.
   2. Use clean technique for catheter insertion.
   3. Position the drainage bag higher than bladder level.
   4. Maintain a closed urinary drainage system.

7. The nurse is caring for a patient receiving an antibiotic. Which of the following statements indicates to the nurse that the patient understands the general principles of appropriate antibiotic use?
   1. “I’ll take this until I start feeling better.”
   2. “I have pills left over from the last time I had this infection.”
   3. “I’ll take all of this as it says to on the medication label.”
   4. “I take only half of a pill to reduce the cost of the pills.”

LEARNING OUTCOMES

1. Explain the pathophysiology of shock and compensatory mechanisms.
2. Identify the etiology, signs, and symptoms for each of the four categories of shock.
3. Describe therapeutic measures for shock.
4. List data to collect when caring for patients in shock.
5. Plan nursing care for patients in shock.
7. Identify findings that demonstrate a positive response to therapeutic measures for shock.
Shock is a life-threatening medical emergency that requires rapid intervention by the health care team. A person in shock is in a state of circulatory collapse. Without immediate treatment, organ damage and death occur.

Shock is defined as inadequate tissue perfusion in which there is insufficient delivery of oxygen and nutrients to the body's tissues and inadequate removal of waste products from these tissues, or, more simply, an imbalance between oxygen supply and demand. The decrease in tissue perfusion leads to impaired cellular metabolism, which in turn leads to tissue hypoxia. Tissue hypoxia results in hypoperfusion of vital organs and cell death. All body systems are affected by reduced oxygen supplies. The resulting injury to the body can be treated in the early stages of shock, but if shock is prolonged, it leads to irreversible cell damage and death. By the time blood pressure drops, cellular and tissue damage have already occurred. Therefore, it is important to identify patients at risk for shock and carefully monitor them to detect early signs and symptoms.

**PATHOPHYSIOLOGY OF SHOCK**

Tissue perfusion and blood pressure are maintained in the body by three mechanisms: (1) adequate blood volume, (2) an effective cardiac pump, and (3) effective blood vessels. The body is able to compensate for failure of one of these mechanisms by making a change in one or both of the other two. Shock occurs when compensatory mechanisms fail, resulting in inadequate tissue perfusion. Common causes of shock include inadequate cardiac output caused by heart failure, a sudden loss of blood volume resulting from hemorrhage, or a sudden decrease in peripheral vascular resistance caused by anaphylaxis (a life-threatening allergic reaction); sepsis (an infection that has spread to the bloodstream); or neurologic alterations.

**Metabolic and Hemodynamic Changes in Shock**

When blood pressure falls, the body responds by activating the sympathetic nervous system. Epinephrine and norepinephrine are released from the adrenal medulla and increase cardiac output by causing the heart to beat faster and stronger. Blood is shunted away from the skin, kidneys, and intestines to preserve blood flow to the brain, liver, and heart. Epinephrine, cortisol, and glucagon raise blood glucose levels to supply cells with fuel. Stimulation of the renin-angiotensin-aldosterone system from decreased cardiac output causes vasoconstriction and retention of sodium and water to decrease further fluid loss. Respiratory rate increases to deliver more oxygen to the tissues. Together these compensatory responses produce the classic signs and symptoms of the initial stage of shock: tachycardia, tachypnea, restlessness, anxiety, and cool, clammy skin with pallor. If oxygen delivery remains inadequate, signs and symptoms of progressive and irreversible shock are seen (Table 9.1).

UNIT TWO  Understanding Health and Illness

Inadequate tissue blood flow causes an important change in cellular metabolism. When cells are deprived of oxygen, they shift from aerobic metabolism to anaerobic metabolism to continue to receive nutrition and energy. **Anaerobic metabolism** is an inefficient form of metabolism that can supply the energy needs of the cell for only a few minutes. After that, the body’s metabolic rate and temperature begin to fall as a result of reduced energy production.

Anaerobic metabolism results in the production of lactic acid as an unwanted byproduct. Unless the lactic acid can be circulated to the liver and thus removed from the bloodstream, the blood becomes increasingly acidic. **Acidosis**, which is a decrease in blood pH below 7.35, is one of the classic signs of shock.

**Effect on Organs and Organ Systems**

Why would prolonged shock cause extensive damage to the organs and organ systems (Table 9.2)? It is due to the inadequate blood flow that results in tissue ischemia and injury. Because blood is shunted a way from the kidneys early in shock to save fluid and provide oxygen to vital organs, the kidneys are commonly injured first. The kidneys can tolerate reduced blood flow for about 1 hour before cells in the kidneys die from a lack of oxygen and nutrients. If there is widespread damage to the kidneys, complete renal failure is likely. Renal failure resulting from inadequate blood flow to the kidneys can be prevented and treated by replacing lost fluids.

### CRITICAL THINKING

**Classic Signs of Shock**

- What is the cause and compensatory purpose of each of the classic signs of shock: tachycardia, tachypnea, oliguria, pallor, and cool, clammy skin?

* Suggested answers are at the end of the chapter.

### LEARNING TIP

Tachycardia is a compensatory mechanism that is usually the first sign of shock. When a patient develops sustained tachycardia, it is a signal that the patient's condition is changing. Older patients cannot tolerate tachycardia very long because their ability to adapt to stress is reduced.

Consider the cause of the tachycardia. For example, a surgical patient who develops tachycardia can be hemorrhaging and should be assessed for bleeding. With internal hemorrhaging, there might not be any visible signs of bleeding. Changes in vital signs can be the only evidence. Provide prompt intervention, such as applying direct pressure to an area of hemorrhage, and implement the physician's orders immediately.

### CRITICAL THINKING

**Anaerobic Metabolism**

- Why is anaerobic metabolism necessary and helpful if it produces the complication of metabolic acidosis?

* Suggested answers are at the end of the chapter.

Several organs of the gastrointestinal (GI) system can be injured early in shock. Inadequate circulation to the intestines can result in injury of the mucosa and can even cause paralytic ileus (paralysis of the intestine). **Toxemia** can result when the body absorbs normally occurring bacteria and endotoxins from inside the bowel into the circulation. The liver can be injured by both ischemia and toxins created by the shock state as blood is circulated through it for cleansing. Signs and symptoms of liver injury include decreased production of plasma proteins, abnormal clotting (because clotting factor production by the liver is impaired), and elevated serum levels of ammonia, bilirubin, and liver enzymes.

- **Tachycardia**: tachy—fast + cardia—heart
- **Tachypnea**: tachy—fast + pnea—breathing

**WORD BUILDING**
The immune system is also affected by shock, leaving the body vulnerable to infection. Also, if the liver has been damaged, it is unable to assist the immune system in providing defense.

The body attempts to preserve blood supply to the heart and brain because these are vital organs that require a continuous supply of oxygen. Shock places extra demands on the heart itself, creating a situation in which the heart is in extra need of oxygen at a time when oxygen supplies are already low. When the myocardium (the middle layer of the heart wall) receives inadequate oxygenation, cardiac output decreases, and shock worsens. The pumping ability of the heart can be further depressed by acidosis, toxins released into the blood from ischemic tissues, or ischemia-induced dysrhythmia (abnormal heart rhythm). If the brain is deprived of circulation for more than 4 minutes, brain cells die from a lack of oxygen and glucose. As a result, prolonged shock can result in brain death.

The immune system is also affected by shock, leaving the body vulnerable to infection. Also, if the liver has been damaged, it is unable to assist the immune system in providing defense.

The body attempts to preserve blood supply to the heart and brain because these are vital organs that require a continuous supply of oxygen. Shock places extra demands on the heart itself, creating a situation in which the heart is in extra need of oxygen at a time when oxygen supplies are already low. When the myocardium (the middle layer of the heart wall) receives inadequate oxygenation, cardiac output decreases, and shock worsens. The pumping ability of the heart can be further depressed by acidosis, toxins released into the blood from ischemic tissues, or ischemia-induced dysrhythmia (abnormal heart rhythm). If the brain is deprived of circulation for more than 4 minutes, brain cells die from a lack of oxygen and glucose. As a result, prolonged shock can result in brain death.

### COMPLICATIONS FROM SHOCK

Acute respiratory distress syndrome (ARDS), disseminated intravascular coagulation (DIC), and multiple organ dysfunction syndrome (MODS) are three especially grave conditions that can follow a prolonged episode of shock. Patients with ARDS experience respiratory failure and typically require high levels of supplemental oxygen and mechanical ventilation. DIC results from ischemic damage to the endothelial lining of blood vessels. The formation of multiple tiny thrombi (blood clots), microscopic debris, and depletion of tissue-clotting factors cause abnormal bleeding and additional tissue damage. DIC itself can cause shock and death. MODS is a major cause of death following shock. When an organ has inadequate perfusion, it fails, which can increase the rate of failure of other organs. It usually begins with respiratory failure, followed by failure of the kidneys, heart, liver, and finally cerebral and GI function.

### LEARNING TIP

To understand what disseminated intravascular coagulation means, define each of the words and then put the definitions together.

**Disseminated**: scattered or widespread
**Intravascular**: intra = inside + vascular = vessels
**Coagulation**: clotting

Put together, these definitions tell you that DIC is scattered, widespread clotting inside the vessels.

At first, hemorrhage does not seem likely in light of a clotting problem, but if you think about what is occurring, it makes sense. When many clots form throughout the body in response to stressors, few clotting factors remain available to form the clots needed to prevent hemorrhage. As a result, hemorrhage is a risk in DIC.

### CLASSIFICATION OF SHOCK

The four types of shock are classified by their cardiovascular characteristics (Table 9.3):

- **Hypovolemic** shock is caused by a decrease in the circulating blood volume.
- **Cardiogenic** shock is caused by cardiac failure as a pump.
- **Extra-cardiac** obstructive shock is caused by a blockage of blood flow in the cardiovascular circuit outside the heart.
- **Distributive** shock is caused by excessive dilation of the venules and arterioles.

Most cases of clinical shock show only some components of each of these categories. However, this classification system is helpful in understanding shock. The hallmark characteristic, seen in all forms of shock, is a decrease in blood pressure usually below the level needed to provide enough blood to the tissues.
Hypovolemic Shock

Any severe loss of body fluid can lead to hypovolemic shock. Hypovolemic shock can be caused by dehydration; internal or external hemorrhage; fluid loss from burns, vomiting, or diarrhea; or loss of intravascular fluid into the interstitial space as a result of sepsis or trauma (physical injury caused by an external force). Heat exhaustion or heatstroke can also cause hypovolemic shock by excessive water loss through sweating. Clinical signs and symptoms include restlessness; pale, cool, clammy skin; tachycardia; tachypnea; flat, nondistended peripheral veins; decreased jugular vein circumference; decreased urine output; and altered mental status. The body is usually able to compensate for blood loss of less than 15%, or 750 mL. The initial symptom may only be tachycardia, although there can be an initial rise in systolic blood pressure, then a fall to below 80 mm Hg. At 20% to 25% blood loss, tachycardia and mild to moderate hypotension are present. With a loss of 40% or greater (2000 mL), all clinical signs and symptoms of shock are present. Volume loss might not be the only contributing factor to hypovolemic shock. The patient’s age, health status, and the time frame for losing the fluid can also be factors.

</table>
Cardiogenic Shock

Cardiogenic shock results when the heart fails as a pump. It is a medical emergency. Without treatment, mortality is high. Patients with cardiogenic shock have signs and symptoms similar to hypovolemic shock, except that they might also have distended jugular and peripheral veins, as well as other symptoms of heart failure, such as pulmonary edema. The presence of pulmonary edema is what differentiates cardiogenic shock from other forms of shock. Fluid therapy can contribute further to pulmonary edema, which can be life threatening. The main cause of cardiogenic shock is acute myocardial infarction (AMI) and myocardial ischemia. Examples of other causes are traumatic injury to the heart, myocarditis, cardiomyopathy, heart valve defects, endocarditis, or dysrhythmias.

Extracardiac Obstructive Shock

Extracardiac obstructive shock occurs when there is a blockage of blood flow in the cardiovascular circuit outside the heart. Several conditions can cause obstructive shock. Pericardial tamponade, which is the filling of the pericardial sac with blood, compresses the heart and limits its filling capacity. Tension pneumothorax is compression of the heart from an abnormal collection of air in the pleural space, which interferes with normal cardiac function. Acute pulmonary hypertension, a sudden abnormally elevated pressure in the pulmonary artery, increases resistance for blood flowing out the right side of the heart. All of these conditions decrease cardiac output, which can lead to shock. Tumors or a pulmonary embolism can also cause shock. Signs and symptoms of obstructive shock are similar to those of hypovolemic shock, except that jugular veins are usually distended.

Distributive Shock

Distributive shock occurs when peripheral vascular resistance is lost because of massive vasodilation of the peripheral circulation. Unlike hypovolemic shock in which there is an actual loss of blood volume, distributive shock occurs when the body’s fluid distribution is abnormally altered within the body. Distributive shock includes anaphylactic, septic, and neurogenic shock.

Anaphylactic Shock

Anaphylactic shock, the most severe type of distributive shock, occurs when the body has an extreme hypersensitivity reaction to an antigen. Death from anaphylactic shock can occur in minutes but is infrequent. Medical treatment must be sought immediately. Asthma or a delay in epinephrine injections can increase risk of death. Patients must be taught allergen avoidance techniques for safety (Box 9-1). Desensitization therapy to the allergen should be discussed with the health care provider.

Anaphylaxis occurs most commonly from food allergies such as shellfish or peanuts, insect stings, antibiotics (especially penicillins), anesthetics, contrast dyes, and blood products. The signs and symptoms are similar to those seen in hypovolemic shock. Additionally, patients can have symptoms specific to allergic reactions, including urticaria (hives), pruritus, wheezing, laryngeal edema (swelling of the larynx), angioedema (edema of skin, mucous membranes, or internal organs), and severe bronchospasm (narrowing of bronchi in the lungs). If conscious, patients can be extremely apprehensive and short of breath, and report a metallic taste.

Septic Shock

Sepsis is a serious bloodstream infection resulting from systemic infection and inflammation. This inflammation is the body’s response to serious illness and is known as the systemic inflammatory response syndrome (SIRS). Thus, sepsis is SIRS from an infection. Many cases of sepsis are caused by Gram-positive bacteria, although other bacteria, fungi, viruses, or parasites can be the cause. Septic shock, the most common type of distributive shock, results from severe sepsis. It is characterized by a low blood pressure despite fluid therapy.

Sepsis is the leading cause of death among intensive care patients. The incidence of sepsis doubled from 2000 to 2008 with a 17% mortality rate (Hall, Williams, DeFrances, & Golosinskiy, 2011). The 2012 Surviving Sepsis Campaign’s goal is to reduce the mortality rate from sepsis by 25% (see “Evidence-Based Practice” and www.survivingsepsis.org). Factors contributing to sepsis include older age, chronic illness, invasive procedures and devices, being immunosuppressed (e.g., HIV, chemotherapy, corticosteroids), antimicrobial resistant organisms, burns, and malnutrition (“Gerontological Issues”). Early diagnosis and rapid response are key to increasing survival for septic shock, especially in the vulnerable older adult population.

Gerontological Issues

The older adult population has less ability to fight infections, which places them at higher risk for sepsis. The sepsis rate for those aged 85 and over was about 30 times the rate for those under age 65 (Hall et al, 2011). Early recognition of shock signs is essential for successful treatment in this high-risk population.

SIRS is diagnosed when two or more of the following signs are present: abnormal body temperature (high
Neurogenic Shock

Neurogenic shock occurs when dysfunction or injury to the nervous system causes extensive dilation of peripheral blood vessels. It is a rarer form of shock and results most commonly from an injury to the spinal cord (referred to as spinal shock). It occurs because of factors that either stimulate the parasympathetic nervous system or block the sympathetic nervous system. Other causes include general anesthesia, fever, metabolic disturbances, and brain contusions and concussions.

Signs and symptoms include hypotension and altered mental status and, during the early phases, bradycardia and warm, dry skin. As shock progresses, however, tachycardia and cool, clammy skin develops.

THERAPEUTIC MEASURES FOR SHOCK

Because of the life-threatening nature of shock, immediate medical treatment is needed. The exact nature of the shock must be determined while interventions such as ventilatory and circulatory support are implemented (Table 9.4). Life-threatening symptoms must be treated immediately (Table 9.5). Medications that are used in shock are listed in Table 9.6. The order of interventions and testing is guided by the stability of the patient. Intervention priorities are as follows:

1. Airway
2. Breathing and respiratory support
3. Cardiovascular support
4. Maintenance of circulatory volume
5. Control of bleeding if present
6. Assessment of neurologic status
7. Treatment of life-threatening injuries

NURSING PROCESS FOR THE PATIENT IN SHOCK

Data Collection

Recognizing patients at risk for shock and being vigilant in monitoring their condition is vital. Early detection and prevention of shock in patients at risk for shock are the desired
goals. Rapid response teams can be helpful in providing quick assessment and management of patients at risk of developing shock.

For the patient in shock, assessment must be carried out quickly and should always start with ABCD: airway, breathing, circulation, and disability.

_Airway_ is checked for patency and opened as necessary. A compromised airway must be treated immediately with the head-tilt/chin-lift method, an oral or nasal airway, or endotracheal intubation.

_Breathing_ is checked for rate, depth, and symmetry of chest movement. The patient is observed for use of accessory muscles. Lung sounds are auscultated. Wheezing can be present in the patient with anaphylactic shock. Crackles can be found in the patient with cardiogenic shock or in the patient who has received too much IV fluid.

_Circulation_ is checked with blood pressure. A narrowing pulse pressure can be present before a drop in systolic pressure and indicates a decrease in cardiac stroke volume and peripheral vasoconstriction. Peripheral pulses are palpated. Tachycardia is the first sign of shock. However, patients on medications that block the sympathetic nervous system

</tbody>
</table>
response will not exhibit tachycardia. The pulse is assessed for quality; commonly it is weak and thready in a patient with shock. As shock progresses, the peripheral pulses become bradycardic or absent. A capillary refill greater than 3 seconds indicates inadequate circulation, although it has been found to be an unreliable indicator of shock in adults, especially older adults. Other observations regarding circulation include distended neck veins; skin that can be cool, pale, and diaphoretic; presence of cyanosis (bluish color of the skin and mucous membranes due to decreased oxygen in the blood); mucous membranes that can be pale and dry; and thirst. Rapidly scan the entire body for evidence of bleeding or other injuries. Palpation of the abdomen can reveal signs of internal bleeding, such as a tender, distended, boardlike abdomen.

TB = tuberculin; VS = vital signs.

**CRITICAL THINKING**

**Beta Blockers**

- A patient who takes a beta-blocker medication is being monitored for septic shock. What sign of shock do you understand will not be present in a patient taking a beta blocker?

Suggested answers are at the end of the chapter.

Disability is determined by the patient’s level of consciousness (LOC). A decrease in LOC indicates disability. This disability can range from lethargy to coma.

All four limbs are checked for circulation, sensation, and mobility (CSM). Bilateral responses are compared for equality. Circulation is assessed by palpating pulses for presence and quality. Sensation is determined by touching the patient’s hands and feet and asking what the patient feels and if there is any numbness or tingling. Mobility (motor ability) is assessed by having the patient move all four limbs and wiggle the fingers and toes. Have the patient push with his or her feet against your hands and squeeze two of your fingers to determine strength.
A head-to-toe approach can follow the primary ABCD assessment. The presence, severity, and location of pain or nausea and vomiting are noted. Body temperature is determined. Bowel sounds are auscultated to determine whether they are normal, absent, hyperactive, or hypoactive. When an indwelling urinary catheter has been placed, the color of the urine and the rate of urine output are noted.

Nursing Diagnoses, Planning, Implementation, and Evaluation

See Table 9.7 for a summary of shock. Also see “Nursing Care Plan for the Patient Experiencing Shock.”

CRITICAL THINKING

Mr. Hall

Mr. Hall, who is 58 years old, had an AMI 2 days ago. He is reporting chest pain (rated 10/10 on the pain rating scale) and difficulty breathing. Blood pressure 96/40, Pulse 110, Respirations 22. His SpO₂ is 89%. Crackles are heard on auscultation of breath sounds. The electrocardiogram shows an irregular and rapid heartbeat. He is restless and apprehensive.

1. Name three nursing priorities for Mr. Hall’s care.
2. With which members of the health team does the nurse anticipate collaborating?
3. What type of IV fluid and flow rate are appropriate for Mr. Hall?
4. What signs and symptoms indicate Mr. Hall is in cardiogenic shock?

Suggested answers are at the end of the chapter.

NURSING CARE PLAN for the Patient Experiencing Shock

**Nursing Diagnosis:** Ineffective Tissue Perfusion (renal, cerebral, cardiopulmonary, gastrointestinal, peripheral) related to hypovolemia or inadequate cardiac output or changes in circulatory volume or inadequate vascular tone possibly evidenced by altered level of consciousness, changes in skin color/temperature, tachycardia, reduced blood pressure, and decreased urine output.

**Expected Outcomes:** Patient will demonstrate adequate tissue perfusion as evidenced by warm dry skin, peripheral pulses strong, vital signs within normal parameters of baseline, breath sounds without adventitious sounds, and balanced intake and output, and patient will be alert and oriented to person, place, time within specified time frame.

**Evaluation of Outcomes:** Is patient’s skin warm/dry and peripheral pulses present/strong? Are vital signs within patient’s normal range? Are lung sounds normal, intake/output balanced, edema absent, pain/discomfort absent? Is patient alert and oriented?

**Intervention** Maintain airway and provide oxygen as ordered. **Rationale** Ensures adequate oxygenation and tissue perfusion. **Evaluation** Is \( \text{SpO}_2 \) > 95%? Are skin and mucous membranes pink? Are respirations between 12 and 20 per minute? Are lung sounds clear?

**Intervention** Monitor vital signs. **Rationale** Changes in vital signs, which indicate change in condition, can be detected early and treated promptly. **Evaluation** Is heart rate between 60 and 100 beats per minute? Is heart rhythm regular? Are peripheral pulses strong? Is systolic blood pressure greater than 100 mm Hg? Is patient alert and oriented \( \times 3 \)?

**Intervention** Monitor intake and output. **Rationale** Provides adequate cardiac output to perfuse tissues. Assesses renal function. Urine output is an indicator of renal function. **Evaluation** Is urinary output greater than 30 mL/hr?

**Intervention** Provide adequate fluid intake. **Rationale** Maintains volume. **Evaluation** Are mucous membranes moist? Is skin turgor less than 3 seconds?

**Intervention** Position patient appropriately (head elevated for patients with shortness of breath, increased intracranial pressure, mechanically ventilated). **Rationale** Proper positioning promotes circulation and helps prevent skin breakdown. **Evaluation** Is edema noted? Is skin breakdown noted?

**Intervention** Maintain body temperature with warmed IV fluids, room temperature, blankets. **Rationale** Recovery is aided by normal body temperature. **Evaluation** Is body temperature within normal limits?

**Intervention** Provide quiet, restful environment. **Rationale** Conserves energy and lowers tissue oxygen demands. **Evaluation** Is patient resting comfortably without anxiety?

**Intervention** Monitor for pain, and provide pain relief measures. **Rationale** Pain increases tissue demands for blood and oxygen. **Evaluation** Is patient pain free?

**GERONTOLOGICAL**

**Intervention** Change positions slowly. **Rationale** Age-related losses of cardiovascular reflexes can result in hypotension. **Evaluation** Is systolic blood pressure greater than 100 mm Hg?

**Nursing Diagnosis:** Decreased Cardiac Output related to reduced circulating blood volume, structural damage, or decreased myocardial contractility as evidenced by abnormal vital signs and irregular cardiac rhythm strip.

**Expected Outcomes:** Patient will have adequate cardiac output as evidenced by vital signs and cardiac rhythm within normal limits (WNL) within specified time frame.

**Evaluation of Outcomes:** Are blood pressure, heart rate, and cardiac rhythm within normal limits? Are nailbeds and/or skin pink? Is skin warm and dry?

**Intervention** Monitor heart rate and cardiac rhythm with electrocardiogram, and report abnormalities. **Rationale** Changes in heart rate and cardiac rhythm can be detected immediately and treated appropriately. **Evaluation** Is heart rate and rhythm normal?
**NURSING CARE PLAN** for the Patient Experiencing Shock—cont’d

**Intervention** Monitor skin/nailbed color, capillary refill, and peripheral pulses and report abnormalities.  
**Rationale** Inadequate perfusion is first evident in skin/nailbeds and peripheral pulses.  
**Evaluation** What color and temperature is the skin/nailbeds? Is capillary refill less than 3 seconds? Are peripheral pulses present?

**Intervention** Give cardiovascular medications and oxygen as ordered.  
**Rationale** Cardiac function can be supported with medications. Supplemental oxygen increases oxygenation of heart and tissues.  
**Evaluation** Is heart rate and rhythm normal?

**Intervention** Reduce myocardial oxygen demand by utilizing comfort measures to alleviate pain and anxiety, and by keeping the body at an appropriate temperature.  
**Rationale** Pain, anxiety, and cold all increase tissue demands for blood and oxygen, which increases the workload on the heart to supply it.  
**Evaluation** Is body temperature within normal limits? Is the patient free of pain and anxiety?

**GERONTOLOGICAL**  
**Intervention** Monitor perfusion by methods other than capillary refill such as skin temperature.  
**Rationale** Capillary refill is frequently delayed in the older adult population.  
**Evaluation** Is the body temperature within normal limits?

**Nursing Diagnosis:** Fear related to severity of condition and unknown outcome as evidenced by verbalization of fear (e.g., “Am I going to die?”)  
**Expected Outcome:** Patient will state fear is reduced after nurse provides information related to patient’s condition.  
**Evaluation of Outcome:** Does patient state fear is decreased?

**Intervention** Explore patient’s level of fear and knowledge of condition. Provide explanations for condition, procedures, and treatment.  
**Rationale** Knowledge allows a feeling of control and reduces fear.  
**Evaluation** Does patient state fear is reduced?

**Nursing Diagnosis:** Deficient Knowledge related to unfamiliar condition of shock as evidenced by verbalization of deficient knowledge (e.g., “I don’t understand what’s happening to me.”)  
**Expected Outcome:** Patient will explain shock and its treatment.  
**Evaluation of Outcome:** Can patient explain shock and how it is treated?

**Intervention** Identify patient’s ability to learn and barriers to learning.  
**Rationale** For learning, the patient must be stable and ready to learn.  
**Evaluation** Is patient alert and stable? Does patient indicate willingness to learn?

**Intervention** Provide patient-centered information on shock and treatment.  
**Rationale** Giving individualized information on topic meets patient’s need for understanding.  
**Evaluation** Can patient explain shock and purpose of treatment that patient is receiving?

**Intervention** Allow time for questions and clarification.  
**Rationale** Clarification ensures accurate information is learned.  
**Evaluation** Does the patient state accurate information?

**GERONTOLOGICAL**  
**Intervention** Speak slowly and clearly in a low tone/pitch.  
**Rationale** Older adults have difficulty hearing high-pitched tones.  
**Evaluation** Does the patient acknowledge when being spoken to?

**Intervention** Provide materials in large print.  
**Rationale** Visual changes that accompany aging can require a patient to use larger print materials.  
**Evaluation** Can the patient restate and/or read aloud information that has been given?

**Intervention** Involve family/caregivers in teaching.  
**Rationale** Family/caregivers can reinforce education provided.  
**Evaluation** Does family/caregivers verbalize understanding of material presented?
Understanding Health and Illness

LEARNING TIP
Here is a saying to help you remember blood pressure effects in shock: If they're 90 over 60, they're getting kind of sickly. Say it again! If they're 90 over 60, they're getting kind of sickly.

CRITICAL THINKING

Mrs. Neal

Mrs. Neal, who is 45 years old, came to the emergency room in severe hypovolemic shock after sustaining several bleeding wounds in an automobile accident. Her shock is resolving after receiving several transfusions and surgical repair of her injuries. She has just been admitted to the surgical unit for postoperative care.

1. What postoperative nursing assessments should be performed first?
2. How can patient-centered care be promoted during treatment?
3. Mrs. Neal’s family is alarmed by her condition. What interventions can be provided to decrease their anxiety?
4. What postoperative complications can develop in Mrs. Neal?
5. What documentation is appropriate for Mrs. Neal?

Suggested answers are at the end of the chapter.

CRITICAL THINKING

Classic Signs of Shock
Tachycardia is caused by decreased cardiac output and reduced tissue oxygenation. Its purpose is to increase cardiac output and oxygen delivery by causing more heartbeats to pump out blood from the heart.

Tachypnea is caused by decreased tissue oxygenation. Its purpose is to increase respirations so more oxygen is available for delivery to tissues.

Oliguria is caused by a reduced blood flow to the kidneys. Its purpose as a compensatory mechanism is to conserve as much fluid as possible to help maintain a normal blood pressure.

Pallor is caused by reduced blood volume or flow. When pallor results from compensation, it is due to peripheral vasoconstriction that occurs to shunt blood volume to the vital organs.

Cool, clammy skin is the result of decreased blood flow to the skin and the release of moisture (sweat) from the skin. The sympathetic nervous system causes these compensatory mechanisms; peripheral vasoconstriction shunts blood to the vital organs, and sweating cools the body in anticipation of the fight-or-flight response, which generates body heat when it occurs.

Anaerobic Metabolism
Anaerobic metabolism is the source of nutrition and energy for the cell that prevents cellular death when oxygen is not available. It is a short-term compensatory mechanism to save the cell until oxygen becomes a viable again.

SUGGESTED ANSWERS TO

CRITICAL THINKING

Beta Blockers
Tachycardia will not be present. Beta blockers block the response of the sympathetic nervous system, which is activated in shock.

Mr. Hall
1. Nursing priorities for Mr. Hall include adequate tissue perfusion, relief of chest pain and anxiety, and stabilization of cardiac rhythm and vital signs.
2. Health care provider and case manager.
3. Because Mr. Hall’s lung sounds reveal crackles, indicating fluid in the lungs, he should probably not be given IV fluids. He already has too much fluid for his heart to handle, and giving him more IV fluids could be life threatening. He should have an IV access for IV medications as needed.
4. Signs of cardiogenic shock include decreased blood pressure; increased heart and respiratory rates; cyanosis; decreased urine output; cool, pale skin; and decreased mental status.

Mrs. Neal
1. Data collection for respiratory and cardiovascular status, inspection of surgical wounds for bleeding and noting mental status and the need for pain relief should be performed first.
2. Develop a pain management plan to meet Mrs. Neal’s individualized needs. Identify her normal coping techniques to support their appropriate use. Provide explanations and teach as needed to keep patient informed for decision making. Advocate for her individualized needs such as nutritional needs.
Chapter 9  Nursing Care of Patients in Shock  145

SUGGESTED ANSWERS TO—cont’d

3. Explain the cause of shock and all interventions, rationales, and desired outcomes. Keep the environment calm, provide for privacy, and answer all questions in a matter-of-fact and reassuring manner. Allow Mrs. Neal’s family to visit.
4. Unrelieved pain, bleeding, infection, and respiratory complications are possible.

REVIEW QUESTIONS

1. The nurse is assisting with a patient experiencing shock in the emergency department. The nurse would recognize signs of compensation as resulting from which of the following mechanisms?
   1. Peripheral nervous system depression
   2. Central nervous system depression
   3. Sympathetic nervous system stimulation
   4. Parasympathetic nervous system stimulation

2. Which of the following findings would the nurse specifically anticipate during data collection for a patient experiencing anaphylactic shock? Select all that apply.
   1. Wheezing
   2. Hypotension
   3. Tachycardia
   4. Oliguria
   5. Urticaria
   6. Bronchospasm

3. The nurse would recognize which of the following conditions as the cause for decreased level of consciousness commonly found in patients with shock?
   1. Severe pain
   2. Endotoxins
   3. Cerebral edema
   4. Cerebral hypoxia

4. The nurse is contributing to the plan of care for an older adult patient at risk for cardiogenic shock. Which of the following interventions for Deficient Knowledge would the nurse include to help this older patient learn about this condition? Select all that apply.
   1. Involve family/caregivers in teaching.
   2. Monitor patient’s vital signs frequently.
   3. Provide materials in large print.
   4. Reinforce health promotion activities with the patient.
   5. Speak slowly and clearly in a low tone/pitch.

5. A patient with septic shock is receiving large amounts of crystalloid fluids. Which of the following findings would indicate to the nurse that the treatment is effective?
   1. decreased urine output
   2. increased heart rate
   3. clammy skin
   4. increased blood pressure

6. The nurse is contributing to the plan of care for a patient experiencing shock. Which of the following nursing diagnoses is most appropriate to include in this plan?
   1. Fatigue
   2. Ineffective Tissue Perfusion
   3. Ineffective Health Maintenance
   4. Hopelessness

7. A patient who is found lying in a pool of blood from a leg incision that has opened is restless and confused. The nurse calls for help and takes vital signs. Which of the following treatments for shock would the nurse anticipate being ordered first?
   1. Crystalloid IV fluids
   2. Oxygen
   3. Vasopressor medications
   4. One unit of packed red blood cells

8. The nurse is assigned to the team caring for the following patients. Which patient would be the priority for the nurse to see first?
   1. A patient who was in a motor vehicle accident with blood pressure 140/80 mm Hg, pulse 98 beats per minute, respirations 20 per minute.
   2. A patient who has a migraine with blood pressure 108/68 mm Hg, pulse 84 beats per minute, respirations 16 per minute.
   3. A patient who slipped and fell with blood pressure 112/74 mm Hg, pulse 68 beats per minute, respirations 14 per minute.
   4. A patient who is one day post-op with blood pressure 88/58 mm Hg, pulse beats 152 per minute, respirations 24 per minute.
9. Which of the following findings would indicate to the nurse that the therapeutic measures for a patient in shock have been effective?
1. Heart rate 110 beats per minute
2. SpO₂ 89%
3. Systolic blood pressure 118 mm Hg
4. Respiratory rate 22 per minute

10. The nurse is caring for a patient who is experiencing progressive shock. Place in correct order of occurrence the systolic blood pressure findings that the nurse obtained for this patient who progressed through the three stages of shock and is now in irreversible shock. Begin with compensated shock and use all options.
1. 56 mm Hg
2. 116 mm Hg
3. 86 mm Hg

Answers can be found in Appendix C.

Nursing Care of Patients in Pain

SHERIA GRICE ROBINSON, APRIL HAZARD VALLERAND, AND KAREN P. HALL

LEARNING OUTCOMES

1. Describe current definitions of pain.
2. Identify common myths and barriers to the effective management of pain.
3. Differentiate among addiction, physical dependence, and tolerance.
4. Explain current understanding about the basic physiology of the pain response.
5. Differentiate between nociceptive and neuropathic pain.
6. Perform a basic pain assessment.
8. Describe the three classes of analgesics and their uses.
9. Identify commonly used pain medication treatment modalities and their appropriate use.
10. Recognize appropriate use of nonpharmacological pain management techniques.

KEY TERMS

addiction (uh-DIK-shun)  
adjuvant (ad-JOO-vant)  
agonist (AG-un-ist)  
analgesic (AN-uhl-JEE-zik)  
antagonist (an-TAG-on-ist)

THE PAIN PUZZLE

Have you ever been in pain? If you have, then you know that pain is unpleasant. Not only does it hurt physically, but it can also make us feel emotionally sad or angry and lead to social isolation. Pain is a sensory and emotional experience that can affect every aspect of the person’s being and how he or she relates to the environment. Pain management is the most common reason patients seek medical advice. However, despite the widespread nature of the problem and the millions of dollars spent on care, pain often remains untreated or undertreated. Nurses can make a difference in pain management.

Nurses often worry about overmedicating patients and may think that they are “doing good” (beneficence) or “doing no harm” (nonmaleficence) by withholding medication from a patient whom they do not believe is in pain (see “Ethical Considerations—Controlling Pain” on DavisPlus). So how can we know what pain is, and how can we truly tell when others are experiencing it?

DEFINITIONS OF PAIN

According to Margo McCaffery (1968), a well-known consultant in the care of patients with pain, “Pain is whatever the experiencing person says it is, existing whenever the experiencing person says it does.” This is a reminder to nurses to accept the patient’s report of pain. The International Association for the Study of Pain (IASP) describes pain in a bit more detail by noting it as “an unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage” (2011). This definition indicates that pain is complex and is not only physical but has emotional and other components as well.

Why does pain exist? It is a protective mechanism or a warning. In the presence of injury, pain may help to prevent further injury. Consider the patient who has a fracture and holds it still to prevent further damage or a child who touches a hot stove and pulls his or her hand away before a serious burn occurs.

Suffering, or feelings of continuous distress, often accompanies pain. In a study of suffering, Ferrel and Coyle (2008) concluded, “suffering is not synonymous with pain but is closely associated with it. Physical pain is closely related to psychological, social, and spiritual distress. Pain that persists without meaning becomes suffering” (p. 246). Persistent pain can diminish patients’ quality of life. It can make them feel as though their health is getting worse and take away their motivation for self-care. Suffering can often be relieved if patients believe they can achieve comfort. A good assessment and individualized, culturally congruent approaches to care increase the likelihood of comfort.

RISKS OF UNCONTROLLED PAIN

Why is untreated or undertreated pain a bad thing? Complications can occur when pain is experienced. The body produces a stress response to pain that causes harmful substances to be released from injured tissue. Reactions include breakdown of tissue, increased metabolic rate, impaired immune function, and negative emotions. In addition, pain pre vents the patient from participating in self-care activities such as walking, deep breathing, and coughing. Consider the patient who has had chest surgery and then has to cough and deep breathe. It hurts! Pain may make the patient want to avoid coughing, turning, or even moving. Retained pulmonary secretions and pneumonia can develop. If the patient is less active, return of bowel function is delayed, and an ileus (disruption of normal propulsive gastrointestinal [GI] activity) can result. When pain is well controlled, complications can be avoided, and patients are able to do what they need to do to get well and go home from the hospital or continue with recovery activities.

PAIN AND CULTURE

Cultural differences can affect patient responses to pain. People from various cultures have different ways of expressing pain (see “Cultural Considerations”). Some may be dramatic and emotional; others tend to be stoic and quiet. Knowledge of widely accepted information about different ethnic and cultural groups can be useful in understanding a patient’s experience and what care might be considered acceptable pain responses. It is important, however, to assess a patient’s pain care needs individually and pay careful attention to the ethical principles that influence patient care rather than making assumptions based on culture or ethnicity alone.

WHO’S THE BOSS IN PAIN MANAGEMENT?

The patient is at the center of the health team. Providing accurate information and offering relevant choices helps patients to maintain autonomy. Just as risks, benefits, and alternatives to surgery and anesthesia are discussed with the patient, so too should pain management options be discussed in the process of obtaining informed consent. It is important to learn as much as you can about pain and pain management so you can effectively advocate for your patients and help with patient education.

The entire health team is responsible for pain management. All must provide care in the most cost-effective manner possible while continuing to provide the best quality. Effective pain management helps to reduce costs by minimizing the side effects of opioids, preventing complications related to inadequate pain control, and reducing the length of hospital stay or period of recovery.

Various regulatory bodies have also recognized the importance of good pain management and have incorporated a review of organizational pain management practices into accreditation and review processes. These standards support the importance of appropriate and effective management of pain. They address assessment and the safe pharmacological management of pain, as well as patient and family teaching,
The pain experience may differ between and among individuals of differing cultural, ethnic, or religious groups. Remember that people within groups vary, and not all fit the general descriptions provided here (see Chapter 4).

The care of patients with pain is challenging, however, with a systematic and holistic approach to assessment and treatment, good pain management can be achieved. In this chapter, the difficulties of pain assessment and treatment are discussed. Some of the tools needed to effectively deal with these challenges are presented. Common myths and barriers that continue to affect nursing practice are clarified.

**MYTHS AND BARRIERS TO EFFECTIVE PAIN MANAGEMENT**

A number of factors, including the nurse’s personal experiences with pain, influence how patients with pain are treated. Why are some patients not believed when they report pain? Why do some nurses and other health care team members insist that patients behave a certain way before they are believed? Common myths about pain can impair the nurse’s ability to be objective about pain and may create barriers to effective treatment. Because there are few objective measures for pain, many nurses rely on assumptions rather than facts. Note the following myths.

**Myth:** A person who is laughing and talking is not in pain.

**Fact:** A person in pain is likely to use laughing and talking as a form of distraction. This can be effective in managing pain, especially when used with appropriate drug therapies. Patients may be more easily distracted when they have visitors and may ask for pain medication as soon as their family or significant other goes home.

**Myth:** Respiratory depression is common in patients receiving opioid pain medications.

**Fact:** Respiratory depression is uncommon in patients receiving opioid pain medications. If patients are monitored carefully when they are at risk, such as with the first dose of an opioid or when a dose is increased, respiratory depression is preventable. A patient’s respiratory status and level of sedation (LOS) should be routinely monitored using an LOS scale.

**Myth:** Pain medication is more effective when given by injection.

**Fact:** Oral administration is the first choice if possible, or whenever the IV route is not an option. The IV route has the most rapid onset of action and is the preferred route for postoperative administration. Intramuscular (IM) injections are not recommended because they are painful, have unreliable absorption from the muscle, and have a lag time to peak effect and rapid falloff compared with oral administration.

**Myth:** Teenagers are more likely to become addicted than older patients.

**Fact:** Addiction to opioids is uncommon in all age groups when taken for pain by patients without a prior drug abuse history.

**Myth:** Pain is a normal part of aging.

**Fact:** Although many older adults have medical conditions that cause pain, pain is not a normal or anticipated part of aging and should be treated proactively. Effective pain treatment for older people helps them to maintain their mobility longer and improve overall health.

**OPIOID ADDICTION**

Nurses often express concern about patients who need large amounts of pain medication or know exactly when their next dose of pain medication is due. Nurses may worry that such patients are addicted or that they are “clock watchers,” but do we really know what that means? Patients are expected to be informed about their medications and involved in their care, but when they know when their medications are due, we may become suspicious. In truth, if a patient is watching the clock, the most likely reason is because he or she is in pain. The most common reason that patients ask for more pain medicine is because they have increased pain. Similarly, patients are expected to know the effects of other medications they take, such as blood pressure medications and insulin. Yet when they ask for a specific analgesic, concern that the patient is “drug seeking” is sometimes raised.

**CRITICAL THINKING**

**Mrs. Smithers and Mr. Brown**

- Mrs. Smithers had an abdominal hysterectomy and is sitting up in bed the morning after surgery, putting on her makeup. On morning rounds she is smiling but reports that her pain is at 6 on a scale of 0 to 10. Mr. Brown has just been transferred from the surgical intensive care unit the day after surgery for multiple injuries. He is moaning and reports his pain at 6 on a scale of 0 to 10. Which of these patients is really having as much pain as they say they are? How can you make this judgment?

*Suggested answers are at the end of the chapter.*
It is important to understand the differences among **addiction**, **tolerance**, and **physical dependence**. When talking with patients and teaching them about their medications, it is important to help them understand these differences as well. Addiction is something many patients fear.

**Tolerance** is a normal biological adaptation. Exposure to a drug induces changes that result in a decrease of one or more of the drug’s effects over time. Simply put, this means it takes a larger dose to provide the same level of pain relief. **Physical dependence** is a normal physiological phenomenon that most people experience after a few weeks of continuous opioid use. If an opioid is discontinued abruptly after a few weeks of use or if an opioid antagonist such as naloxone (Narcan) is administered, the patient experiences a withdrawal syndrome that includes such symptoms as sweating, tearing, runny nose, restlessness, irritability, tremors, dilated pupils, sleeplessness, nausea, vomiting, and diarrhea. These symptoms can be prevented by weaning a patient slowly from an opioid rather than stopping it suddenly.

According to the American Society of Addiction Medicine (2011), addiction or **psychological dependence** is a disease of the brain that causes the compulsive pursuance of a substance, or behavior to obtain reward or relief. Addictive behaviors are characterized by impaired control over drug use and continued use despite harm. Patients with uncontrolled pain who desire treatment are not addicts. Sadly, patients with a history of addiction are more likely to have unmet pain needs due to medication tolerance and health provider bias. Careful assessment and monitoring of treatment is essential for all patients receiving treatment for pain—particularly patients who are prescribed opioid analgesics.

**Pseudoaddiction** has been described in patients who are receiving opioid doses that are too low or spaced too far apart to relieve their pain, and certain behavioral characteristics resembling psychological dependence, such as drug-seeking behaviors, have developed. In contrast to the addicted patient, a patient with pseudoaddiction stops drug-seeking behaviors when the pain is relieved.

### CRITICAL THINKING

#### Janet

- Janet is hospitalized with pancreatitis and has severe abdominal pain. She has a history of IV drug abuse. She is receiving IV morphine every 3 hours. Two hours after her last dose, she puts on her call light and says she is in severe pain, which she rates as “15” on a 0 to 10 scale. You feel like you have given her enough morphine to kill a horse, yet she keeps requesting more.

1. How is it possible for Janet to be in pain when she is receiving so much morphine?
2. It’s not time for more medication. What should you do?
Pain Transmission: Nociceptive or Neuropathic?

Pain transmission can be nociceptive and neuropathic. Nociception refers to the body’s normal reaction to noxious stimuli, such as tissue damage, with the release of pain-producing substances. Nociceptive pain may be somatic or visceral. Somatic pain is localized in the muscles or bones. Patients can often point to the exact location of pain and describe it as throbbing or aching. Cancer patients may experience somatic pain when the cancer has spread to the bone or a tumor has invaded soft tissue. Visceral pain, or organ pain, is not well localized and is often described as cramping or pressure. Bowel obstructions and tumors in the lung can cause visceral pain symptoms. Pain may also be felt in parts of the body away from the pain source, such as the low back/flank pain that often accompanies a bladder infection. This is called referred pain (Fig. 10.1).

Neuropathic pain is pain associated with injury to either the peripheral or central nervous system. Unlike nociceptive pain, neuropathic pain is poorly localized and may involve other areas along the nerve pathway. Neuropathic pain is common in cancer patients following chemotherapy or radiation therapy, patients with diabetic neuropathy, and patients who have had shingles. The pain is often described as numbness, tingling, sharp, shooting, or shocklike.

**TYPES OF PAIN**

Acute Pain

Pain is also categorized according to the length of time it has been present. Acute pain is immediate and follows injury to the body, prompts an inflammatory response, and subsides as healing takes place. It is often associated with short-term, objective, physical signs, such as increased heart rate and elevated blood pressure. As pain continues, the physiological responses that accompany acute pain cannot be sustained without harm to the body. As the body adapts, vital signs return to normal. The nurse must guard against labeling such a patient a *malingering* (pretending to be in pain) or drug seeker simply because vital signs are no longer altered. Examples of acute pain include pain related to childbirth, surgery, burns, or other trauma. Persistent acute pain may become chronic.

Chronic Pain

Chronic pain typically lasts 3 months or longer, persisting beyond the time when healing usually takes place. Examples are neck pain that continues years after an accident, pain that accompanies diseases such as arthritis, and phantom limb pain. Patients with chronic pain may have both nociceptive and neuropathic components that require a combination of medications and nonpharmacological treatments. Because of the body’s ability to adapt, patients with chronic pain may not appear to be in pain.

**OPTIONS FOR TREATMENT OF PAIN**

There are many pharmacological and nonpharmacological treatments available for the effective management of pain. Medications that relieve pain are called *analgesics*. Analgesics make up the largest piece of the pain management puzzle and encompass three main classes of medication: opioids, nonopioids, and adjuvants. Opioids bind to opioid receptors in the brain, spinal cord, and other areas of the body, inhibiting the perception of pain. Nonopioids include nonsteroidal anti-inflammatory drugs (NSAIDs) and acetaminophen (e.g., Tylenol). Adjuvants are different from opioid and nonopioids in that they include categories of medications that were originally approved by the Federal Drug Administration for purposes other than pain relief (such as depression). Some patients may require a combination of opioids, adjuvants, and NSAIDs to effectively manage their pain. Nurses should have

---

**FIGURE 10.1** Sites of referred pain.
a good understanding of these pharmacological treatment options. Let’s begin the discussion with nonopioids.

**Nonopiod Analgesics**

Nonopioids are typically the first class of drugs used to treat mild pain (Table 10.1). They can be useful for acute and chronic pain from a variety of causes, such as surgery, trauma, arthritis, and cancer. These drugs are limited in their use because they have a ceiling effect to analgesia. A ceiling effect means that there is a dose beyond which there is no improvement in the analgesic effect, but there may be an increase in adverse effects. When used with opioids, care must be taken to ensure that the nonopioid dose does not exceed the maximum safe dose for a 24-hour period. For example, if a patient receiving two Vicodin (acetaminophen and hydrocodone) tablets every 4 hours continues to experience pain, the dose cannot be increased because of the potentially toxic effects of acetaminophen at that dosage. (See Table 10.1 for side effects and nursing implications.) Nonopioids do not produce tolerance or physical dependence. Most do have antipyretic (fever-reducing) effects.

Nonopioids work mainly peripherally, at the site of injury, rather than in the central nervous system, as opioids do. The exception in this class is acetaminophen, which is believed to act on the central nervous system. NSAIDs block the synthesis of prostaglandins, one of many chemicals needed for pain transmission. In general, it is helpful to include a nonopioid agent in any analgesic regimen, even if the pain is severe enough to require the addition of an opioid (see the section later in this chapter titled “Balanced Approach to Analgesia”).

**Opioid Analgesics**

Opioids are drugs that have actions similar to those of morphine. Opioids are classified by how they affect receptors in the nervous system. They may be full agonists (stimulators), partial

* Tylenol #2 = Tylenol 300 mg + codeine 15 mg; Tylenol #3 = Tylenol 300 mg + codeine 30 mg; Tylenol #4 = Tylenol 300 mg + codeine 60 mg
Opioids alone have no ceiling effect to analgesia. This means that doses can safely be increased to treat worsening pain if the patient’s respiratory status and level of sedation are stable. However, inappropriate prescribing can lead to hyperalgesia, or increased sensitivity to pain. Patients with hyperalgesia have pain at the slightest touch, such as the moving of sheets, and require further medical intervention. Institutions must have policies and procedures in place related to opioids to prevent medication errors and reduce the risk of serious side effects. It is especially important to be vigilant for side effects in patients unaccustomed to opioids. Such patients are sometimes called “opioid-naïve.”

Opioids are added to nonopioids for pain that cannot be managed effectively by nonopioids alone. The use of a centrally acting opioid with a peripherally acting non-opioid can increase pain relief and reduce the amount of opioid needed.

Controlled-release opioids such as oxycodone (OxyContin) and morphine (MS Contin) are effective for prolonged, continuous pain. Whenever a controlled-release form of medication is used, it is important to have an immediate-release medication available for breakthrough pain (transient pain that arises during generally effective pain control), such as oral morphine solution, oxycodone immediate-release (OxyIR), or hydromorphone immediate-release (Dilaudid).

**CRITICAL THINKING**

Mrs. Zales

Mrs. Zales, a 32-year-old woman, was admitted for a hysterectomy after being treated for painful endometriosis for 12 months. After her surgery, she had a patient-controlled analgesia (PCA) pump with hydromorphone, which was effective in relieving her pain. Forty-eight hours after surgery, the surgeon discontinued the PCA pump and ordered oral hydrocodone with acetaminophen. It was ineffective, so an order was added for hydromorphone 2 mg orally every 3 to 4 hours, as needed. The nurses gave only one dose of the hydromorphone. Then, thinking that her pain should be lessening, switched Mrs. Zales back to the hydrocodone with acetaminophen. By the next morning she was in severe pain, and the on-call physician ordered IM meperidine and promethazine (Phenergan). Mrs. Zales’s discharge was delayed until her pain could be controlled.

1. What do you think happened?
2. How could the delayed discharge have been avoided?
3. Who were the important team members in this scenario?

**Suggested answers are at the end of the chapter.**

---

**WORD BUILDING**

- **antagonist**: ant—against + agonist—stimulates receptor site
- **equianalgesic**: equi—equal + analgesic—relieving pain
Meperidine (Demerol) was at one time a commonly used opioid, but is no longer recommended in most cases. Meperidine is an opioid agonist, and when broken down in the body, it produces a toxic metabolite called normeperidine. Normeperidine is a cerebral irritant that can cause adverse effects ranging from dysphoria and irritable mood to seizures. Normeperidine has a long half-life even in healthy patients, so those with impaired renal function are at increased risk. Meperidine use should be avoided in patients over age 65, patients with impaired renal function, and patients taking a monoamine oxidase inhibitor (MAOI) antidepressant. In general, the use of meperidine should be limited to young, healthy patients who need an opioid for a short period and to those who have unusual reactions or allergic responses to other opioids. The effective dose of oral meperidine is three to four times the parenteral dose and is never recommended.

Fentanyl (Sublimaze, Duragesic) can be given parenterally, intraspinally, or by transdermal patch (Duragesic). Fentanyl is commonly used IV with anesthesia for surgery. It is also used to relieve postoperative pain via the IV route, PCA pump, or epidural route (discussed later in this chapter). IV fentanyl has a short duration of action and must be given more often than other opioids. The effective dose of oral meperidine is three to four times the parenteral dose and is never recommended.

Methadone (Dolophine) is a potent analgesic that has a longer duration of action than morphine. It has a long half-life and accumulates in the body with continued dosing. Dosing intervals may be extended after pain relief has been achieved. Methadone is well absorbed from the GI tract and is effective when given orally at doses similar to the parenteral dose.

Methadone is also used in drug treatment programs during detoxification from heroin and other opioids. Patients on methadone maintenance can present a unique challenge when admitted to the hospital. It is important to continue the maintenance dose even if additional pain medications are required after surgery or trauma. See Table 10.1 for examples of opioids.

Opioid Antagonists

Naloxone (Narcan) is a pure opioid antagonist that counteracts, or antagonizes, the effect of opioids. It is often used in emergency departments for treating the effects of opioid overdose, such as sedation and respiratory depression. Caution must be used when giving naloxone to a patient who is receiving opioids for pain control. If too much naloxone is given too fast, it can reverse not only the unwanted effects—such as respiratory depression and sedation—but the desired effect of analgesia as well.

Some antagonists are shorter acting than the opioid that is being used. If the antagonist is given because of respiratory depression, the dose may need to be repeated because its effect may wear off before the opioid wears off.

Some analgesics are classified as combined agonists and antagonists or partial agonists. These drugs bind with some opioid receptors and block others. The most commonly used drugs in this class are butorphanol (Stadol) and nalbuphine (Nubain).

How does this information translate into nursing practice? Consider, for example, a patient who receives sustained-release morphine every 12 hours to control metastatic bone pain, but the patient develops breakthrough pain between doses. You observe that butorphanol has been ordered for pain by another doctor and administer it. The butorphanol will antagonize, or counteract, some of the effects of the morphine, and the patient may experience acute pain. It is important to be informed about the actions of all drugs that are administered and to be aware of possible drug interactions that may interfere with patient care.

Analgesic Adjuvants

Adjuvants are classes of medications that are given in addition to other medications. Analgesic adjuvants can potentiate
the effects of opioids or nonopioids, have analgesic activity themselves, or counteract the unwanted effects of other analgesics. They may be called off-label medications because they are being used in a way not specifically approved by the Food and Drug Administration; that is, they were not initially developed to treat pain. Adjuvants may have pain-relieving properties for certain conditions. Although the use of adjuvants is common, nurses must be mindful of the side effects of these medications, which often affect the central nervous system. Examples of adjuvants are corticosteroids, benzodiazepines, antidepressants, and anticonvulsants.

Corticosteroids can be used to treat a variety of painful conditions, including acute and chronic cancer-related pain. They may be used as part of actual cancer treatment because of their toxicity to some cancer cells, or they may reduce pain by decreasing inflammation and the resulting compression of healthy tissues.

Benzodiazepines such as midazolam (Versed) or diazepam (Valium) are effective for treating anxiety or muscle spasms associated with pain. These drugs do not provide pain relief alone but are effective in treating pain caused by muscle spasms. Benzodiazepines can cause sedation, which limits the amount of opioid that can be safely given at the same time.

Tricyclic antidepressants such as amitriptyline, imipramine, desipramine, and doxepin can help relieve neuropathic pain. Duloxetine (Cymbalta) is a serotonin-norepinephrine reuptake inhibitor that is also effective for nerve pain. These drugs must be taken for days to weeks before they are fully effective, and patients must be told to continue the medication even if it seems ineffective at first. Additional benefits of this class of medications may include mood elevation and improved ability to sleep, but significant side effects often limit their use.

Anticonvulsants such as carbamazepine (Tygvetol) and gabapentin (Neurontin) are often used to relieve neuropathic pain. Again, these medications must be taken regularly to realize their full benefit.

Stimulants such as methylphenidate hydrochloride (Ritalin) or caffeine-containing medications may be used to counteract the sedating effects of opioids in some patients.

**Balanced Approach to Analgesia**

A balanced analgesia approach should be used, combining analgesics and adjuvants from different classes to minimize the adverse effects of opioids, such as nausea and vomiting or sedation, while maximizing pain relief. For example, an opioid and a nonopioid given together can provide pain relief with an overall lower dose of each medication than if each was given alone. Because these drugs have different mechanisms of action and different adverse effects, it is possible to safely use them together. If doses can be reduced in this manner, additional sedating medications such as antiemetics and antihistamines (to treat side effects) may not be needed.

**Scheduling Options**

Analgesics of any kind can be administered either as needed (prn) or on a scheduled basis. Intermittent, unpredictable pain may be best treated with as needed doses. Pain that is predictable can be more effectively treated, or prevented, with scheduled doses of medication. Around-the-clock (ATC) dosing is an effective way to schedule doses evenly over a 24-hour period to prevent pain from becoming unbearable. It is important to use ATC dosing after surgery or trauma, with chronic pain, or in any other circumstance in which pre venting pain will allow the patient to participate in daily or other recovery activities.

**Patient-Controlled Analgesia**

**Patient-controlled analgesia** (PCA) involves an opioid on an IV controller. The patient has a button on a cord that can be pushed to activate a dose of IV medication. The registered nurse (RN) programs the pump to the dose and dosing interval ordered by the HCP. A “lockout” mechanism prevents the patient from receiving the medication more often than ordered. PCA is an excellent option after surgery because it gives the patient some control over pain management. Teach the patient and family that only the patient should push the button, never the nurse or a family member. If the patient is too sedated to push the button, a dose of opioid is not likely needed and could even be dangerous.

**World Health Organization Analgesic Ladder**

In 1990, the World Health Organization (WHO) developed the WHO analgesic ladder to help clinicians to select appropriate medications for pain management based on pain intensity (Fig. 10.2). Although many organizations today use algorithms or flowcharts to help clinicians make appropriate medication choices, the WHO analgesic ladder remains a classic reference.

![Diagram of the World Health Organization three-step analgesic ladder.](image-url)
At the first level, nonopioid analgesics are recommended for mild pain (a verbal rating of 1–3). Typically, at this intensity, patients can perform usual daily activities. When pain is unrelieved by maximum ATC dosing, the treatment moves up the ladder to Level 2, moderate pain, and adds a low dose of an opioid analgesic. A patient with moderate pain (a verbal rating of 4–6) may have trouble working and staying focused. She or he may also begin to have difficulty with usual care activities such as walking, bathing, and dressing. If pain severity increases to severe pain (a verbal rating greater than 6), stronger opioids may be needed. Moderate to severe pain affects the quality of the patient’s life. Addition of adjuvant agents should be considered at all levels.

Best practice mandates the scheduling of pain medica-
tions ATC to prevent breakthrough pain, especially for pa-
tients with cancer and chronic pain. For patients with
surgical or traumatic pain, analgesics should be given ATC
until the pain decreases to a level that allows medications to
be given less often (e.g., as needed, such as before physical
therapy). When using the WHO ladder, it is important to
keep in mind that it is not necessary to start at Level 1 if the
patient is having severe pain. Analgesics from Level 3 on the
WHO ladder may be the starting point for some patients.

**Other Interventions**

Other pain treatments include radiation therapy or antineo-
plastic chemotherapy to help shrink tumors that are causing
pain for a patient with cancer. Chemotherapy is also used for
treating pain associated with connective tissue disorders such
as rheumatoid arthritis and systemic lupus erythematosus
(SLA). Topical local anesthetics such as lidocaine/prilocaine
cream (EMLA) decrease the pain of procedures such as
venipuncture and lumbar puncture. A lidocaine patch may be
effective for patients with postherpetic or other nerve pain.
In patients with osteoporosis, drugs that promote calcium
uptake by the bones can aid in pain relief. These may include
hormonal agents and medications that decrease calcium re-
absorption from bone.

**Placebos**

Use of placebos involves the administration of an inactive substitute such as normal saline in place of an active medication. In the past, placebos were sometimes given in an attempt to determine whether a patient’s pain was “real.” This is unethical and inappropriate unless the patient has given written consent. The use of placebos is a denial of the patient’s report of pain. If a placebo is ordered for a patient, discuss concerns with the physician and nurse supervisor. Placebos are only to be used in drug studies (clinical trials) to compare a new drug with an inactive substance. In this situation, patients are informed that they may be receiving a placebo.

**Routes for Medication Administration**

Analgesics can be administered by almost any route. The oral route is desired in most instances because it is easy and pain-
less for the patient and can be used at home. See Table 10.3
for a comparison of the various routes.

**Nonpharmacological Therapies**

Nonpharmacological treatments are usually classified as either cognitive-behavioral interventions or physical agents. The goals of these two groups of treatments differ. Cognitive-behavioral interventions can help patients understand and

---

**Ms. Jackson**

Ms. Jackson had abdominal surgery 2 days ago. She
has been receiving morphine via IV PCA at an average
of 2.5 mg per hour for the past 6 hours. She rates her
pain at 3 on a scale of 0 to 10. She is to be dischar
ged today. Her physician has ordered codeine 30 mg with
acetaminophen (Tylenol with codeine No. 3), one or two
tablets every 4 hours as needed for pain at home.

Will Ms. Jackson be comfortable at home? Why or
why not?

*Suggested answers are at the end of the chapter.*

</table>
cope with pain and take an active part in its assessment and control. The goals of physical agents may include providing comfort, correcting physical dysfunction, or altering physiological responses. Nonpharmacological therapies should be used in conjunction with drug therapies and are not expected to relieve pain on their own.

**Cognitive-Behavioral Interventions**

Included in this group are interventions such as educational information, relaxation exercises, guided imagery, distraction (e.g., music, television), and biofeedback. These treatments require extra time for detailed instruction and demonstration. The use of these modalities must be acceptable to the patient to be useful. Educating patients about what to expect and how they can participate in their own care has been shown to decrease patients' reports of postoperative pain and analgesic use.

Relaxation can be accomplished through a variety of methods. The patient may prefer a scripted relaxation exercise that can be practiced and used the same way each time or simply the use of a favorite piece of music that allows a state of muscle relaxation and freedom from anxiety. Guided imagery uses the patient's imagination to take the patient away from the pain to a favorite place, such as a beach in Tahiti. The success of guided imagery does not mean that the pain is in any way imaginary. See Chapter 5 for more information on relaxation and imagery.

As noted earlier, distraction is commonly used by patients to focus their attention on something other than the pain. They may watch a favorite television program or laugh with visitors when they are in pain. When the program is over or the visitors leave, the patient may focus on the pain again and ask for a dose of pain medication.

Biofeedback is sometimes used in chronic-pain programs to teach patients how to train their bodies to respond to different signals. Biofeedback has been very useful in patients with migraine headaches. When an aura (a warning sign) occurs before a migraine headache, patients are prompted to begin the exercise that relaxes them and may allow them to prevent the headache.

**Physical Agents**

Physical agents can contribute directly to the patient’s comfort. Examples of physical agents include applications of heat or cold, massage, and exercise, discussed next. Additional physical interventions such as immobilization or TENS are also available.

**APPLICATION OF HEAT.** The application of heat to sore muscles and joints is effective for pain relief. Heat works to increase circulation, induce muscle relaxation, and decrease inflammation when applied to a painful area. Heat can be applied using dry or moist packs or wraps, or in a bath or whirlpool. Heat is contraindicated in conditions that would be worsened by its use, such as in an area of trauma, because of the possibility of increased swelling caused by vasodilation. To prevent burns, heat should not be applied directly to skin or over areas of decreased sensation.

**APPLICATION OF COLD.** Cold can reduce swelling, bleeding, and pain when used to treat a new injury. Cold can be applied by a variety of methods, such as cold wraps and cold packs, as well as localized ice massage. Patients often choose heat over cold if they have the choice, because cold can be uncomfortable. Cold may be better tolerated over a small area. Alternating heat and cold therapies is most effective if not contraindicated.

**MASSAGE AND EXERCISE.** Massage and exercise are used to stretch and regain muscle and tendon length and to relax muscles. Massage pressure can be superficial or deep. It is important that massage is acceptable and not offensive to the patient. Immobilization is used after a variety of orthopedic procedures, as well as fractures and other injuries worsened by movement. Acupressure has also been shown to be beneficial for pain reduction (See “Evidence-Based Practice”).

Physical agents are readily available, inexpensive, and require little preparation or instruction. But always remember, it is important to use nonpharmacological treatments to enhance appropriate drug treatments, not as a substitute.

---

**EVIDENCE-BASED PRACTICE**

Clinical Question
Can acupressure help relieve pain and reduce the need for pharmacological analgesics?

Evidence
Fifteen small studies were reviewed to determine the effectiveness of using finger and hand pressure to stimulate acupuncture points and relieve pain. The studies demonstrated a reduction in menstrual, labor, low back, headache, and other types of pain in diverse populations.

Implications for Nursing Practice
“Acupressure can be efficiently conducted by health care professionals as an adjuvant therapy in general practice for pain relief” (Chen & Wang, in press).

REFERENCE
**Patient Perspective**

**Terry Versus Joanne**

I (Terry) have had chronic back pain for 10 years. It is very real, related to multiple herniated discs in my thoracic and lumbar spine, arthritis, and degenerative disc disease. Because I’ve been dealing with it for 10 years, I have adapted—I never look like I am in pain. Sometimes I limp or move around a lot to find a comfortable position, but I don’t have that pained look on my face, and my blood pressure doesn’t go up like some people. I have tried many, many medications over the years and have become quite educated in pain treatments. I have tried antidepressants and antiseizure medications (both are used for neuropathic pain), ice, heat, TENS, relaxation, physical therapy, more physical therapy, exercises, more exercises, massage therapy, steroid injections, and nerve blocks. I had relief once for about a month following some injections, and I kept thinking something was wrong. “Wait, where’s the pain? This doesn’t feel right!” Sometimes I would like a big dose of morphine, but I know that opioids for chronic pain are a one-way street to dependence. I do have a prescription for hydrocodone and acetaminophen (Vicodin) that I take a couple of times a month when I feel desperate. I ration them because I am afraid of them.

My friend Joanne also has back pain, which started 20 years ago. When it started, she was writhing in pain—I am positive her blood pressure was sky high! She couldn’t move because of muscle spasms. She was also diagnosed with a herniated disc, but she was able to have surgery to fix it. She said the nerve pain relief was already evident in the recovery room. Of course, surgery causes pain, so opioids are needed for a short while. But once healing started for Joanne, no pain! She still has acute pain from time to time, when she experiences muscle spasms and can’t move very easily for several days. She takes muscle relaxers and has to lay low until the spasms resolve.

Sometimes Joanne looks at me and says, “You don’t look like you’re in pain.” At first this made me feel bad, like she was comparing her pain to mine. Then one day, I realized the difference—she experiences acute pain, and I have chronic pain. I’ve adapted. She is way more miserable than I am when she is in pain, but it is short-lived. My pain is not as severe, but after 10 years, it has worn me down.

When you are a nurse, please believe your patients when they say they are in pain, even if they don’t look like they are. Maybe they’ve gotten used to it, but that doesn’t mean they enjoy feeling pain. Do whatever you can to help them feel better.

---

**Chapter 10**

**Nursing Care of Patients in Pain**

in condition, and at least quarterly thereafter while in care. Nurses should verbally assess all patients under their care at least once per shift for pain and provide appropriate intervention as needed. The **WHAT’S UP?** format, introduced in Chapter 1, can help you perform a complete and effective assessment (Table 10.4). The following sections provide some additional key points for assessing pain and putting together more pieces of the pain puzzle.

**Accept the Patient’s Report of Pain**

Pain is what the patient says it is, not what the HCP believes it is. When a member of the health care team distrusts the patient’s report of pain, the patient can usually sense this. The patient may compensate by either underreporting pain or, less commonly, anxiously overreporting. Patients may try to hide their pain for fear of being thought of as complainers or drug seekers.

**Obtain a Pain History**

Obtain information from the patient about the pain he or she is experiencing. Letting the patient describe the pain in his or her own words helps establish a trust relationship between you and the patient. This is also the time to discover the effects the pain is having on the patient’s quality of life. Does the pain prevent the patient from eating, sleeping, or participating in work or family activities? Are there adverse effects such as nausea and vomiting or constipation that need to be addressed? Also assess emotional and spiritual distress and coping abilities. Ask the patient about how he or she has coped with pain previously and what treatments he or she prefers. Information may be obtained from family members and the medical record. A painful diagnosis, such as arthritis, typically is a predictor of pain. A thorough history is essential so you can individualize pain interventions to fit the patient’s needs.

**PAIN ASSESSMENT TOOLS.** Various tools are available to assist with accurate and complete pain assessment. You should become familiar with the tools used in your clinical practice, setting, and use them consistently. It is of utmost importance that all health care personnel caring for a particular patient use the same pain rating scale, whether it is a numerical scale (e.g., 0–10), a visual analog scale (Fig. 10.3), or the FACES-R scale (FPS-R) (Fig. 10.4). There should also be consistent scales in place for nonverbal/cognitively impaired patients such as the PAINAD (Pain Assessment in Advanced Dementia Scale; Ward, Hurley, & Wolcer, 2003; Fig. 10.5).

Whatever scale is used, it must be one that has been validated with research. The FACES-R scale was initially developed for use in children and has since been revised with faces that are more realistic for adults. The PAINAD scale was developed for patients with advanced dementia but is an effective tool for patients with cognitive and communicative barriers. Longer questionnaires are useful in meeting regulatory requirements for the completion of comprehensive pain assessments (Fig. 10.6). These scales often contain examples of verbal pain descriptors—something many patients
have difficulty verbalizing. A scale should also be used to monitor the patient’s level of sedation after opioid administration (Fig. 10.7). Any unexpected increase in the patient’s level of sedation should be reported promptly to the RN or HCP. Finally, keeping a pain diary may help patients to document pain ratings, interventions, and responses, which can aid effective intervention.

**Perform a Complete Physical Assessment**

A thorough physical assessment is necessary to determine the effect of the pain and pain treatments on the body. It helps identify all of the pain sites and any medication side effects and helps prioritize the seemingly overwhelming task of helping the patient achieve acceptable pain relief and good quality of life. As discussed previously, the patient with acute pain may exhibit signs such as grimacing and moaning or elevated pulse and blood pressure. For patients with cognitive impairments, these indicators can be particularly important; however, these signs cannot be relied on to “prove” that a patient is in pain.

The only reliable source of pain assessment is the patient’s self-report (“Gerontological Issues”). Even patients with cognitive deficits can provide important information about pain. They can often answer simple yes or no questions regarding comfort and may demonstrate favorable changes in behavior, such as diminished calling out, when pain is effectively controlled.

**FIGURE 10.3** Analog pain scale.

Older adults frequently have unmet pain needs. Many believe that pain is an anticipated part of aging and may be hesitant to take strong medications such as opioids for pain. NSAIDs are often contraindicated for older adults due to medication interactions and GI side effects; however, patients should be evaluated for medications on an individual basis. Patients in long-term care facilities, particularly patients with cognitive deficits, should have medications for pain scheduled ATC to ensure regular administration and effective pain control. Consider incidence of isolation, restlessness, confusion, aggression, and changes in appetite as possible signs of pain. Pulling at dressings, tugging at IV sites, and calling out can also be symptoms of discomfort. Any change in the patient’s usual behavior should be considered a possible sign of discomfort. Remember to take more time when assessing pain in older patients because they may need more time to process what you are asking. Consider using the PAINAD Scale when assessing confused patients.

You can anticipate pain and provide relief measures to prevent severe pain. A trial dose of pain medication may help to determine if the patient’s behavior is because of pain. Nagging achiness in hands and feet is often noted as a reason for decreased activity, inability to sleep, and altered functional ability. A hand or foot massage using lotion and gentle massage strokes is often a relaxing comfort measure.

Opioid analgesic doses may need to be decreased by 25% to 50% initially because the y tend to work longer and stronger in the older patient.

Nursing Diagnoses, Planning, and Implementation

See the “Nursing Care Plan for the Patient in Pain.” Some additional principles to consider during planning and implementation follow.

Set Goals With Patients and Caregivers

Establish a pain control goal during the planning phase. Ask the patient to determine an acceptable level of pain if complete freedom from pain is not possible. Patients with cognitive deficits should also have pain goals established that include behavioral indicators. Education is important when helping patients and caregivers set realistic pain control goals. Although a goal of 0 pain is desirable, it may not be possible or safe. On the other hand, a patient who chooses a pain goal of 6 may be unable to get out of bed and do other recovery or daily activities. Patients should also identify activity goals. After surgery, goals may include the ability to ambulate and achieve restful sleep. For patients with chronic pain, the goals may be different. For example, a patient with terminal cancer may want to be able to eat dinner with her family in the evening. You can assist the patient in reaching that goal by teaching her to conserve energy during the day for the activity that is most important to her. Instructing both patients in optimal timing of pain medications will also assist them in reaching their desired activity goals.

Giving patients pain management options can provide autonomy and may help prevent feelings of helplessness and hopelessness. It is the nurse’s responsibility to engage the patient and family in the pain management plan.

Understand That Pain Affects the Whole Family
It is important to include the whole family in the pain management plan. Understanding family dynamics helps the nurse in implementing an effective plan. Cultural influences are also important to consider (see Chapter 4 and “Cultural

NURSING CARE PLAN for the Patient in Pain

Nursing Diagnosis: Pain (acute or chronic)

Expected Outcomes: Pain will be at a level that is acceptable to the patient. Patient will be able to participate in activities that are important to him or her.

Evaluation of Outcomes: Is pain at a level that is acceptable to the patient? Is the patient able to participate in activities that he or she has identified as important?

Intervention Assess pain based on patient report. Use the WHAT’S UP? format. Rationale Patient’s pain is defined as what the patient says it is, when the patient says it is occurring. Evaluation Does the patient verbalize his or her pain? Does the patient use verbal or nonverbal messages that imply trust in nurse’s belief of pain report?

Intervention Teach the patient to use a pain rating scale. Use the same scales consistently. Rationale A rating scale is the most reliable method for assessing pain severity. Evaluation Does the patient understand the use of the scale and use it to report pain?

Intervention Have the patient or caregiver keep a pain diary, documenting time of pain, interventions, and pre- and postpain ratings. Rationale A diary can show patterns of pain and pain relief, and help in planning care. Evaluation Does the diary reveal patterns that help with planning?

Intervention Determine what is an acceptable pain level for the patient. Consider activities the patient should be able to perform. Rationale Only the patient can decide what pain level is acceptable. Evaluation Is the patient’s pain at an acceptable level? Can they perform necessary activities of daily living (ADLs) with minimal pain?

Intervention Assess whether pain is nociceptive, neuropathic, or both. Rationale Nociceptive and neuropathic may present differently and may require different interventions. Evaluation Has nociceptive versus neuropathic pain been identified? Are treatments appropriate?

Intervention Assess need for and offer emotional, spiritual, and social support for the experience of pain and suffering. Rationale Pain, as well as disease processes, can be accompanied by feelings of powerlessness, distress, and isolation. Evaluation Does the patient appear emotional, angry, or withdrawn? Does the patient have difficulty making decisions? Does the patient have a support system? Is the patient-nurse relationship therapeutic?

Intervention Give analgesics before pain becomes severe. For persistent pain, give analgesics around the clock. Rationale Pain can be more difficult to relieve when it becomes severe. Evaluation Is analgesic schedule effective?

Intervention Combine opioid and nonopioid analgesics as ordered. Rationale Balanced analgesia provides optimum pain relief with fewer side effects. Evaluation Is the analgesic combination effective?

Intervention Assess for pain relief approximately 1 hr after administration of oral analgesics, or 30 min after IV analgesics. Rationale If pain is not relieved, additional measures will be needed. Evaluation Does patient report acceptable level of relief?

Intervention Observe for adverse effects of pain medication. Rationale Many pain medications cause nausea and fatigue. Both tend to subside after a few days. Evaluation Are adverse effects occurring? Can they be managed? Does medication regimen need to be adjusted?
Considerations”). It is difficult for family members to see loved ones in pain or in heavily sedated states. Including them in planning helps them feel that they can help make the patient more comfortable and recognizes the important role they have in the patient’s care.

Pain Is Exhausting

Pain may keep the patient from sleeping well. This cycle of sleeplessness and pain must be interrupted to help the patient. Fatigue is a common problem for the patient with chronic pain and can complicate the treatment process. Although older adults do not require as much sleep as younger adults, patients must get at least 6 to 7 hours of uninterrupted sleep to be relaxed enough to break the cycle. Controlled-release opioids may help maintain pain relief throughout the night. If controlled-release medications are not used, it may be necessary to wake a patient to administer pain medication so that the pain does not get out of control. The addition of a sedative or sleep aid may be needed to allow the patient to sleep. Aromatherapy such as lavender, ensuring patient is comfortable, and limiting caffeine intake after 1500 can increase productive sleep.

A Team Approach to Pain Management

The interdisciplinary pain management team includes the patient and family, the nurse, the physician or HCP, therapists, spiritual advisers, social workers, and pharmacists. Communication among team members is essential. It is the important link that allows the team to be effective in creating a plan that works for the patient. As the nurse, you play a vital role in ensuring effective communication among team members, always remembering that the patient is at the center of the team.

Patient Education

Patients, and in some instances their family members, must be informed about the medications they are taking for pain management. This allows them to take an active role in their care. Patients who are informed about the goals of pain management and who are confident that their providers believe they are more likely to report unrelieved pain so that the y can receive prompt and effective treatment. Goals include a satisfactory comfort level with minimal side effects and complications of pain and its treatment, as well as a reduced period of recovery.

The patient should be provided with information about a drug’s effects, common adverse effects, frequency of the dose and duration of action, and potential drug-drug and drug-food interactions, if indicated. There are many special considerations for medications, such as controlled-release oral agents and transdermal patches; care must be taken to include these considerations in the education plan for the patient taking these drugs at home. Drug-specific instructions are found in drug handbooks or databases. Education must be presented at a level that the patient can understand. Written information should be included when appropriate. Informed patients use their medications more effectively and safely.
Evaluation

The final phase of the nursing process is evaluation. Once the plan of care has been implemented, evaluate whether the patient’s goals have been met. What is the patient’s pain rating? Has the patient’s identified goal for an acceptable level of pain been met? How were the pain treatments tolerated? Was the patient able to participate in activities that he or she identified as important? The plan should be continuously updated based on the evaluation.

CRITICAL THINKING

Mr. Sebastian

- Mr. Sebastian is a 75-year-old man who has been diagnosed with lung cancer and is anxious about leaving the hospital to return home following surgery. The nursing assessment reveals the need for home health care for dressing changes and teaching about the medications he will need at home. While in the hospital, Mr. Sebastian has required 5 mg of IV morphine every 4 hours around the clock.

1. The morphine is available in syringes pre-filled with morphine grains 1/6 per mL. How many milliliters should the nurse administer while Mr. Sebastian is in the hospital?
2. What discharge instructions must be given to Mr. Sebastian and his wife before sending him home?
3. How might his pain be managed at home to prevent unnecessary readmissions to the hospital?

Home Health Hints

- Emotional or spiritual distress and fear related to dependence on family caregivers may alter the patient’s perception or report of pain. Some patients may feel pain more intensely because of the influence of fear, and others may underreport if they are trying to protect family members.
- Pill boxes are useful to ease in administration of medications and for nurses to track usage.
- Massage is commonly used for the treatment of chronic pain, especially musculoskeletal pain. Remember a physician’s order might be necessary for this type of treatment. Discuss this option with the HCP, patient, and caregiver to help determine if this intervention is appropriate for your patient.

CRITICAL THINKING

Mrs. Smithers and Mr. Brown

- It is important to accept both patients’ pain reports. Assessment should be based on what the patient says rather than what is observed. Each patient copes with his or her pain in a unique way, and the nurse cannot judge whether one is in more pain than the other.

Janet

1. Remember, pain is whatever the experiencing person says it is, existing whenever the experiencing person says it does. You must assume that Janet is in pain. She has pancreatitis, which is commonly very painful. She has a history of IV drug abuse and is likely tolerant to the effects of the morphine. She may be experiencing “end-of-dose failure,” when pain medication does not last as long as expected. If her vital signs are within normal limits, it should be safe to treat her pain.

2. Contact the RN or HCP and explain the problem. Making Janet wait another hour in pain is not appropriate.
3. Tylenol works differently from morphine and may offer minimal relief but is not an appropriate order for severe pain. Talk to the RN or supervisor and explain the situation.
4. Listen to Janet and let her know that you understand she is in pain. Keep her updated at all times and assure her that you will continue to advocate for her until she achieves adequate pain relief.

Mrs. Zales

1. Mrs. Zales may have been tolerant to opioids because of her need for medication for chronic pain during the past year. For this reason, she needed more medication than a nontolerant patient who does not usually use opioids. Also, the belief that promethazine and other phenothiazines potentiate opioids is a myth. They do cause increased levels of sedation and may limit the
amount of opioid that can be given safely. IM injections are not recommended because they are painful, absorption is not predictable, and there is a delay between injection and relief. A more rational approach to Mrs. Zales’s pain management would have been regular pain assessment with ATC treatment until the pain began to subside.

2. If her pain level had been better controlled, she might have been discharged on oral analgesics without the delay.

3. The most important team member here was Mrs. Zales—the patient should be the CENTER of the team! If she had been listened to more carefully and her history considered, she might have been kept more comfortable.

■ Mrs. Shepard

1. Pain medication is most effective when given on a routine schedule around the clock to avoid breakthrough pain. Mrs. Shepard’s epidural infusion should continue to relieve her pain for a time, up to several hours after it is discontinued, depending on the medication used. The oral medication is most effective when given at the time the epidural is stopped so that it is taking effect as the epidural effects wear off. See “Gerontological Issues” for special considerations for the older patient.

2. Pain prevents patients from moving freely. Postoperative complications such as retained pulmonary secretions and ileus can occur when patients are immobile. Effective pain management can help prevent these complications.

3. If she takes a dose every 3 hours, then she will receive eight doses in 24 hours: 500 mg x 8 = 4000 mg or 4 g, which is the maximum safe dose. Recall that older adult patients metabolize and excrete medications more slowly than younger patients. If she will need the hydrocodone/acetaminophen for more than a few days, it would be wise to consult with the physician about giving the opioid and acetaminophen separately.

4. Mrs. Shepard should be instructed about what her role will be when her pain management regimen is altered. Does she have to ask for the pain medication, or will it just be brought to her? Patient and family education are vital to success in management of a patient’s pain.

■ Ms. Jackson

Using an equianalgesic conversion, we can determine whether Ms. Jackson is likely to have good pain relief based on her requirement with the PCA. Her current pain level of 3 shows that the morphine has been effective. Remember that the pump keeps a history of what the patient uses, which is the best indicator of what the patient needs. Ms. Jackson has used 15 mg of morphine during the past 6 hours. An equianalgesic dose of Tylenol with codeine No. 3 would be almost 200 mg of codeine, but only 30 to 60 mg has been ordered. In addition, if Ms. Jackson takes enough Tylenol with codeine No. 3 to get 200 mg of codeine, she will receive a dangerous dose of both the codeine and the acetaminophen. The physician needs to be contacted for different analgesic orders.

■ Mr. Sebastian

1. 5 mg 1 grain 1 mL = 0.5 mL

2. Home instruction regarding ATC administration of pain medication is indicated, as well as effects and side effects to report. He will also need to implement measures to prevent constipation.

3. MS Contin, a long-acting oral form of morphine, may be an option for Mr. Sebastian, along with an immediate-release preparation for breakthrough pain. Make sure to check an equianalgesic chart to be sure his oral dose is adequate. Also, information about what to do and whom to contact if pain becomes unmanageable is necessary to help prevent readmissions to the hospital.
Chapter 10  Nursing Care of Patients in Pain  169

REVIEW QUESTIONS

1. A patient is walking up and down the hall and visiting and laughing with other patients. When the nurse approaches, the patient reports a pain level of 6 on a scale of 0 to 10. Based on McCaffery’s definition of pain, which of the following assumptions by the nurse is most likely correct?
   1. The patient is not really in pain but just wants his medication.
   2. The patient is having pain at a level of 6 on a scale of 0 to 10.
   3. The patient is in minimal pain and should receive an oral analgesic instead of an injection.
   4. The patient is in pain but does not need his pain medication yet.

2. A patient with terminal cancer has been requiring 5 mg of IV morphine every 1 to 2 hours to control pain, yet is engrossed in a movie on television and appears to be in no pain. Which of the following explanations of this behavior is most likely correct?
   1. Denial of pain is common in patients with cancer.
   2. The cancer treatment is working and the pain is improving.
   3. The patient is hiding the pain to finish watching the movie undisturbed.
   4. Distraction can be an effective treatment for pain when used with appropriate drug treatments.

3. What action should the nurse take when a patient who is in pain develops tolerance to opioid analgesics?
   1. Slowly wean the patient from opioids.
   2. Request a referral to an addiction specialist for the patient.
   3. Talk to the RN or HCP about increasing the dose of analgesic.
   4. Offer the patient nonopioid alternatives for pain control.

4. A patient has surgical site pain 24 hours after a total hip replacement. All the following medications are ordered. Which would be the most appropriate choice for the patient at this time?
   1. ibuprofen (Motrin)
   2. hydromorphone (Dilaudid)
   3. acetaminophen (Tylenol)
   4. gabapentin (Neurontin)

5. A patient is receiving duloxetine (Cymbalta) for neuropathic pain related to diabetes. For which symptoms of neuropathic pain should the nurse assess?
   1. Tingling, shocklike pain
   2. Dull aching pain
   3. Deep cramping pain
   4. Throbbing, aching pain

6. Which of the following methods is the most reliable way to assess the severity of a patient’s pain?
   1. Ask the patient to describe the pain.
   2. Observe the patient for physical signs of pain such as moaning or grimacing.
   3. Ask the patient to rate his or her pain using a valid assessment scale.
   4. Ask a family member to rate the patient’s pain.

7. According to the World Health Organization’s analgesic ladder, at what point in a patient’s pain experience is it appropriate to use adjuvant treatments? Select all that apply.
   1. In addition to analgesics for early, mild pain
   2. As an alternative to analgesics for mild to moderate pain
   3. As an alternative to analgesics for severe pain
   4. In addition to analgesics for pain that is persistent despite treatment
   5. In addition to analgesics for pain that is growing increasingly severe

8. A patient is hospitalized following a motor vehicle accident with multiple orthopedic injuries and reports acute pain at an 8 on a 0 to 10 scale. An order is written for morphine 6 mg IV every 4 hours as needed, as well as a nonopioid oral analgesic every 4 hours as needed. To reduce the risk of adverse effects and maintain an acceptable level of sedation and pain control, which of the following analgesic schedules will be most effective?
   1. Offer the opioid every 4 hours.
   2. Tell the patient to call when pain becomes severe, and then give the drugs immediately.
   3. Give both the IV opioid and the PO nonopioid every 4 hours around the clock.
   4. Alternate the IV analgesic with the nonopioid oral analgesic as needed.

9. An 88-year-old patient is admitted with a broken hip after a fall. An order is written for meperidine 50 to 75 mg IM every 4 hours prn (as needed) for pain. Which of the following actions should the nurse take first?
   1. Give the meperidine every 4 hours ATC.
   2. Offer the meperidine every 4 to 6 hours prn.
   3. Administer an NSAID with the meperidine for added pain relief.
   4. Discuss the order with the RN or HCP.
10. A patient is started on gabapentin (Neurontin) 300 mg by mouth three times daily for chronic low back pain related to lumbar disc herniation. Which instruction should the nurse provide?
   1. “Take the medication at the first sign of any pain, up to three times daily.”
   2. “Take one capsule every 8 hours continuously to keep the pain under control.”
   3. “Take the medication only when you need it, to prevent becoming addicted.”
   4. “Take one capsule three times a day, then stop it when the pain is under control.”

11. A nurse receives an order to administer 1 mL of sterile normal saline solution IM to a patient suspected of opioid abuse. Which response by the nurse is appropriate first?
   1. Administer the saline and carefully document the patient’s response in the medical record.
   2. Administer the saline but inform the patient exactly what it is and why it was ordered.
   3. Refuse to administer the medication and inform the physician that the order is inappropriate.
   4. Share concerns about the order with the supervisor and explain why the nurse cannot in good conscience administer the saline.

12. A nurse needs to administer morphine 10 mg IM. It is supplied as grains 1/4 per mL. How many milliliters should the nurse prepare for injection?
   Answer: ________ mL

Answers can be found in Appendix C.

Nursing Care of Patients With Cancer

LUCY L. COLO AND JANICE L. BRADFORD

LEARNING OUTCOMES

1. Explain the normal structures and functions of the cell.
2. Describe changes that occur in a cell when it becomes malignant.
3. Identify commonly used chemotherapeutic agents.
4. Discuss the special nursing needs of the patient receiving chemotherapy or radiation therapy.
5. Identify data to collect when caring for a patient with cancer.
6. Recognize common oncological emergencies and related nursing care.
7. Discuss how you will know if your nursing interventions have been effective.
8. Describe the role of hospice in providing care for patients with advanced cancer.

KEY TERMS

alopecia (AL-oh-PEE-she-ah)

Cells are the smallest living structural and functional subunits of the body. Although human cells vary in size, shape, and certain metabolic activities, they have many characteristics in common.

**Cell Structure**

Human cells have a plasma membrane, cytoplasm (cytosol, organelles), and a nucleus (Fig. 11.1). Organelles are specific in structure and function. Variations in the relative amounts of organelles and cell features allow great diversity in cells, and therefore in tissues.

**Nucleus**

The nucleus of a cell is its control center, containing the individual’s unique deoxyribonucleic acid (DNA) sequence (Fig. 11.2). Most cells have one central nucleus, although variations exist.

DNA coding regions are called genes; a gene is the code for one protein. Not all of the genes in a particular cell are active, only those needed for the proteins required to carry out their specific functions. These proteins may be structural, such as the collagen of connective tissue, or functional, such as the hemoglobin of red blood cells (RBCs). Important functional proteins are the enzymes that catalyze the specific reactions characteristic of each type of cell.

**Genetic Code and Protein Synthesis**

The genetic code of DNA is the code for the amino acid sequences needed to synthesize a cell’s proteins. The assembly of amino acids into the primary structure of a protein is a two-step process: transcription and translation. Transcription makes a copy of the code needed for a protein so DNA can remain guarded in the nucleus. Translation occurs at the ribosome where the nucleotide code of nucleic acids is translated into the amino acid code of protein (see Fig. 11.3).

As with any complex process, mistakes are possible. If there is a mistake in the DNA code, the process of protein synthesis may continue, but the resulting protein will not function normally; this is the basis for genetic diseases. DNA mistakes acquired during life are called mutations. A mutation is any change in the DNA code. Ultraviolet rays or exposure to certain chemicals may cause structural changes in the DNA code. These changes can kill the affected cells or may irreversibly alter their function. Such altered cells can become malignant, being unable to function normally. These cells actively replicate the mutated DNA during division, creating a mass of faulty cells. This is the basis of some forms
Perforating the nuclear envelope are nuclear pores. These pores regulate the passage of molecules into the nucleus (such as those needed for construction of RNA and DNA), as well as out of the nucleus (such as RNA, which leaves the nucleus to perform its work in the cytoplasm).

Extending throughout the nucleoplasm (the substance filling the nucleus) are thread-like structures composed of DNA and protein called chromatin. When a cell begins to divide, the chromatin coils tightly into short, rod-like structures called chromosomes.

In the center of the nucleus is the nucleolus. The nucleolus manufactures components of ribosomes, the cell’s protein producing structures.

Transcription

1. When the nucleus receives a chemical message to make a new protein, the segment of DNA with the relevant gene unwinds.

2. An RNA enzyme then assembles RNA nucleotides that would be complementary to the exposed bases. The nucleotides attach to the exposed DNA and then bind to each other to form a strand of messenger RNA (mRNA). This strand is an exact copy of the opposite side of the DNA molecule.

Translation

Waiting in the cytoplasm are tRNA molecules. Each tRNA consists of three bases (a triplet called an anticodon) that will perfectly complement a specific site (the codon) on the mRNA. Attached to the tRNA is the amino acid for that site, according to the genetic “blueprint.”

The tRNA finds the three bases that are complementary to its own and deposits the amino acid.

The ribosome then uses enzymes to attach the lengthening chain of amino acids together with peptide bonds.

When each triplet has been filled with the correct amino acid and the peptide bonds have been formed, the protein is complete.

of cancer, which is a general term for many types of malignant growths.

**Mitosis**
Mitosis is cell reproduction. One cell, after its 46 chromosomes have replicated, divides into two cells, each with a complete set of chromosomes. Mitosis is necessary for the growth of the body and the replacement of dead or damaged cells. Not all cells are capable of mitosis; of those that are capable, the rate of division varies widely by tissue type. Some cells are capable of only a limited number of divisions; once that limit has been reached and the cells die, they are not replaced. Shortly after birth, almost all neurons lose their ability to divide, and muscle cells have limited mitotic capability. When such cells are lost through injury or disease, the loss of their functions in the individual is usually permanent.

**Cell Cycle**
The cell cycle involves a series of changes through which a cell progresses, starting from the time it develops until it reproduces itself. The duration of the cell’s life, the time it takes for mitosis to occur, the growth ratio (percentage of cycling cells), the frequency of cell loss, and the doubling time (the time for a tumor—an abnormal mass—to double its size) are important concepts related to tumor growth and treatment strategies.

At any point in time, some cells are actively dividing, others leave the cycle after a certain point and die, and still others temporarily leave the cycle and remain inactive until reentry into the cycle. Inactive cells continue to synthesize (ribonucleic acid [RNA] and protein; Fig. 11.4).

**Cells and Tissues**
A tissue is a group of like cells with the same structure and function. The four categories of human tissues are epithelial, connective, muscle, and nervous. Tissues organize into organs; organs construct systems; and systems form the individual. Because of this hierarchy, if a dividing mass of cells is mutated, the abnormality will produce symptoms at the higher levels.

---

**INTRODUCTION TO CANCER CONCEPTS**

Oncology is the branch of medicine dealing with tumors. Oncology nursing is also called cancer nursing; it is an important component of medical-surgical nursing care. The National Cancer Institute (NCI) reports that an estimated 13.7 million Americans alive today have a history of cancer (American Cancer Society [ACS], 2013a). Early accounts of cancer date back to the 17th century B.C. Documentation of the benefits of early cancer detection and treatment exist from the beginning of the 19th century. Today, microscopic technology and genetic engineering provide health care providers (HCPs) with a better understanding of tumor growth and cell activity and a means for early cancer detection and intervention. Box 11-1 lists some helpful cancer resources.

**Benign Tumors**
Cells that reproduce abnormally result in neoplasms, or tumors. Neoplasm is a term that combines the Greek word *neo*, meaning “new,” and *plasia*, meaning “form,” to suggest new tissue growth. A benign tumor is a cluster of cells that is not normal to the body but is noncancerous. Benign tumors grow more slowly than malignant ones and have cells that are the same as the original tissue. An organ containing a benign tumor usually continues to function normally. A neoplastic growth is difficult to detect until it contains about 500 cells and is about 1 cm in diameter.

**Cancer**
Cancer is a group of cells that grows out of control, taking over the function of the affected organ. Cancer cells are poorly constructed, loosely formed, and disorganized. A simplistic definition is “confused cell.” An organ with a cancerous tumor eventually ceases to function. Malignant, a term
often used to describe cancer, means that the tumor resists treatment and tends to worsen and threaten life. A comparison of benign and malignant tumors is found in Table 11.1.

**Etiology**

Cancer cell growth and reproduction involve a two-step process: initiation and promotion. The first step in cancer growth is called *initiation*. Initiation causes an alteration in the genetic structure of the cell (DNA). Cell alteration is associated with exposure to a *carcinogen*, which is a substance or agent that increases the risk of cancer. The cellular change primes the cell to become cancerous.

*Promotion* is the second step of cancer cell growth. It occurs after repeated exposure to carcinogens causes the initiated cells to mutate. During the promotion step, a tumor forms from mutated cell reproduction.

A healthy immune system can often destroy cancer cells before they replicate and become a tumor. It is important to remember that any substance that weakens or alters the immune system puts the individual at risk for cell mutation. Medical researchers support the theory that cancer is a symptom of a weakened immune system.

**Pathophysiology**

Cancer is not one disease but many diseases with different causes, manifestations, treatments, and prognoses. There are more than 100 types of cancer caused by mutation of cellular genes. Normal cells are limited to about 50 to 60 divisions before they die. Cancer cells do not have a division limit and are considered to be immortal, that is, they keep on dividing, unless they are killed or their host dies.

The progression from a normal cell to a malignant cell follows a pattern of mutation, defective division, abnormal growth cycles, and defective cell communication. Cell mutation occurs when a sudden change affects the chromosomes, causing the new cell to differ from its parent. The malignant cell’s enzymes destroy the glue-like substance found between normal cells, which disrupts the transfer of information used for normal cell structure.

Cancer cells also lack *contact inhibition*. Growth-regulating signals in the cell’s surrounding environment are ignored as the abnormal cell growth increases. Cells continue to divide and invade surrounding tissues.

**Risk Factors**

Increased risk of cancer is linked to many environmental factors. An evaluation of cancer begins with assessment of well-known risk factors such as specific viruses; exposure to radiation, chemicals, and irritants; genetics; diet; hormones; and general immunity. Certain racial and ethnic groups also are at higher risk for some types of cancer (see “Cultural Considerations”).

![NURSING CARE TIP](image)

Teach patients and families that cancer is not contagious.

karkinos—cancer, crab + genesis—birth
Cultural Considerations

Many racial and ethnic groups in the United States have high rates of cancer. Although risk factors for the development of specific cancers are similar, barriers to prevention and nursing strategies to reduce risk factors vary among ethnicities.

**Europeans**

Foreign-born and first-generation white men from Norway, Sweden, and Germany have an increased risk of stomach cancer. This suggests an interrelation among ethnic, geographic, and dietary risk factors. Assessing for these data among these populations may assist in the diagnostic process.

Recent Eastern European immigrants may be at risk for thyroid cancer and leukemia because of the current industrial pollution and radiation exposure from the Chernobyl nuclear disaster in the former Soviet Union in 1986. Some contamination occurred in Estonia, Latvia, Lithuania, and Poland. This may constitute a health hazard and may affect both recent immigrants and visitors to these countries. It is essential for HCPs to carefully screen individuals for these cancers.

**African Americans**

Common cancer sites among African Americans include the prostate, breast, lung, colon, rectum, cervix, pancreas, and esophagus. Because African Americans are overrepresented in the working class, they experience increased exposure to hazardous occupations. For example, African American men are at a higher risk for developing cancer related to their work in the steel and tire industries and in factories manufacturing chemicals and pesticides. They have the highest overall cancer rate and highest overall mortality rate, and their 5-year survival rate is 30% lower than that of European Americans. In general, African Americans report later for treatment than European Americans. Colon tumors may be deeper in African Americans, making detection on digital examination more difficult. Poverty, a diet high in fat and low in fiber, and lower levels of thiamine, riboflavin, vitamins A and C, and iron may increase cancer risk among African Americans. Additionally, cigarette smoking, inner-city living with pollution, obesity, and alcohol consumption increase their risk for developing cancer.

Lack of access to medical care acts as a barrier to prevention among African Americans. Survival, not prevention, is the priority for some. Additional barriers include a lack of cancer risk teaching and detection in some African American communities, lack of health insurance, and little stigma attached to alcohol consumption and smoking. Strong family ties encourage seeking health care advice from family members before professionals.

Primary strategies for preventing cancer and increasing survival among African Americans include using African American professionals as speakers in community activities, using church-based information dissemination, providing forums in African American communities, and addressing smoking advertisements in African American communities. Additional strategies include involving “granny” healers and ministers, changing food preparation practices and amounts rather than changing cultural food habits, involving extended family members in educational campaigns, and using high-profile African American leaders in media campaigns.

**Hispanics**

Hispanic populations in the United States have an increased incidence for some types of cancer. Cervical cancer is increased among Central and South American women. Pancreatic, liver, and gallbladder cancer is increased among Mexican Americans. Many Mexican Americans are less aware of the early warning signs of cancer; many are more fearful of getting cancer than the general public; and many work in mining, factories using chemicals, and farming using pesticides.

Barriers to preventive health care among many Hispanics include high poverty rates, low educational rates, a preference for HCPs who understand Spanish, a preference for health care information presented in Spanish, a delay in seeking treatments for symptoms, and using lay healers as a first choice in health care. Additionally, many have a fear of surgical intervention because the body will be exposed to air, and many have decreased access to health care. For some, an undocumented immigration status creates a fear of reprisal.

Nursing approaches effective among Hispanics include educating lay healers regarding cancer prevention and early warning signs of cancer, using bilingual HCPs, using Hispanic HCPs whenever available, using respected Hispanic community leaders in educational programs, presenting videos in Spanish using Hispanic actors, educating the entire family because of close family networks, and connecting with Hispanic community churches, restaurants, and stores. Additionally, the nurse can use the 1-800-4-CANCER telephone number for Spanish translation and counseling.
Cultural Considerations—cont’d

become involved with Hispanic community movements, and provide information in community and regional Hispanic newspapers and community publications.

**Asians and Pacific Islanders**

Cervical, liver, lung, stomach, multiple myeloma, esophageal, pancreatic, and nasopharyngeal cancers are higher among Chinese Americans. Chinese-American women have a 20% higher rate of pancreatic cancer. High rates of stomach and liver cancer in Korea predispose recent immigrants to these conditions. Thus, the nurse needs to assess and teach newer immigrants regarding these types of cancer.

High rates of stomach, breast, colon, and rectal cancer common among Japanese people may be related to the high sodium content of the Japanese diet, a genetic predisposition, consumption of salted fish and contaminated grain, hepatitis B, cigarette smoking, vitamin A deficiency, low vitamin C intake, and chronic esophagitis. Various barriers to prevention exist: prevention models are not native to their culture; they may lack trust in Western medicine; they have decreased access to health care; some are unable to speak the English language; and for some, an undocumented immigration status creates a fear of reprisal.

Nursing approaches to improve cancer risk prevention among Asians and Pacific Islanders include education about prevention versus acute care practice, educating native healers, involvement in the community with respected native leaders, videos and literature in the native language, and incorporating native healing practices such as traditional Chinese medicine.

**Arab Americans**

Arab Americans are mainly at risk for lung cancer and other cancers related to smoking. Although many Arab Americans are Islamic and Islamic beliefs discourage tobacco use as well as alcohol or drug use, cigarette smoking continues to be a risk behavior among this population. Arab American women are considered very modest, and rates of breast cancer screening and cervical Pap smears are low. Arab Americans tend to lead a sedentary lifestyle with high fat intake, which places them at higher risk for cardiovascular disease as well as certain cancers.

Nursing approaches with this population include promoting awareness and primary prevention strategies. Nurses should encourage cancer screenings and smoking cessation. Because of the modesty of Arab American women, nurses should attempt to ensure that women are given same-sex caregivers to promote breast and cervical cancer screenings.

**American Indians/Native Americans**

American Indian populations have an increased risk for skin, pancreatic, gallbladder, liver, and prostate cancer. Risk factors for the development of cancer include obesity, a diet high in fat, high rates of alcohol consumption, and high rates of smoking. Barriers to prevention include a lack of American Indian HCPs, HCPs’ unfamiliarity with American Indian cultures, lack of financial resources, and a lack of integration of American Indian healing practices into prevention practices.

Nursing approaches to decrease cancer risk prevention among American Indian populations include the following: incorporate prevention into American Indian healing practices; educate American Indian lay healers regarding cancer prevention practices; work with tribal community leaders; respect modesty, gender roles, and tribal customs; work with the Indian Health Service and Bureau of Indian Affairs; encourage traditional customs of physical fitness and exercise; and encourage dietary portion control and healthy food preparation practices instead of changing cultural food habits.

**VIRUSES.** Certain viruses, such as the **oncoviruses** (RNA-type viruses), are linked to cancer in humans. A retrovirus is an enzyme produced by RNA tumor viruses and is found in human leukemia cells.

The Epstein-Barr virus (EBV), which causes infectious mononucleosis, is associated with Burkitt’s lymphoma. Herpes simplex virus 2 has been associated with cervical and penile cancers. Human papillomavirus (HPV) is associated with cervical cancer in women, penile cancer in men, and cancer of the anus and some head and neck cancers in both sexes. Vaccination against HPV (Gardasil®) is recommended for girls and boys age 11 to 12 (Centers for Disease Control, 2013). Chronic hepatitis B is linked with liver cancer.

---

**WORD BUILDING**

**oncovi rus:** onco—mass + virus
UNIT TWO  Understanding Health and Illness

RADIATION. There is an increased incidence of cancer in persons exposed to prolonged or large amounts of radiation. Ionizing radiation involving ultraviolet rays such as sunlight, x-rays, and alpha, beta, and gamma rays plays a major role in promoting leukemia and skin cancers, primarily melanomas.

Persons exposed to radioactive materials in large doses, such as a radiation leak or an atomic bomb, are at risk for leukemia and breast, bone, lung, and thyroid cancer. Controlled radiation therapy is used to treat cancer patients by destroying rapidly dividing cancer cells, but radiation can also damage normal cells. The decision to use radiation is made after careful evaluation of the tumor’s location and vulnerability to other treatments.

CHEMICALS. Chemicals are present in air, water, soil, food, drugs, and tobacco smoke. Chemical carcinogens are implicated as triggering mechanisms in malignant tumor development. Length of exposure time and degree of exposure intensity to chemical carcinogens are associated with risk for cancer development.

Smoking accounts for 90% of lung cancers in men and 80% in women (National Cancer Institute, 2012). Chemical agents, such as those in tobacco, are more toxic when used with alcohol. Alcohol and tobacco are the most frequent causes of cancers of the mouth and throat. Chemicals used in manufacturing, such as vinyl chloride, are associated with liver cancer.

IRRITANTS. Chronic irritation or inflammation caused by irritants such as snuff or pipe smoke often cause cancer in local areas. Nevi (moles) that are chronically irritated by clothing, especially clothing contaminated by chemical residue, can become malignant. Asbestos found in temperature and sound insulation has been proven to cause a particularly destructive type of lung cancer.

GENETICS. Genetics plays a large part in cancer formation. Certain breast cancers are linked to a specific gene mutation. Skin, colon, ovarian, and prostate cancers have a genetic tendency. People with Down syndrome (a chromosomal abnormality) have a higher risk of developing acute leukemia.

DIET. Diet is a major factor in both cause and prevention of malignancies. People who eat high-fat, low-fiber diets are more prone to develop colon cancers. Diets high in fiber reduce the risk of colon cancer. High-fat diets are linked to breast cancer in women and prostate cancer in men. Consumption of large amounts of pickled, smoked, and charbroiled foods has been linked with esophageal and stomach cancers. A diet low in vitamins A, C, and E is associated with cancers of the lungs, esophagus, mouth, larynx, cervix, and breast.

HORMONES. Hormonal agents that disturb the body’s balance can also promote cancer. Long-term use of the female hormone estrogen is associated with cancer of the breast, uterus, ovaries, cervix, and vagina. It has been found that children born of mothers who took diethylstilbestrol (DES) during pregnancy have an increased incidence of reproductive cancers. DES is a synthetic hormone with estrogen-like properties that was used in the past to prevent miscarriage.

Tumors of the breast and uterus are tested for estrogen or progesterone influence. If a breast tumor is malignant, the tumor is tested and treatment varies depending on whether it is positive for estrogen or progesterone dependence.

IMMUNE FACTORS. A healthy immune system destroys mutant cells quickly on formation. An individual with impaired immunity is more susceptible to cancer formation when exposed to small amounts of carcinogens compared with someone with a healthy immune system. Immune system suppression allows malignant cells to develop in large numbers.

Altered immunity is noted in persons with chronic illness and stress. An increased risk of cancer follows a traumatic, stressful period in life, such as the loss of a mate or a job. Failure to decrease stress productively contributes to a higher incidence of chronic illnesses. Thus, a cycle of stress, illness, and increased cancer risk develops. People with acquired immunodeficiency syndrome (AIDS) have a compromised immune system and an increased risk for certain cancers. A decline in the immune system and increase in cancer risk is also noted as the body ages.

Cancer Classification
Cancers are identified by the tissue affected, speed of cell growth, cell appearance, and location. Neoplasms occurring in the epithelial cells are called carcinomas. Carcinoma is the most common type of cancer and includes cells of the skin, gastrointestinal (GI) system, and lungs (Figs. 11.5 and 11.6). Cancer cells affecting connective tissue, including fat, the sheath that contains nerves, cartilage, muscle, and bone, are called sarcomas. Leukemia is the term used to describe the abnormal growth of white blood cells (WBCs). Cancers involving cells of the lymphatic system, lymph nodes, and spleen are called lymphomas. See Table 11.2 for cancer types based on origin.

LEARNING TIP
A person’s cancer risk results from the balance between exposure and susceptibility to carcinogens.

Metastasis (Spread of Cancer)
Neoplastic cells that remain in one area are considered localized, or in situ, cancers. These tumors may be difficult to visualize on clinical examination and are detected
through microscopic cell examination. In situ tumors are often removed surgically and may require no further treatment. **Metastasis** is the term used to describe the spread of the tumor from the primary site into separate and distant areas.

Metastasis is the stage at which cancer cells acquire invasive behavior characteristics and cause the surrounding tissue to change (Fig. 11.7). Metastasis occurs mainly because cancer cells break away more easily than normal cells and can survive for a time independently from other cells. There are three steps in the formation of a metastasis. Cancer cells are able to (1) invade blood or lymph vessels, (2) move by mechanical means, and (3) lodge and grow in a new location.

Metastatic tumors carry with them the cell characteristics of the original or primary tumor site. As a result, surgeons are able to determine the original tumor site based on metastatic cell characteristics. For example, lung tissue found in the brain suggests a primary lung tumor with metastasis to brain tissue. Common sites of metastasis are the lungs, liver, bones, and brain.

**Incidence of Cancer**

Cancer affects all age groups, although the incidence is higher in people aged 60 to 69 years. The second highest age group is ages 70 to 79. Men have a higher incidence of cancer than women. Cancer in people over age 60 is thought to occur from a combination of exposure to carcinogens and weakening of the body’s immune system.

Some cancers, such as Wilms’s tumor of the kidney and acute lymphocytic leukemia, are more common in young people. The cause of tumors in young people is not well understood, but genetic predisposition tends to be a major factor. The most common type of cancer in adults is skin cancer; it is also considered to be the most preventable. Exposure to

**FIGURE 11.7** Invasive metastasis to skin area following mastectomy for breast cancer. Photo courtesy of Dinesh Patel, MD, Medical Oncology, Internal Medicine, Zanesville, OH.
ultraviolet radiation (sunlight) increases the risk of skin cancer. Wearing protective clothing and sunscreen can greatly reduce the risk of skin cancer.

Lung cancer has the highest of the cancer mortality rates in both men and women and also is commonly preventable. Cigarette smoking is the main cause, along with air pollution and exposure to radon and other chemicals.

Men have a high incidence of prostate cancer between ages 60 and 79. Cancer of the colon and rectum has been linked to consumption of high-fat, low-fiber diets and ranks as the third highest cancer in men.

The highest incidence of cancer in women is in the breast. Women with a family history of breast cancer have a greater risk than those with no family history. Commercial testing for the oncogene linked with breast cancer is available and marketed for high-risk women, especially those in the Ashkenazi Jewish population. Genetic testing is done through genetic counseling programs, and the cost ranges from $700 to $2400, depending on the geographic region.

See Figure 11.8 for estimated new cancer cases and deaths for 2013.

Mortality Rates
Cancer survival rates have improved during the past 30 years and, since the 1990s, the number of cancer deaths has decreased for both men and women. A 5-year period is used to monitor cancer patients’ progress following diagnosis and treatment. Survival statistics are based on those who live 5 years in remission. Remission is considered to have occurred when all signs and symptoms of cancer have disappeared, even though there may still be cancer in the body.

For more information about cancer incidence and mortality data, visit the National Cancer Institute website at www.cancer.gov or the American Cancer Society at www.cancer.org.

Early Detection and Prevention
Nurses play an important role in preventing and detecting cancer. You can help educate patients about risk factors, self-examination, and cancer screening programs. Early diagnosis and treatment provide time to stop the progression of cancer.

EARLY DETECTION. Regular physical examinations help HCPs detect early warning signs of cancer. The American Cancer Society recommends mammography (a special x-ray of breast tissue used to detect a mass too small for palpation) is recommended every 1 to 2 years in women after age 40 (some sources say after age 50). The U.S. Preventive Services Task Force (2009), however, recommends beginning mammography at age 50 and screening every 2 years. All women should discuss their individual risk factors and frequency of screening with their physicians. A clinical breast exam is recommended every 3 years for women in their 20s.
and 30s and annually after age 40 (ACS, 2013b). However, if a woman has a high risk for breast cancer because of family history, the type and frequency of screening should be discussed with her doctor.

Initial Papanicolaou testing (Pap smear) for cervical cancer is currently recommended to be gin no later than age 21 and performed every 3 years up to age 29. The preferred approach for women aged 30 to 65 is to have the Pap test with an HPV test, also referred to as cotesting, every 5 years, but it is acceptable to have just the Pap test every 3 years in this age group (ACS, 2013b). After age 65, a woman who has had three normal Pap tests in a row within the past 10 years can choose to stop screening.

Some women choose not to be screened, even when they have access to health care. Barriers to screening include fear of health care personnel and testing procedures, as well as lack of knowledge. Women who fear cancer but trust their HCPs and seek information are more likely to be screened. As a nurse, you can help by developing a trusting relationship and providing information to your female patients.

The ACS considers monthly breast self-examinations to be optional for women and testicular self-examinations to be optional for men. ACS guidelines encourage everyone to be familiar with their bodies and to report changes to their HCPs. Offer men and women instruction in breast and testicular self-examinations if they are interested in doing them.

The ACS (2013b) recommends one of the following options to screen for colorectal cancer, beginning at age 50:

**Tests that find polyps and cancer**
- Flexible sigmoidoscopy every 5 years
- Colonoscopy every 10 years
- Double-contrast barium enema every 5 years
- Colonography (virtual colonoscopy using computed tomography) every 5 years.

**Tests that mainly find cancer**
- Fecal occult blood test every year
- Fecal immunochemical test every year

If any tests are positive, a colonoscopy should be done. Before 2009, the ACS recommended annual digital rectal examination and prostate-specific antigen (PSA) blood testing for men aged older than 50 years with a life expectancy of at least 10 years and for younger men at higher risk. More recently, ACS withdrew this recommendation because routine screening has not been shown to prolong lives (ACS, 2013b). It seems reasonable, however, to still offer these tests as options to men in these populations.

**GENETIC TESTING.** Currently, much attention is directed toward genetic testing and identification of persons at risk for cancer. Genetic testing technology poses both legal and ethical questions concerning confidentiality and insurance cost issues. The cooperation of family members is important because genetic testing is done after a family member has been diagnosed with cancer. Family members may experience a variety of emotions surrounding the increased risk for themselves and their guilt over the role they may have played in increasing the risk for their children.

**HEALTHY LIFESTYLE.** Promotion of healthy lifestyles, including proper diet and exercise, helps strengthen the immune system and reduce cancer risk. Smoking is the most preventable cause of death from lung cancer and smoking cessation is the subject of ongoing campaigns by the American Cancer Society. Secondhand smoke contributes to a significant increased risk of lung cancer in nonsmokers as well.

**PROTECTANT FOODS.** Much research related to diet and cancer risk is being conducted. A diet poor in folate, a B vitamin, can lead to development of cancers of the colon, rectum, and breast. Folate is best obtained by eating fruits, vegetables, and enriched grain products.

People who ingest a diet high in saturated fat are at a greater risk of obesity, which can be a risk factor for colon, prostate, and breast cancers.

A diet rich in vegetables and fruits can reduce the risk of lung, oral, esophageal, stomach, and colon cancer. The ACS recommends eating a variety of fresh fruits and vegetables daily. Because it is not known which compounds in vegetables and fruits are actually beneficial, there are no supplements that can take the place of eating whole foods. Frozen and canned foods can be healthy alternatives, but be careful to read labels for ingredients.

### Nutrition Notes

#### Reducing Cancer Risk

Throughout life, excessive energy (calorie) intake and obesity increase cancer risk.

Proportions of meals should be:
- 2/3 (or more) vegetables, fruits, whole grains, and legumes
- 1/3 (or less) animal protein

Selections should be varied and include:
- Vitamin C rich fruits (e.g., oranges, cantaloupe, strawberries)
- Cruciferous vegetables (e.g., cabbage, broccoli, Brussels sprouts, cauliflower)
- Low-fat dairy products

Consumption of the following should be limited:
- Excessive red meat, especially when
  - processed (smoked, salted)
  - charbroiled or cooked at high temperatures
- Excessive fat, especially saturated fat
- Highly processed carbohydrates
- Recommended alcohol intake, if any, should be limited to one (women) or two (men) standard drinks per day (12 oz. of beer, 5 oz. of wine, or 1.5 oz. distilled spirits)
VACCINES. Preventive vaccines are being developed for cancers associated with specific viruses. Gardasil (a vaccine for HPV) can be given to prevent a variety of cancers, as mentioned earlier.

Most cancer vaccines are therapeutic rather than prophylactic and are used to stimulate the patient’s immune system to destroy cancer cells. Currently, the only therapeutic cancer vaccine approved by the Food and Drug Administration for the treatment of advanced prostate cancer that no longer responds to hormone therapy (ACS, 2013c). Vaccine therapy for malignant melanoma and lymphoma is being tested.

Diagnosis of Cancer

A cancer diagnosis is a frightening experience (see “Patient Perspective”). Often, people try to mask symptoms because they are so frightened of the disease. A physical examination along with careful and thorough assessment of the patient’s current status, medical and surgical histories, and pertinent family history should be completed. The most conclusive information about the health of tissue is acquired by examining cell activity through biopsy.

For explanations of the following tests, see Appendix A.
so many people who care and are concerned enough to take time out of their daily lives to give you support. I’m lucky because my sister is an RN and prepared me for many of the side effects and difficulties. She was also there to help ask questions and get information from other survivors that kept me in a positive frame of mind. I know that without her help and God’s grace and peace, my recovery would not have been so easy. Looking back I can’t really feel all those terrible emotions and symptoms, but I still am afraid of the unknown. It is not easy when it is you and not someone else this happens to.

Now that I’m through the worst part of this, I take positive steps every day to enjoy the little things in life. I feel that the more you keep involved in everyday activities and become educated about the disease and its treatments, the easier it is to deal with. I am taking a drug called tamoxifen now and will be for 5 years. Two of the side effects are hot flashes and sweats. If this is all I have to deal with, however, praise God. My prognosis is very good, and I am expecting a complete cure because I am a survivor.

BIOPSY. Accurate identification of a cancer can be made only by biopsy. Microscopic examination of a sample of suspected tissue or aspirated body fluid can confirm the presence of mutant cells. A biopsy is commonly done in an HCP’s office or outpatient surgery department. See Figures 11.9 and 11.10 for two types of biopsy.

RADIOLOGICAL PROCEDURES. X-ray examination is a valuable diagnostic tool in detecting cancer of the bones and hollow organs. Chest x-ray examination is one diagnostic test used in detecting lung cancer. Mammography is a reliable and noninvasive low-radiation x-ray procedure for detecting breast masses (Fig. 11.11).

Contrast media x-ray studies are used to detect abnormalities of bone and the GI and urinary systems. Contrast media can be given by various methods. Barium is given orally for visualization of the esophagus and stomach or rectally as a barium enema for visualization of the colon. IV injection of contrast media is used for lung and brain scans.

Computed tomography (CT) scans are important in the diagnosis and staging of malignancies and can detect minor variations in tissue thickness. The use of a contrast medium enhances the accuracy of an abdominal CT scan. CT scans are also used to improve the accuracy of inserting a fine needle for biopsy.

NUCLEAR IMAGING PROCEDURES. Nuclear medicine imaging involves camera imaging of organs or tissues containing radioactive media. Radioactive compounds are given intravenously or by mouth. These studies are highly sensitive and
can detect sites of abnormal cell growth months before changes are seen on an x-ray.

Positron emission tomography (PET) scanning provides information about cellular function. Patients are given biochemical compounds, and images are made of the tissue through gamma-camera tomography. PET scans have been useful in brain imaging as well as the detection of the spread of cancers of the lung, ovaries, colon, rectum, and breast.

**ULTRASOUND PROCEDURES.** Ultrasoundography helps detect tumors of the pelvis and breast. Ultrasound also may be used to distinguish between benign and malignant breast tumors.

**MAGNETIC RESONANCE IMAGING.** Magnetic resonance imaging (MRI) is valuable in the detection, localization, and staging of malignant tumors in the central nervous system, spine, head, and musculoskeletal system.

**ENDOSCOPIC PROCEDURES.** An endoscopic examination allows the direct visualization of a body cavity or opening. Endoscopy enables the surgeon to biopsy tissue and is used to detect lesions of the throat, esophagus, stomach, colon, and lungs.

**LABORATORY TESTS.** For normal values for the following laboratory tests, see Appendix B. Blood, serum, and urine tests are important in establishing baseline values and general health status. An elevated white blood cell (WBC) count is expected if the patient has evidence of infection; however, an increase in WBCs without infection raises suspicion of leukemia. Fifty percent of patients with liver cancer have increased levels of bilirubin, alkaline phosphatase, and glutamic-oxaloacetic transaminase.

Bone marrow aspiration is done to learn the number, size, and shape of RBCs, WBCs, and platelets. Bone marrow aspiration is a major tool for diagnosis of leukemia. (See Chapter 27 for a description of this test and related nursing care.) Tumor markers, also called biochemical markers, are proteins, antigens, genes, hormones, and enzymes produced and secreted by tumor cells. Tumor markers help confirm a diagnosis of cancer, detect cancer origin, monitor the effect of cancer therapy, and determine cancer remission. Some examples of tumor markers are shown in Table 11.3.

**CYTOLOGICAL STUDY.** Cytology is the study of the formation, structure, and function of cells. Cytological diagnosis of cancer is obtained mainly through Pap smears of cells shed from a mucous membrane (e.g., cervical, anal, or oral). Test results are based on the degree of cell abnormality. Slight cellular changes are considered normal, with a possible link to abnormal cells seen in infection. Significant cellular changes reflect a higher probability of precancerous or cancerous activity.

**Staging and Grading**

Tumor staging is used to determine the stage of solid tumor masses, providing valuable information to guide treatment plans. The most common system used for staging is the tumor-node-metastasis (TNM) system, an international system that allows comparison of statistics among cancer centers. This staging system classifies solid tumors by size and degree of spread (Table 11.4). For example, a breast cancer staged as T3 N2 MX is a large breast cancer that has spread to regional lymph nodes, but metastasis cannot be evaluated at this time.

The TNM ratings correspond with one of five stages, but stages may differ based on the type of cancer. In general, the lower the number of the stage, the less the cancer has spread. A higher number means a more serious situation exists. In this classification system, stages range from stage 0 (tumor in situ, no in vasion of other tissues) to stage IV (distant metastasis to other sites).

A rating system has also been established to define the cell types of tumors. Tumors are classified according to the percentage of cells that are differentiated (mature). If the tissue of a neoplastic tumor closely resembles normal tissue, it is called well differentiated. A poorly differentiated tumor is a malignant neoplasm that contains some normal cells, but most of the cells are abnormal. The better defined or differentiated the tumor, the easier it is to treat.

**Treatment for Cancer**

There are three main types of treatment for cancer: surgery, radiation therapy, and chemotherapy. To find out more about cancer treatment options, visit the ACS website at www.cancer.org.

SURGERY. Surgery can be curative when it is possible to remove the entire tumor. Skin cancers and well-defined tumors without metastasis can be removed without any additional intervention. For some tumors, as much of the tumor is removed as possible (this is called debulking), and follow-up chemotherapy or radiation is used to treat the remaining tumor cells.

Prophylactic surgery is used to remove moles or lesions that have the potential to become malignant. Colon polyps are often removed to prevent malignancies from developing, especially if the polyps are considered premalignant. An extreme example of prophylactic surgery is a woman who elects to have a mastectomy (surgical removal of the breast) because of a high incidence of breast cancer in her family.

Surgery also may be done for palliation (symptom control). Surgical removal of tissue to reduce the size of the tumor mass is helpful, especially if the tumor is compressing nerves or blocking the passage of body fluids. The goals of palliative surgery are to increase comfort and quality of life.

Reconstructive surgery can be done for cosmetic enhancement or for return of function of a body part. Facial reconstruction is important for a patient’s self-image after removal of head or neck tumors. Women can elect to have breast reconstruction after mastectomy.

Nurses should encourage patients to express and discuss their fears. Patients with a limited understanding of cancer may fear that tissues will not heal postoperatively. Provide information about wound care, including dressing changes and drainage tubes, to increase the patient’s knowledge base and sense of control. Visual aids concerning tumor site and surgical procedures are valuable teaching tools.

Patients who are undernourished are poor surgical candidates and require intervention such as enteral or parenteral nutrition before and after surgery. Patients with cancer also are at increased risk for postoperative deep venous thrombosis (DVT). Preoperative teaching includes the importance of leg movement, early ambulation, wearing antiembolism stockings, and recognizing symptoms of DVT, such as calf redness, warmth, or pain.

RADIATION. Radiation is used commonly in cancer control and palliation, and it can be curative if the disease is localized. The decision to use radiation is commonly based on cancer site and size. Radiation destroys cancer cells by affecting cell structure and the cell environment. It is used in fractionated (divided) doses to prevent destructive side effects; however, side effects can occur in the area being treated because of damage to normal cells.

Radiation can be used before surgery to decrease the size of a large tumor, making surgical intervention more effective and less dangerous, or it can be used after surgery as adjuvant treatment. Palliative radiation is used to reduce the size of a large cancerous lesion and consequently reduce pressure and pain. Radioisotopes can be inserted into cancerous tissue during surgery to help destroy cancerous cells without removing the organ. This is called brachytherapy.

Nursing Care of the Patient Receiving Radiation Treatment. Symptoms of tissue reaction to radiation can be expected about 10 to 14 days after treatment starts and continue for up to 2 to 4 weeks after treatment ends. Typical reactions and appropriate nursing interventions include the following:

- **Fatigue**: Encourage the patient to nap often and prioritize activities. Reassure the patient that the feeling will go away after the treatments are completed.
- **Nausea, vomiting, and anorexia**: Encourage the patient to take prescribed medication for nausea and vomiting. Anorexia can be eased by providing small amounts of high-carbohydrate, high-protein foods and avoiding foods high in fiber.
- **Mucositis** (inflammation of mucous membranes, especially of the mouth and throat): Urge the patient to avoid irritants such as smoking, alcohol, acidic food or drinks, extremely hot or cold foods and drinks, and commercial mouthwash. Advise the patient to perform mouth care before meals and every 3 to 4 hours. A neutral mouthwash can be made by using 1 ounce of diphenhydramine.

hydrochloride (Benadryl) elixir diluted in 1 quart of water or normal saline solution. Agents that coat the mouth, such as calcium carbonate (Maalox), are sometimes used. Lidocaine hydrochloride 2% viscous has an anesthetic effect on the mouth and throat.

- **Xerostomia (dry mouth):** Encourage frequent mouth care. Saliva substitute is available over the counter and is helpful, especially at night when patients describe a choking sensation from extreme dryness.

- **Skin reactions:** These can vary from mild redness to moist desquamation (peeling skin) similar to a second-degree burn. Skin surfaces that are warm and moist, such as the groin, perineum, and axillae, are especially vulnerable. Prophylactic skin care includes keeping skin dry; keeping it free from irritants, such as powder, lotions, deodorants, and restrictive clothing; and protecting it from exposure to direct sunlight. Irradiated skin can be fragile during treatment. It is important to wash these areas gently with mild soap and water, rinse well, and pat dry. The skin may have markings or tattoos to delineate the treatment field. Take care not to wash off the markings.

- **Bone marrow depression:** Low blood cell counts occur with both radiation and chemotherapy because they can attack all rapidly dividing cells, not just cancer cells. Weekly blood cell counts are done to detect low levels of white blood cells, red blood cells, and platelets. Transfusions of whole blood, platelets, or other blood components may be needed.

### Safety Considerations

Radiation may be administered externally or internally. External radiation is given by a trained medical specialist in a designated area in a hospital or clinic. Patients receiving external radiation do not emit radioactive material and do not require any safety precautions before or after treatment.

Internal radiation is administered to patients admitted to a health care facility. Safety guidelines must be followed when caring for a patient with internal radioactive materials that have been implanted into tissue or body cavities or administered orally or intravenously, because the patient will be radioactive. Nursing responsibilities include knowledge about the following:

- Radiation source being used
- Method of administration
- Start of treatment
- Length of treatment
- Prescribed nursing precautions

Personnel involved with radiation therapy must recognize three primary factors to protect themselves: time, distance, and shielding. These three factors depend on the type of radiation used. **Time** involves the time spent administering care, **distance** involves the amount of space between the radioisotope and the nurse, and **shielding** involves the use of a barrier such as a lead apron.

You must work efficiently when caring for patients who are receiving radioisotopes that are releasing gamma rays. Your exposure to radiation is proportionate to the time spent and the distance from the radiation source. For example, you will receive less exposure standing at the foot of the bed of a patient with radioisotopes inserted into the head than if you stand at the head of the bed (Fig. 11.12). Principles of time and distance are used to protect the nurse, visitors, and other personnel.

It is important to teach the patient and family members the reason nursing care focuses on providing only essential care. Speedy nursing encounters and visitor restrictions are better
accepted and less likely to promote feelings of isolation when patients understand the reasons behind them.

Drainage from the site of a radioactive colloid injection is considered radioactive, and the HCP must be informed immediately if it occurs. Dressings contaminated with radioactive seepage must be removed with long-handled forceps. Radioactive materials must never be touched with unprotected hands; shielding is required to prevent exposure to radiation. Contamination from radioisotope applicators or interstitial implants cannot occur when the capsule is intact; contamination occurs when the capsule is broken.

**BE SAFE!**

**BE VIGILANT!** Remember to use the principles of time, distance, and shielding to protect yourself from radiation exposure.

**CHEMOTHERAPY.** Chemotherapy is chemical therapy that uses cytotoxic drugs to treat cancer. Cytotoxic drugs can be used for cure, control, or palliation of cancerous tumors. They are classified according to how they affect cell activity. Examples of specific drugs are listed in Tables 11.5 and 11.6.

The effects of chemotherapy are systemic unless used topically for skin lesions. Chemotherapy is used preoperatively to shrink tumors and postoperatively to treat residual tumors. Tumor type and genetics influence the effectiveness of chemotherapy. Age is also a consideration, but treatment should be based on physiological age rather than chronological age. That is, just because a patient might be 70 years old doesn’t mean his body is the same as that of other 70-year-olds.

**Combination Chemotherapy.** In this kind of therapy, two or more antineoplastic agents are used together to treat the patient’s cancer. This can expose a larger number of cells at

*Continued*
different points in the cell cycle to chemotherapy. Combining drugs also decreases the side effects of therapy and decreases the possibility of the tumor becoming resistant to the therapy. For drugs to be combined this way, several criteria must be met. Each drug must be effective when used alone to treat the cancer, and each must have a different toxicity that would limit its use. For example, if three drugs that are all cardiotoxic are given, the patient is more likely to develop cardiotoxicity. Patients are still monitored for toxic effects from the treatment as well as improvement in their status.

**Routes of Administration.** Chemotherapy can be given by the oral, intramuscular, IV, or topical route. The dosage is determined by the size of the patient and the toxicities of the drug. IV administration requires specialized training and knowledge of antineoplastic drugs.

**Vesicant** drugs are given only by the IV route into a large vein. These drugs cause blistering of tissue that eventually leads to necrosis if they infiltrate, or leak, out of the blood vessel and into soft tissue (Fig. 11.13). Skin grafts may be needed if tissue damage is extensive.

</table>

Note: Cyclophosphamide (Cytoxan) can also be administered by the oral route. PSA, prostate-specific antigen; PT, prothrombin time; RBC, red blood cell; WBC = white blood cell count.

*WORD BUILDING*

*vesicant*: vesicate—to blister
Affect all rapidly growing cells. Fast-growing epithelial cells, such as those of the hair, blood, skin, and GI tract, are usually the most affected by both chemotherapy and radiation.

**Hematologic System.** Chemotherapy is toxic to bone marrow, which is where blood cells are produced. The number of blood cells (especially white cells) drops after approximately 7 to 14 days of chemotherapy, depending on the drug. This period when the cell counts are lowest is called the *nadir* and is when patients are most at risk for complications. Patients may develop low WBC counts (*leukopenia*), increasing their susceptibility to infection and sepsis. Sometimes this is called *neutropenia* because neutrophils are the most plentiful white cells. A reduction in platelets (*thrombocytopenia*) increases the risk of bruising and bleeding and can require platelet transfusions. Increased risk of *anemia* occurs with the reduction of RBCs and may require blood transfusions. See Table 11.7 for medications that can be used to stimulate production of these cells.

**Table 11.7 COLONY-STIMULATING FACTORS**

<tr>
<td><strong>Interleukin-11</strong></td>
<td>oprelvekin (Neumega)</td>
<td>Watch for fluid retention. Monitor CBC, platelet count. Teach subcutaneous administration if drug will be given at home.</td>
</tr>
</tbody>
</table>

**Note:** Because these drugs are proteins, they all require refrigeration, and you cannot shake them. Many thousands of dollars have been lost because a drug was not returned to the refrigerator when it was not used. Be sure to check package instructions. CBC = complete blood count.
Gastrointestinal System. Because the lining of the GI tract is made up of rapidly dividing cells, it is susceptible to the toxicity of chemotherapy drugs. Patients often experience nausea, vomiting, and diarrhea. Stomatitis (inflammation of the mouth) is a common complaint and is discussed under side effects of radiation. These side effects can be controlled with medication.

Hair. Alopecia, or hair loss, is common with many, but not all, chemotherapeutic drugs. This is a temporary condition, and growth of the new hair usually starts when the chemotherapeutic medication is stopped. Alopecia involves the entire body and includes eyebrows, eyelashes, and axillary and pubic hair. Hair that regrows may be a different color or texture than the original hair. It is not uncommon for individuals who originally had straight hair to regrow curly hair.

Neurologic System. Drugs may affect the neurologic system. An adverse reaction to vincristine (Oncovin) is neurotoxicity, which can result in tingling or numbness in the extremities and in severe cases can cause footdrop from muscle weakness.

Other Systems. Less common complications include renal toxicities, such as pain and burning on urination, and hematuria. Doxorubicin (Adriamycin) has been associated with permanent heart damage, and bleomycin can cause pulmonary fibrosis.

Severe toxic side effects can be controlled by carefully limiting the amount of medication given and constantly monitoring the patient for complications.

CYTOPROTECTIVE AGENTS. Cytoprotective agents protect healthy cells from some side effects of certain chemotherapeutic drugs. For example, dexrazoxane helps prevent cardiac damage associated with doxorubicin. Amifostine (Ethyol) helps protect the kidneys from platinum-based chemotherapy. It also protects normal cells in parts of the body against damage from radiation treatments. Mesna (Mesnex) protects the bladder against chemotherapy drugs such as cyclophosphamide (Cytoxan).

New Treatments Being Researched

New therapies for cancer are constantly being researched. For example, hyperthermia has been used with radiation and chemotherapy. It has been beneficial in some types of cancer but is usually used only in investigational studies.

Biological response modifiers (such as interferons) are drugs used to stimulate the immune system. These drugs are used commonly for specific types of cancer and have produced some beneficial results. They are also being used in many investigational studies. Go to www.cancer.gov for information on current clinical trials.

Data Collection

NURSING PROCESS FOR THE PATIENT WITH CANCER

Patients with cancer are assessed for many problems associated with the disease and its treatment. Thorough assessment will help the health team build a plan of care relevant to the patient’s needs.

The nurse should monitor laboratory studies. Potential for bleeding exists when the platelet count is 50,000/mm³ or less; risk for spontaneous bleeding occurs when the count is less than 20,000/mm³. Monitor the WBC count for risk of infection and the RBC count for anemia.

Monitor the patient’s weight, and note reports of nausea, changes in taste, vomiting, and diarrhea related to either the disease or treatment. Monitor the oral mucosa for lesions or inflammation. Also watch for signs of dehydration. “Nutrition Notes—Assessing the Need for Nutritional Support” presents criteria for determining whether a patient needs nutritional support.

Reproductive System. The effects of chemotherapy or radiation can cause temporary or permanent changes in the reproductive system. Chemotherapy can damage sperm and ova. Issues concerning fertility should be discussed with the patient before treatment. Measures such as freezing ova and using a sperm bank can provide options for the patient and his or her partner. Patients should also talk to their HCPs before engaging in intercourse during chemotherapy and use protection against pregnancy.

• WORD • BUILDING •

stomatitis: stoma—mouth + itis—inflammation
Nutrition Notes

Assessing the Need for Nutritional Support

Intensive nutritional support may not benefit all cancer patients because the tumor interferes with the patient’s utilization of nutrients. Clinical judgment is required to analyze the patient’s needs and expected response. In general, if any of the following findings are present, you should talk with the dietitian or HCP about the need for nutritional support.

- Weight 5 kg (11 lb) below a healthy body weight
- Intolerance of oral/enteral feedings for more than 7 days
- Serum albumin level of less than 3 g/dL
- Location of cancer in head and neck or GI system
- Severe GI injury in patients with cured/controlled cancer

Psychosocial issues related to cancer are as varied as the persons afflicted with the disease. Help the patient explore perceptions about quality of life. Culture and age affect cancer perceptions. Assess the patient’s ability to cope and coping strategies that have been effective in the past. Determine what information the patient has received and understands about his or her disease and prognosis.

Assess the roles of the patient and caregiver in the family. Be aware of whether the caregiver can be at home or whether he or she must work outside the home and also care for the patient. Isolation can be either self-imposed or imposed by friends and family as terminal illness issues are confronted. It can be very distressing to see a loved one decline with cancer; often people say they are “afraid of saying or doing the wrong thing” so they “just stay away.” Listen for cues from patients expressing self-blame, anger, or depression. It is important to recognize signs of depression and suicidal tendencies.

Assess for fatigue and anxiety in a patient being treated for cancer. A decline in sexual desire is not uncommon during cancer treatment. Assess for anxiety about sexual intercourse, including fears concerning contracting cancer from the patient and fears that sexual intercourse will make the cancer worse.

Assess the patient’s feelings about any actual or perceived change in appearance due to surgery, radiation, or chemotherapy.

Nursing Diagnoses, Planning, and Implementation

See the “Nursing Care Plan for the Patient With Cancer” for top nursing care priorities. Additional nursing diagnoses are presented below.

NURSING CARE PLAN for the Patient With Cancer

**Nursing Diagnosis:** Risk for Ineffective Coping related to the diagnosis and treatment of cancer as evidenced by behaviors such as denial, isolation, anxiety, and depression

**Expected Outcomes:** Patient will cope effectively as evidenced by identifying stressors related to illness and treatment; communicating needs, concerns, and fears; and use of appropriate resources to support coping.

**Evaluation of Outcomes:** Is patient able to identify stressors and communicate concerns? Does patient effectively draw on past coping mechanism? Does patient have and appropriately use support systems?

**Intervention** 

Assess effective coping mechanisms used in the past and currently available to the patient. 

**Rationale** Coping mechanisms that worked in the past may be helpful again, and the nurse can support appropriate choices. 

**Evaluation** Is the patient able to identify and draw on past coping mechanisms?

**Intervention** 

Use active listening skills to encourage the patient to express feelings and fears. 

**Rationale** The patient must identify fears to be able to cope effectively with them. 

**Evaluation** Does the patient identify fears and concerns?

**Intervention** 

Assess the meaning of quality of life to the patient. 

**Rationale** Once identified, the nurse can assist the patient to achieve quality-of-life goals. 

**Evaluation** Is the patient able to identify the meaning of quality of life? Are there ways the nurse can assist the patient to reach quality-of-life goals?

**Intervention** 

Assess for suicide risks. 

**Rationale** A patient who feels hopeless may be at risk for suicide. 

**Evaluation** Is the patient at risk? Are suicide precautions necessary?

Continued
**NURSING CARE PLAN for the Patient With Cancer—cont’d**

**Intervention** Explore outlets that promote feelings of personal achievement. **Rationale** Personal achievement promotes self-esteem. **Evaluation** Does the patient have creative outlets that promote feelings of achievement? Can the nurse assist in implementing these activities?

**Intervention** Consider the use of humor. **Rationale** Humor can be both distracting and therapeutic. **Evaluation** Does the patient use humor? Does it provide temporary distraction from concerns?

**Nursing Diagnosis:** _Acute Pain or Chronic Pain_ related to tissue injury from disease process and treatment

**Expected Outcomes:** Pain will be prevented and patient will be comfortable at all times as evidenced by patient stating pain is at an acceptable level on pain scale.

**Evaluation of Outcomes:** Does patient state pain is controlled?

**Intervention** Assess the patient’s pain including onset, location, duration, character, and aggravating and alleviating factors. **Rationale** Assessment provides direction for the treatment plan. **Evaluation** Is assessment complete and used to guide treatment?

**Intervention** Ask patient to rate pain on a scale from 0 to 10 (0 = absence of pain; 10 = worst pain). **Rationale** A pain rating should guide treatment and evaluate effectiveness of treatment. **Evaluation** Does patient use pain assessment scale effectively? Is patient in pain?

**Intervention** Administer analgesics as ordered, around the clock (ATC). (See “Evidence-Based Practice” box.) **Rationale** Using an ATC schedule prevents pain from becoming severe. **Evaluation** Is patient’s pain kept under control at all times?

**Intervention** Check pain relief within 1 hour of administration of medication and every 2 to 4 hours. **Rationale** Alternative short-acting medications may be necessary for breakthrough pain. **Evaluation** Is breakthrough pain present? Does long-acting analgesic need to be increased to prevent pain?

**Intervention** Educate patient on use of patient-controlled anesthesia (PCA). **Rationale** PCA allows the patient to be in control of own pain relief. **Evaluation** Does PCA keep patient pain free and able to participate in desired activities?

**Intervention** Monitor level of sedation and respiratory status if opioid dose is increased. **Rationale** Patients who receive long-term opioid therapy develop a tolerance to the depressant effects of opioids. **Evaluation** Is patient alert with respiratory rate between 12 and 20?

**Intervention** Explain the use of non-pharmacological interventions such as relaxation once the pain is controlled with medications. **Rationale** Nonpharmacological interventions supplement but do not replace analgesics. **Evaluation** Does patient use non-pharmacological interventions? Do they help?

**Nursing Diagnosis:** _Risk for Infection_ related to diminished immunity and bone marrow suppression as a result of chemotherapy or radiation

**Expected Outcomes:** The patient will be free and safe from infection as evidenced by being afebrile and stating self-care measures to protect from infection. Signs and symptoms of infection are identified and treated early.

**Evaluation of Outcomes:** Are signs and symptoms of infection absent? If present, are they reported quickly? Can the patient identify self-care measures for preventing infection?
NURSING CARE PLAN for the Patient With Cancer—cont’d

**Intervention** Promote good hand-washing technique before interaction with the patient. **Rationale** Appropriate hand hygiene can reduce the transmission of antimicrobial organisms. **Evaluation** Are you careful with your hand washing? Have you also instructed the patient, family, and nursing assistants about careful hand washing?

**Intervention** Monitor body temperature every 4 hours. **Rationale** Elevated body temperature is an early sign of infection. **Evaluation** Is body temperature within normal limits?

**Intervention** Monitor WBC count daily. **Rationale** For the neutropenic patient, the WBC will not be elevated. Neutropenia is a risk factor for infection. **Evaluation** Is the WBC count 5000 to 10,000/mm³?

**Intervention** Assess for signs of inflammation or drainage at potential infection sites, such as old aspirate sites, venipuncture sites, oral and rectal mucosae, perineal area, axillae, incisions, pierced earlobes, under breasts, and between toes. **Rationale** Intact skin is the first line of defense against invading microorganisms. **Evaluation** Are there any sites that need special care to maintain skin integrity?

**Intervention** Watch for signs of respiratory infection, such as sore throat, cough, shortness of breath, and sputum production. **Rationale** Hospital-acquired pneumonia has high morbidity and mortality rates. **Evaluation** Are signs of respiratory infection present?

**Intervention** Assess for signs of urinary tract infection (UTI) including burning, pain, urgency, blood in urine. **Rationale** Genitourinary tract is the most common site for hospital-acquired infection. **Evaluation** Are signs of UTI present?

**Intervention** Teach administration of G-CSF or GM-CSF as ordered. **Rationale** These medications help the body produce more WBCs. The patient may need to administer it subcutaneously at home. **Evaluation** Does patient demonstrate correct self-administration? Is WBC count improving?

**Intervention** Limit visitors to only healthy adults. **Rationale** Viral infection in an immunosuppressed patient has a high mortality rate. **Evaluation** Are the patient and family aware of visiting restrictions and rationale? Is there a sign on the door reminding visitors?

**Intervention** Teach patient to ask HCP about avoiding unwashed, unpeeled fruits and vegetables. (See “Nutrition Notes.”) **Rationale** Unwashed or unpeeled fresh fruits and vegetables can carry pathogens. **Evaluation** Are the patient and family aware of the risks of eating unwashed, unpeeled fruits and vegetables?

**Intervention** Keep fresh flowers and potted plants out of the patient’s room. **Rationale** Aspergillus is a fungus found in soil and water and can cause pneumonia. **Evaluation** Is the room free from potential sources of infection?

---

**EVIDENCE-BASED PRACTICE**

**Clinical Question**
Is oral morphine effective for cancer pain?

**Evidence**
A review of 54 studies found that various formulations of oral morphine were effective at relieving cancer pain but had unwanted side effects—primarily constipation, nausea, and vomiting (Wiffen & McQuay, 2007).

**Implications for Nursing Practice**
Administer oral morphine as ordered for pain. Be sure to institute preventive measures against constipation before it becomes a problem. Talk with the HCP about medications for nausea if it occurs.

**REFERENCES**

Ineffective Protection related to thrombocytopenia associated with chemotherapy and radiation

**Expected Outcome:** The patient will be free of bleeding as evidenced by stable blood counts and the absence of bruising or frank bleeding.

- Monitor platelet counts. A platelet count of less than 50,000 indicates potential for bleeding.
- Teach self-administration of oprelvekin as ordered. Oprelvekin stimulates production of platelets.
- Test all urine and stool for occult blood to detect the presence of blood.
- Avoid giving intramuscular, subcutaneous, or rectal medications. Medications given via invasive routes can cause bleeding.
- Apply pressure for at least 5 minutes to venipuncture or injection sites. Pressure for a longer time is needed at sites of invasive procedures to stop bleeding.
- Teach the patient about gentle mouth care including no flossing, a soft toothbrush, and wearing properly fitting dentures to help prevent trauma and bleeding.
- Avoid trauma to rectal tissue by avoiding rectal temperatures and enemas. Teach importance of avoiding anal intercourse. Trauma to rectal tissue can cause bleeding.
- Instruct the patient not to take any salicylates or non-steroidal anti-inflammatory drugs because they can interfere with platelet function and cause bleeding in the GI tract.
- Observe for bruising, petechiae, bleeding gums, tarry stools, and black or coffee-ground appearing emesis. These are signs of bleeding.
- Advise the patient to use an electric razor to decrease risk for trauma and bleeding.
- Teach the patient to avoid forcefully blowing his or her nose or inserting objects into the nose to reduce trauma to nasal mucosa to prevent spontaneous bleeding.
- Teach the patient to monitor for bleeding with intercourse because of the risk of trauma to tissues.

Imbalanced Nutrition: Less Than Body Requirements associated with disease, pain, and treatment

**Expected Outcome:** The patient will have caloric intake that is adequate to meet body requirements and balanced intake and output, as evidenced by stable weight and albumin level of 3 g/dL or greater.

- Monitor food and fluid intake and output every 8 hours. This will provide objective data for the amount of nutrients and fluids taken in.
- Weigh the patient daily. Weight is an objective measurement to determine if intake is adequate enough to maintain weight.
- Consult a dietitian for dietary supplements. Dietitians can calculate the calories needed for adequate nutrition and make recommendations for supplements.
- Consult with the primary care provider for medications to control nausea, vomiting, and diarrhea. If these symptoms are controlled, then the patient is better able to eat.
- Keep the environment free of strong odors, such as disinfectants, perfumes, deodorizers, and body wastes. Strong odors can induce nausea.
- Provide room-temperature or cold foods and clear liquids. These foods have fewer odors and may be more comfortable for the patient to eat.
- Offer sour foods such as hard candy and lemon. These can help control nausea.
- Encourage listening to music or doing relaxation exercises. These can provide distraction from pain and nausea.
- Add nutmeg to foods. Nutmeg may help slow the motility of the GI tract and decrease the risk of nausea and vomiting.
- Provide mouth care before meals. Oral care allows for a better taste in the mouth, and saliva is needed for digestion of food.
- Provide small, high-calorie meals. Eating smaller, more frequent meals prevents the patient from feeling full and nauseated.
- Administer pain medication before meals to help reduce the impact of pain on appetite.
- Instruct the patient to avoid fluids with meals to prevent premature feelings of fullness.
- Teach the patient to avoid exercise before meals. If the patient is fatigued, he or she will not have the energy to eat and digest food.

See “Nutrition Notes—Treating Problems Related to Nutrition” for additional nutrition interventions.

### Nutrition Notes

#### Treating Problems Related to Nutrition

**Early Satiety and Anorexia**

- Select nutrient-dense foods. For example, fortify puddings and milkshakes with dry skim milk powder.
- Encourage appropriate exercise.
- Present food attractively.
- Offer small, frequent meals.
- Encourage family to provide home-cooked food.
- If meals are not tolerated, offer 1 oz of a complete nutritional supplement every hour.

**Bitter or Metallic Taste**

- Provide oral hygiene before meals.
- Cook in glass containers in a microwave oven.
- Use nonmetallic utensils when eating meals.
- Serve food cold or at room temperature.
- Offer lemon-flavored beverages.
- See if the patient prefers eggs, fish, poultry, and dairy products to beef and pork.
• Experiment with sauces and seasonings. Sweet sauces and marinades may improve the palatability of meats.

**Local Oral Effects**

• *Ulcerations:* Offer soft, mild foods; cream sauces, gravies, and dressings for lubrication; cold foods for numbing; and straws for liquids. Avoid hot items, salty or spicy foods, and acidic juices. If an anesthetic mouthwash is prescribed, the mouth may be numb; caution the patient to chew carefully to avoid biting the lips, tongue, or cheeks.

• *Dry mouth:* Offer frequent sips of water or artificial saliva. Lubricate with gravies, butter, margarine, milk, cream, or bouillon. Sugarless hard candy, chewing gum, or popsicles may stimulate saliva production.

• *Dysphagia:* Teach the patient to make swallowing a conscious act (inhale, swallow, exhale) and to experiment with head position. Offer foods with a smooth, even consistency. Thick liquids are easier to swallow than thin. Encourage dunking breads in a beverage to soften.

**Nausea and Vomiting**

• Administer antiemetics on a regular prophylactic schedule.

• Suggest dry crackers.

• Offer liquids between instead of with meals to reduce stomach volume, and low-fat meals to facilitate stomach emptying.

• Remove covers from food containers away from the bedside if strong odors disturb the patient’s appetite.

• Instruct the patient to chew thoroughly, eat slowly, and rest afterward.

• Arrange meal schedule to take advantage of times when patient feels better.

• Avoid serving favorite foods when the patient is nauseous to avoid an association between those foods and vomiting.

**Diarrhea**

• Suggest a low-fiber diet.

• Try a lactose-free diet for temporary lactose intolerance.

• Propose pectin-containing foods (apples, strawberries, citrus fruits) to absorb water in the bowel.

• Investigate the feasibility of probiotic therapy to repopulate intestine (see below).

• Consult with a dietitian about special feedings.

**Altered Immune Response**

• Institute protective isolation to minimize exposure to microorganisms.

• Observe strict procedures for food safety and sanitation.

• Some providers attempt to limit exposure to microorganisms by restricting unpasteurized, uncooked, and unwashed foods but the effectiveness of this dietary approach has not been substantiated with direct proof (Fox & Freifeld, 2012).

**Self-Care Deficit related to weakness and fatigue**

**EXPECTED OUTCOME:** Care needs will be met at all times as evidenced by statement that needs are being met by self or caregiver.

• Assess what self-care activities the patient can do independently (bathing, grooming, feeding, toileting, ambulating). By assessing what the patient can do independently, you can develop goals and interventions appropriate for the patient.

• Identify and include the patient’s strengths in self-care activities to help increase the patient’s independence.

• Provide the tools needed for the patient to assist with his or her own bathing, grooming, feeding, toileting, and ambulation. Physical and occupational therapy departments may be able to help identify assistive devices. *Adaptive and assistive devices can promote independence.*

• Teach the patient about options available for when he or she is no longer able to care for his or her own needs. *Support from other sources will help the patient conserve energy.* Planning ahead can help reduce anxiety.

• Instruct family members in how to assist in daily care. *Allowing family members to assist in the daily care will promote their role as caregivers.*

• Consult home health care or hospice nurses to assist with care needs upon discharge from the acute setting. *Support from these sources will assist the patient to maintain dignity when independence is no longer possible.*

**Risk for Ineffective Role Performance related to needs of patient and anticipated outcome**

**EXPECTED OUTCOME:** The caregiver will be prepared to provide care effectively as evidenced by (1) identification of resources available to assist in providing care for the patient and (2) maintenance of caregiver’s physical and emotional health.

• Observe the caregiver’s ability to provide care for the patient. *The nurse needs to know if the caregiver will be able to handle the care needs.*

• Observe the quality of the relationship between the patient and caregiver. *The quality of the relationship impacts the care delivered.*

• Actively listen to the caregiver’s concerns. *Doing so can assist the nurse in assessing the caregiver’s ability to cope and can help in planning care.*

• Teach appropriate caregiving skills as needed. *The caregiver may not be aware of how to bathe a patient or how to provide basic or advanced care.*
UNIT TWO  Understanding Health and Illness

• Assist the caregiver to identify available supports. Assistance can provide a break and decrease the risk of exhaustion and depression in the caregiver.
• Instruct the caregiver in the resources available in the community. Support groups can help the caregiver by providing an outlet for sharing concerns and finding support.
• Consult the multidisciplinary team to provide the services needed at time of discharge. Preparing the caregiver for discharge needs/care with the proper resources will help the caregiver feel empowered to deliver the care.
• Watch for signs of depression in the caregiver, and intervene to help coping. The caregiver can develop a weakened immune system secondary to stress and depression.
• Arrange for respite for the caregiver or encourage the caregiver to utilize this service. Respite care can provide a break for the caregiver.
• Encourage the caregiver to grieve over the patient. Caregivers will grieve for the loved one’s loss of function or role in the family, even before death.
• Assist the caregiver with ways to decrease stress. Encouraging caregivers to take time to care for themselves will leave them with the energy they need to continue providing care.

Social Isolation related to changing relationships

EXPECTED OUTCOME: The patient will manage social isolation as evidenced by (1) ability to identify feelings of isolation and (2) ability to participate in chosen activities.

• Observe the patient for signs of barriers to social interaction, such as incontinence, lack of transportation, and inadequate money or support system. Why a patient feels isolated can vary from one person to another, but knowing the reason can help the nurse plan appropriate interventions.
• Discuss causes of perceived or actual isolation. How the patient is dealing with the illness will have an impact on how he or she manages the illness.
• Listen to the patient describe reasons for isolation. Listening and being present are ways to show caring.
• Promote opportunities for the patient to interact socially, such as at mealtimes or during therapy sessions. The patient will feel less isolated if given an opportunity to participate in diversional activities.
• Provide positive reinforcement when the patient starts conversation with others. Positive feedback from the nurse can have an impact on the patient’s confidence.
• Provide information about support groups, and encourage the patient to contact them. Support groups can help the patient cope better with stressful events in life.

Ineffective Sexuality Pattern related to change in body functions

EXPECTED OUTCOME: The patient will have knowledge about limitations or changes in sexual activity during cancer treatment as evidenced by statement of understanding.

• Provide a private environment to discuss issues of sexuality. Privacy promotes a comfort level that allows the patient to express concerns.
• Assess what the patient understands about sexuality during cancer treatment. This discussion can clear up any misinformation the patient and partner may have.
• Encourage the patient to discuss concerns about sexuality with his or her partner. Communication is a key component of emotional intimacy.
• Stress to the patient that cancer cannot be passed from person to person through sexual intimacy. Cancer is not contagious.
• Instruct the patient that sexual activity is usually safe during and after cancer treatment. Sexual activity does not necessarily hurt the patient.
• Advise the patient to abstain from sexual intercourse while the blood count is low to prevent secondary infections and bleeding. A low white blood cell count can raise the risk of infection, and a low platelet count can raise the risk of bleeding.
• Advise men to ask their primary care provider about using condoms for intercourse during chemotherapy because some chemotherapy agents can be found in semen.
• Arrange for respite for the caregiver or encourage the caregiver to utilize this service. Respite care can provide a break for the caregiver.
• Assist the caregiver to identify available supports.
• Promote opportunities for the patient to interact socially and participate in chosen activities.

Disturbed Body Image related to cancer and its treatment (e.g., surgical procedures such as mastectomy, ostomy, or loss of hair from chemotherapy)

EXPECTED OUTCOME: The patient will be able to accept the changes in body image as evidenced by willingness to participate in care and adjust to changes in lifestyle.

• Allow the patient to discuss feelings of anger or depression, and confirm that these feelings are normal when adjusting to body changes. A patient may be better able to cope with body changes if he or she can talk about feelings and understand that they are normal.
• Encourage the patient to select a wig before hair loss so the patient can find one resembling his or her own hair color and style.
• Provide education, and urge the patient to care for the ostomy site or surgical wound when ready to promote independence.
• Provide information about resources such as Reach to Recovery (www.cancer.org; type in Reach to Recovery) and Look Good . . . Feel Better support groups (www.lookgoodfeelbetter.org). Support groups provide a forum for patients to share their experiences with others undergoing similar changes.
• Provide information about community assistance and financial aid for programs or services. Social workers can help with community resources that can provide equipment or supplies for the patient.
**Grieving related to diagnosis and potential disease outcome**

Grieving and end-of-life care are covered in depth in Chapter 17.

**Evaluation**

If the interventions have been effective, the patient will have no unusual bleeding or bruising. The patient and family will be knowledgeable about risk factors for bleeding and about signs of bleeding to report promptly.

The patient will be nourished and maintain weight within normal limits. The patient will maximize the potential for self-care activities. The patient and caregiver will know about available resources to assist with self-care activities in the home setting. Caregivers will know how to provide care for the patient. The patient will be able to openly discuss feelings and be able to spend time with family and loved ones to resolve any issues.

Effective interventions will allow the caregiver to make use of resources in the community to assist with patient care and to maintain her or his own physical and psychological health while caring for the patient. The patient will be able to discuss feelings of isolation and seek out activities to participate in. The patient will maintain a healthy self-esteem and be able to discuss feelings openly and honestly with her or his partner.

The patient will be able to openly discuss concerns regarding body changes and be able to maintain control of his or her body. The patient will know about community resources and support groups to assist with needs related to body image.

**CRITICAL THINKING**

**Mrs. Jones**

- Mrs. Jones is admitted to your unit after a simple mastectomy for breast cancer. The tumor was staged as a T2, N0, M0. A bone scan was negative for metastasis. She is scheduled for four chemotherapy treatments, 3 weeks apart. The medications prescribed are high doses of doxorubicin and cyclophosphamide. A central line is inserted for chemotherapy.

1. What does the staging of Mrs. Jones’s tumor mean?
2. What major side effects of her medications should you look for?
3. Why was a central line inserted?
4. What nursing diagnoses are appropriate for Mrs. Jones?

*Suggested answers are at the end of the chapter.*

**SURVIVORSHIP**

Millions of people around the world are no longer dying from cancer but rather are survivors of the disease. There are an estimated 13.7 million cancer survivors in the United States alone (NCI, 2012). Cancer survivors deal with emotional and physical effects of their disease and treatment.

Survivorship begins at the time of the diagnosis and continues even after treatments have been completed. In 2011, the Commission on Cancer of the American College of Surgeons published new accreditation standards relating to care of patients with cancer. The development of a survivorship plan of care that not only documents the care provided but also addresses the improvement in the quality of life of the cancer survivor is one of the key components for accreditation. Focus is on reassessment of psychosocial needs at the time of completion of treatment to create a survivorship plan of care for continued medical follow-up as well as management of emotional and social challenges. Cancer centers around the country with strong support from their patient and family advisory councils and advocacy groups are developing survivorship programs. For further information about cancer survivorship programs, see the American College of Surgeons website: www.facs.org/cancerprogram/index.html.

**HOSPICE CARE OF THE PATIENT WITH CANCER**

Patients who are considered terminal and have a life expectancy of 6 months or less are eligible for hospice care, which provides humanistic care for dying people and their families. The dying person is provided care at home or in a homelike setting that promotes comfort and quality of life until death. Hospice care is offered as an inpatient or outpatient service (see “Home Health Hints”).

**Home Health Hints**

- The home health or hospice nurse helps manage cancer pain in the home. Oral, transdermal, or IV analgesics are preferred. For moderate to severe pain, doses should be given around the clock with as-needed doses for breakthrough pain. Intramuscular delivery of pain medication should be avoided because of the pain of the injections and the burden it places on the caregiver.
- The nurse should anticipate constipation from opioid administration and treat prophylactically.
- Some patients are fearful of taking prescribed pain medications. Explain the importance of taking the medications as ordered and note that it is easier to maintain pain relief than to reverse severe pain.
- Home health nurses are in key positions for making timely referrals for hospice care. Eligible patients are those who have a life expectancy of 6 months or less and who have a desire for supportive palliative care rather than continued treatments. To have hospice care in their own home, they must also have a friend or relative who is willing to coordinate the care.
Inpatient services are used for symptom control and respite care for the family. Family and pets may be allowed to stay with the patient. Hospice care assists the family in crisis and continues for up to 1 year after the patient dies, with follow-up counseling, listening, nurturing, and referrals.

Outpatient care is given in the home with family members providing the primary care. Support care is given by the hospice staff. Medications and supplies are furnished by the hospice service. At home, the patient can enjoy loved ones, pets, plants, music, and personal surroundings for as long as possible. See Chapter 17, “Nursing Care of Patients at the End of Life,” for more information.

ONCOLOGICAL EMERGENCIES

Superior Vena Cava Syndrome

Superior vena cava syndrome (SVCS) occurs in patients with lung cancer or cancers of the mediastinum when the tumor or enlarged lymph nodes block circulation in the vena cava. This results in edema of the head, neck, and arms. Symptoms include shortness of breath, cough, chest pain, facial redness, and swollen neck veins. Radiation therapy can be used to shrink the tumor and allow circulation to resume naturally. Nursing interventions for the patient with SVCS include removing rings and restrictive clothing, avoiding taking blood pressure and venipunctures in the arms, and elevating the head of the bed to decrease feeling of dyspnea.

Spinal Cord Compression

Spinal cord compression occurs when a malignant growth presses on the spinal cord. This is a painful problem and requires pain management while radiation is given to relieve the symptoms. Patients may develop some motor loss when this occurs. Commonly, a myelogram or bone scan is used for diagnosis. Nursing care includes providing a safe environment, assisting with activity, and watching for changes in neurologic status as well as changes in the location or intensity of pain. Patients at risk include those with cancers that spread to the bone and spinal cord, such as lung, breast, and prostate cancer.

Hypercalcemia

In hypercalcemia, the serum calcium level exceeds 11 mg/dL. Hypercalcemia may result from the release of calcium into the blood from bone deterioration or from ectopic secretion of parathyroid hormone by a tumor. It is common in patients with bone metastasis, especially metastasis from breast cancer. It can be treated with IV medication and hydration to lower the calcium level. Nursing care includes maintaining safety and monitoring intake and output, pain control, and changes in pulse rate and rhythm.

SUGGESTED ANSWERS TO CRITICAL THINKING

Mrs. Jones

1. Mrs. Jones’s tumor is beginning to invade surrounding tissue. There is no lymph node involvement and no metastasis.
2. Doxorubicin is commonly associated with red urine and also poses a risk for cardiac toxicity. Cyclophosphamide can cause blood in the urine and a risk for hemorrhagic cystitis. Therefore, the patient should take in plenty of fluids and void often (every 2 hours). Both medications can cause nausea, vomiting, and alopecia. Both are vesicants.
3. Because the drugs are vesicants, it is important to inject them into a large vein.
4. Many diagnoses are appropriate, including Acute Pain related to surgical incision, Disturbed Body Image related to alopecia and loss of a breast, Imbalanced Nutrition: Less Than Body Requirements related to nausea and vomiting, Risk for Injury related to medication side effects, and Deficient Knowledge about cancer treatment and management of side effects. A thorough nursing assessment is needed to determine actual diagnoses.

REVIEW QUESTIONS

1. A patient asks, “How do malignant tumors differ from benign tumors?” Which of the following statements by the nurse are correct? Select all that apply.
   1. “Malignant tumors invade surrounding cells and tissues.”
   2. “Malignant tumors are generally encapsulated.”
   3. “Malignant tumors remain localized.”
   4. “Cells in malignant tumors stop dividing prematurely.”
   5. “Cells in malignant tumors lack contact inhibition.”
   6. “Malignant tumors have defective cell communication.”

2. A patient has received vinorelbine on day 1 of treatment. The nadir will occur in about 10 days. For which complication should the nurse be vigilant around Day 10?
   1. Infection
   2. Hair loss
   3. Diarrhea
   4. Myalgia
3. A female patient is starting on doxorubicin. Which of the following nursing interventions will be most helpful as she plans for hair loss?
   1. Obtain a prescription for a hair growth product.
   2. Massage her scalp to increase circulation and delay hair loss.
   3. Teach her to apply ice to her scalp to prevent hair loss.
   4. Help her choose a wig before her hair loss begins.

4. Which of the following nursing actions will best help the patient with cancer to control pain?
   1. Assess the patient’s anxiety level.
   2. Assess the patient’s understanding of the side effects of pain medication.
   3. Encourage the patient to use nonpharmacological methods for pain.
   4. Teach the use of a relaxation exercise to be used with prescribed analgesics.

5. The nurse notes that a patient undergoing treatment for bone cancer is having trouble walking. For which oncological emergency should the patient be assessed?
   1. Tumor lysis syndrome
   2. Hypercalcemia
   3. Spinal cord compression
   4. Thrombocytopenia

6. A nurse is intervening for a patient receiving radiation therapy with reddened skin over the treated area. How will the nurse know if nursing interventions have been effective?
   1. The patient will be able to describe a proper skin care regimen.
   2. The nurse will keep the skin clean and dry.
   3. The patient’s skin will remain intact without breakdown or infection.
   4. The nurse will report the reddened area to the physician.

7. Which of the following patients will benefit from hospice care?
   1. A patient who has liver cancer and is expected to live 4 to 6 weeks
   2. A patient who is having multiple side effects from aggressive chemotherapy
   3. A patient who is trying to make a decision about cancer treatment
   4. A patient with uncontrolled pain related to cancer and radiation treatment

8. A patient is receiving internal radiation therapy for a gynecological malignancy. The patient expresses feelings of isolation in her private room. What intervention would be best on the part of the nurse?
   1. Encourage the patient’s significant other to stay overnight.
   2. Move the patient into a semiprivate room so she can have a roommate.
   3. Instruct the patient about the safety procedures for internal radiation therapy.
   4. Plan to spend more time with the patient.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Describe factors that influence surgical outcomes.
2. Identify the LPN/LVN role in each perioperative phase.
3. Explain the LPN/LVN role in obtaining informed patient consent.
4. Develop a teaching plan to enhance learning for the older preoperative patient.
5. Identify nursing interventions used for common postoperative patient needs.
6. Describe how to evaluate effectiveness of nursing interventions.
7. List signs and symptoms of common postoperative complications.
8. List the criteria for ambulatory discharge.
9. Describe the role of the home health nurse in caring for postoperative patients.
Surgery is the use of instruments during an operation to treat injuries, diseases, and deformities. Surgical procedures are named according to (1) the involved body organ, part, or location and (2) the suffix that describes what is done during the procedure (Table 12.1). Physicians who perform surgery include surgeons or other physicians trained to do certain surgical procedures. Surgery is scheduled based on the urgency required for a successful outcome for the patient (Table 12.2). The reasons for surgery to be performed are listed in Table 12.2.

### Types of Surgery

Laser, scope, and robotic technologies reduce the invasiveness of surgical procedures. Minimally invasive surgery is less damaging to tissues than traditional open incision surgery. This allows a faster and less painful recovery. Laser surgery uses a laser instead of a scalpel to cut tissue. It is often used for eye surgery. An endoscope is used for minimally invasive surgery, also called keyhole surgery. Minimally

Continued
invasive surgery includes laparoscopic surgery (abdominal and pelvic cavity) and thoracoscopic surgery (chest and thoracic cavity). The endoscope is a flexible tube with a light, camera, and suction attached. It is inserted through a small incision and projects an image on a screen for the surgeon to watch. Additional incisions are made for other instruments depending on the type of surgery.

Robotic surgery, which uses robots, includes minimally invasive surgery. The da Vinci is one type of surgical robot with three or four arms. One is a camera, two are robotic arms that act as the surgeon’s hands, and the fourth arm moves obstructions out of the way (Fig. 12.1). As the surgeon moves his or her hands, the robotic arms (which are inside the patient’s body) mimic the movements by cutting, suctioning, or suturing. Visit www.intuitivesurgical.com for more information and videos.

### PHASES OF SURGERY

There are three phases in the surgical process: preoperative, intraoperative, and postoperative. These phases together are referred to as perioperative, which is the time before, during, and after surgery. Each of the perioperative surgical phases has a defined time frame in which specific events related to surgery occur (Table 12.3).
Your primary role as a licensed practical nurse/licensed vocational nurse (LPN/LVN) in the preoperative phase is to:

- Assist in data collection for developing the patient’s plan of care.
- Reinforce explanations and instructions given to the patient and family by the surgeon and registered nurse (RN).
- Provide emotional and psychological support for patients and their families.

You can help reduce family members’ anxiety by providing explanations so that they are less anxious and able to assist the patient during recovery.

Other health team members assist in preparing the patient for surgery. The surgeon obtains a medical history, performs a physical examination, and orders diagnostic testing. RNs perform a baseline preoperative assessment, provide explanations and instructions, offer patients and families emotional and psychological support to ease anxiety, develop a plan of care, and then verify the patient’s name, surgical site (along with the patient), allergies, and related information when the patient arrives in the surgical area.

Factors Influencing Surgical Outcomes

When preparing a patient for surgery and assisting in the development of a nursing care plan, the goal is to identify and implement actions that reduce surgical risk factors. Preoperative care focuses on helping the patient achieve the best possible surgical outcome by being in the healthiest possible condition for surgery.

Emotional Responses

The word surgery causes a common anxious emotional reaction in patients and their families. You need to be aware of these reactions to assist the patient in coping with them. If any of the patient’s fears are extreme, such as a fear of dying or not waking up after surgery, the surgeon should be informed.

Surgical patients may experience various fears related to anesthesia (reversible loss of sensation): possible brain damage, feeling sensation during surgery, feeling loss of control, or a fear of not waking up. The patient should discuss these concerns with the anesthesia professional. Listening to music or using guided imagery before surgery may reduce a patient’s anxiety (see “Evidence-Based Practice”).

It is normal for patients to be concerned about pain. During surgery, the anesthesia provider gives medications to control pain. Nurses give prescribed analgesics for pain relief after surgery. Complementary techniques can also be used to help reduce pain, such as guided imagery or focused breathing.

Changes in body image may be a great fear for some patients. The thought of disfigurement, mutilation, bleeding, or having a scar causes great anxiety for some patients. Allow them to discuss these fears.

### EVIDENCE-BASED PRACTICE

**Clinical Question**

Does listening to music reduce preoperative anxiety for surgical patients?

**Evidence**

Twenty-six studies comparing music listening with standard care preoperatively (Bradt, Dileo, & Shim, 2013). Music listening was found to have a beneficial effect on preoperative anxiety. Music even reduced anxiety more effectively than a sedative in one study.

**Implications for Nursing Practice**

Patients can be informed to bring in favorite music to listen to before surgery to reduce anxiety.

**REFERENCE**

### Age

Surgery can be a positive experience that promotes quality of life for many older patients. For healthy older patients, age alone does not mean that they are at greater surgical risk. Complications can occur, however, related to previous health status, immobilization occurring from surgery, normal aging changes reducing the effectiveness of deep breathing and coughing, and the effects of administered medications (see “Gerontological Issues”). Older patients may need a longer time to recover from anesthetic agents because of changes in drug metabolism and elimination related to aging.
Gerontological Issues

Surgical Considerations for the Older Adult

Older adults usually have limited physiological reserve, resulting in decreased ability to compensate for changes that occur during surgery. The risk for hemorrhage, anemia, fluid/electrolyte imbalance, and infection are increased in older adults. Increased risk for complications is secondary to age-related loss of blood vessel elasticity and decreased cardiac, respiratory, and renal reserves. Nursing interventions should be aimed at these age-related changes before, during, and after the surgical procedure to help reduce complications.

Preoperatively
- Reassure the patient and family.
- Pad bony prominences to protect against pressure ulcers and muscle and bone discomfort.
- Teach what to expect before, during, and after surgery; diet changes; description and length of surgical procedure; activities in the recovery room; pain management; coughing and deep breathing exercises; procedures; and treatments (e.g., dressings, catheters).
- Ensure preoperative screening: blood work, radiographic studies, nutritional assessments, pulmonary function tests, electrocardiogram (ECG).

Intraoperatively
- Assess patient for hypothermia
- Assess patient for hypoxia (older adult may exhibit restlessness).
- Assess patient for hemorrhage.
- Assess patient’s output (urine, drainage, bleeding, emesis).

Postoperatively

Pain Control—Provide adequate pain relief so required postoperative activities, such as deep breathing, coughing, position changes, and exercise, can be performed more effectively.

Respiratory Function—Reduce respiratory complications by encouraging deep breathing and coughing:
- Perform after pain medication has begun to take effect to encourage deep breaths due to less pain. Assess the patient carefully when giving narcotics because they can cause respiratory depression.
- Use a pillow and instruct the patient to hold it firmly over abdominal or chest incisions to support the incision. Taking a deep breath increases chest expansion, as well as abdominal pressure, which may pull or stretch an incision.
- Older adults perform deep-breathing and coughing exercises better if the nurse performs the exercises with them. For example, say the following: “Let’s take a deep breath in through the nose, hold it and count to three, then slowly blow it out completely through the mouth. When you blow the air out, shape your lips like they are going to whistle. Great, let’s do it again.”

Mobility—Encourage mobility through the following nursing actions and observations:
- Use pillows to support the patient’s body alignment; assist the patient to ambulate as soon as possible after surgery; and regularly help the patient with passive or active range-of-motion exercises, along with flexion and extension exercises, for legs and feet.
- Monitor for unilateral swelling of the leg and calf or groin pain, which may indicate deep venous thrombosis (DVT), a risk related to venous pooling in the lower extremities. This risk is increased with postoperative inactivity.
- Assist the patient to change position at least every 2 hours. If patients lay in one position too long, pressure ulcers can develop. When tissues are compressed between bones and the bed surface, blood supply is reduced to the tissue and cells begin to die. This results in painful open wounds.

Bowel Function—Assess bowel sounds. It is common for patients to feel bloated after surgery. Increasing activity, such as walking—not just sitting in a chair—stimulates peristaltic action of the bowel. This helps expel flatus and reduce discomfort.

Urinary Function—Be aware of the following aspects of urinary function:
- Individuals often have difficulty emptying their bladder after surgery. Patients who are sleeping but restless should be evaluated for bladder distention. It is often difficult to void on a bedpan or in a urinal in a supine position.
- Older men with an enlarged prostate may have even greater difficulty voiding if they have received medications that have urinary retention side effects.
- Assisting patients to sit or stand to use urinals, use a bedside commode, or ambulate to the bathroom promotes bladder emptying and helps avoid the use of urinary catheters.
- Measure urine output that is voided or from a catheter. Note the color and odor of the urine. Older adults are prone to dehydration, and this provides an indication of their hydration status for intervention.

Delirium—Perform the following nursing actions to minimize delirium:
- Monitor level of consciousness routinely. Provide a calm environment and orient patients to their environment. Restraints should not be used because they can worsen delirium.
- Recognize that the presence of a urinary catheter can contribute to delirium, so methods to avoid the need for a catheter should be tried.
Nutrition

Patients should be well nourished to adequately heal and recover from surgery (“Nutrition Notes”). Higher levels of protein (tissue repair and healing), vitamin C (collagen formation), and zinc (tissue growth, skin integrity, and cell-mediated immunity) are required. Patients who are obese or underweight may not heal as well and may have complications. Patients who are obese have more respiratory problems and wound healing difficulties, such as delayed healing and wound dehiscence (opening of the incision). Patients who are emaciated may have more infections and delayed wound healing because they lack the nutrients needed for tissue healing.

Smoking and Alcohol

Tobacco and alcohol use increases the surgical patient’s risks. Smoking thickens and increases the amount of lung secretions and reduces the action of cilia that remove the secretions. Patients should be encouraged to avoid smoking for at least 24 hours before surgery or 3 to 4 weeks before surgery if they have a chronic lung disorder. Not smoking increases the action of the lungs’ defense mechanisms and makes more hemoglobin available to carry oxygen during surgery. It also improves wound healing.

Long-term alcohol use may cause nutritional deficiencies and liver damage, which can create bleeding problems, fluid volume imbalances, and drug metabolism alterations. In addition, alcohol interacts with medications and should be avoided before surgery.

Chronic Disease

Chronic disorders may increase the patient’s surgical risk unless they are well controlled. A medical clearance for surgery may be needed from the patient’s health care practitioner (HCP).

Preadmission Surgical Patient Assessment

Nonemergent surgical patients have either an interview with the anesthesiologist or a preadmission telephone or face-to-face interview with RNs in the preadmission testing department under the direction of the anesthesia professional. The interview process includes a health history, identification of risk factors, patient and family teaching, discharge planning, and necessary referrals to social work, support groups, and educational programs. Patients are asked if there have been any personal or family problems with anesthesia or malignant hyperthermia. Malignant hyperthermia is a rare hereditary muscle disease that can predispose the patient to a serious life-threatening reaction to certain anesthetic agents (discussed later).

Preoperative diagnostic testing is based on the patient’s age, medical history, assessment findings, and institutional protocols (see Table 12.4). A urine or serum pregnancy test as appropriate for female patients may be done to prevent fetal exposure to anesthetics. Health information and diagnostic testing results are reviewed by anesthesia providers. Abnormal test results are reported to the surgeon. Interventions are ordered for abnormalities.

Continued
Federal law says patients must be asked before surgery if they have a signed advance directive (e.g., health care durable power of attorney or living will) for their medical record (see Chapter 17). If there is no advance directive, written information on advance directives is offered.

**Preoperative Teaching**

**Preoperative Routines**

Preoperative teaching provides information about common surgical preparation procedures and routines:

- Date and time of admission and surgery
- Admission procedures, including arriving about 2 hours before surgery to allow preparation time
- Length of stay, items to bring and wear
- Recovery after surgery
- Family information, such as where to wait during surgery and who communicates patient’s status to them
- Discharge criteria, including the need for a responsible adult to take the patient home after outpatient surgery.

**Preoperative Instructions**

To reduce the risks of pulmonary aspiration during surgery, the anesthesia professional orders fluid and food restrictions. The minimal fasting time frame guidelines of the American Society of Anesthesiologists are listed in the “Nutrition Notes.” Patients may brush their teeth or rinse their mouth without swallowing. Cancellation of surgery can result if the patient has not followed instructions to stop eating or drinking as specified.

Medications the patient is to take the morning of surgery, with an ounce of water, are explained. Special preparations, such as an enema, are also described. For abdominal or intestinal surgery, enemas are ordered to empty the bowel to reduce fecal contamination preoperatively and straining or distention postoperatively.

Instructions for postoperative care are given before surgery so the patient is alert when being taught and has time to learn. Patients should be told that active participation in postoperative care aids in their recovery. Teach patients how to report their pain level using a pain rating scale so that prompt pain relief can be provided (see Chapter 10). Pain rating scales include a 0 (none) to 10 (worst possible) rating scale, a color-based rating scale, or a scale using pictures of faces showing varying degrees of frowning or smiling that indicate a certain pain level. Pain relief methods are described, such as analgesic injections, an epidural catheter, or patient-controlled analgesia (PCA). Anticipated dressings, tubes, casts, or special equipment are also described. If needed, crutches are fitted to the patient, and their proper use is explained and demonstrated.

Postoperative exercises are taught to decrease complications. They include deep breathing and coughing, use of incentive spirometry, leg exercises, turning, and how to get out of bed. After an exercise is taught, the patient should perform a return demonstration so understanding and ability to perform the exercise correctly can be evaluated.

Deep breathing helps prevent the development of **atelectasis** (collapse of the lung caused by hypoventilation or mucous obstruction preventing some alveoli from opening and being fully ventilated) by expanding and ventilating the lungs. The patient is taught to sit up, exhale fully, take in a

**atelectasis:** atele—imperfect + ektasis—expansion
deep breath through the nose, hold the breath and count to three, and then exhale completely through the mouth. The patient is told to repeat this hourly while awake, in sets of five, for 24 to 48 hours postoperatively.

Incentive spirometry can also be ordered postoperatively to prevent atelectasis by increasing lung volume, alveoli expansion, and venous return (Fig. 12.2). All patients can benefit from incentive spirometry, especially the older adult and those at increased risk for lung complications. The spirometer stays at the patient’s bedside for hourly use while awake (not on the window sill or in a drawer where it cannot be reached by the patient!). Offer the spirometer to the patient each hour to ensure that it is used. Teach patients to do the following:

- Sit upright, at 45° minimum, if possible.
- Take two normal breaths. Place mouthpiece of spirometer in mouth.
- Inhale until target, designated by spirometer light or rising ball, is reached, and hold breath for 3 to 5 seconds.
- Exhale completely.
- Perform 10 sets of breaths each hour.

Coughing moves secretions to prevent pneumonia. Teach patients how to cough effectively if not contraindicated by the patient’s condition (such as hernia repair or head injury; Table 12.5). Give pain medication before asking the patient to cough and offer reassurance that coughing should not harm the incision. Splinting the incision with a pillow may be comforting. Several sets of coughing are performed every 1 to 2 hours while the patient is awake.

Leg exercises and foot circles done every hour while awake, if not contraindicated, improve circulation and help prevent complications related to stasis of blood, such as emboli formation. Teach patients to do the following:

- Lie down, raise leg, and bend leg at the knee.
- Flex foot, extend leg, and lower it to the bed.
- Do sets of five for each leg.
- For foot circles, raise a leg slightly off the bed with toes pointed.
- Draw a circle in the air with the great toe.
- Rotating to the right four times, then to the left four times.
- Repeat this five times and then repeat with the other foot.

Patients are taught that turning from side to side in bed is aided by bending the leg that is to be on top and placing a pillow between the legs to support the top leg. Unless contraindicated, have patients use the bed’s side rail to pull themselves over to the side. To promote comfort, patients are encouraged to deep breathe while turning instead of holding their breath.

To make it easier for patients to get out of bed and to reduce strain on the incision, instruct patient to do this:

- Turn on side without pillows between knees.
- Place hands flat against the bed.
- Push up while swinging legs out of bed into a sitting position.

**TABLE 12.5 TEACHING PATIENTS COUGHING TECHNIQUES**

<table>

<tr>
<th>Procedure</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Have patient sit up and lean forward.</td>
<td>Promotes lung expansion and ability to generate forceful cough.</td>
</tr>
<tr>
<td>Show patient how to splint incision with hands, pillow, or blanket.</td>
<td>Reduces incision pressure so it does not feel as if incision is opening.</td>
</tr>
<tr>
<td>Have patient inhale and exhale deeply three times through mouth.</td>
<td>Helps expand lungs.</td>
</tr>
<tr>
<td>Have patient take in deep breath and cough out the breath forcefully with three short coughs using diaphragmatic muscles.</td>
<td>Generates forceful cough and expands lungs to help move secretions.</td>
</tr>
<tr>
<td>Take in quick deep breath through mouth, cough deeply, and deep breathe.</td>
<td></td>
</tr>
</tbody>
</table>
UNIT TWO  Understanding Health and Illness

• Sit for a few minutes after changing position to avoid dizziness and falling.
• Deep breathe while sitting to expand lungs.

Nursing Process for Preoperative Patients

Data Collection

HEALTH HISTORY. Upon admission for surgery, patient data are collected (Table 12.6). Ensure that patients use their contact lenses, glasses, or hearing aids for accurate communication. Note the patient’s emotional reaction to surgery. If the patient is anxious, explore the cause of the anxiety and allow the patient to express concerns. Anxiety is a feeling of apprehension or uneasiness resulting from the uncertainties and risks associated with surgery, whereas fear, a feeling of dread from a source known to the patient, is an extreme reaction to surgery.

Medications. All prescription and over-the-counter medications that the patient takes are reviewed, along with any herbal remedies or recreational drugs. Anticoagulants such as warfarin (Coumadin), or nonsteroidal anti-inflammatory drugs (NSAIDS) including aspirin may need to be stopped several days before surgery to avoid bleeding problems during surgery. Because herbal medicines can interfere with medications used during surgery or increase bleeding times, patients may be instructed to stop them 1 to 2 weeks before surgery.

Physical Assessment

Vital signs, oxygen saturation

Height and weight

Emotional status Calm, anxious, tearful

Neurologic Ability to follow instructions

Skin Color, warmth, bruises, lesions, turgor, dryness, mucous membranes

Respiratory Infection (cough; breath sounds); chronic obstructive pulmonary disease; respiratory rate, pattern, and effort; barrel chest

Cardiovascular Angina, myocardial infarction, heart failure, hypertension, valvular heart disease, mitral valve prolapse, heart rate and rhythm, peripheral pulses, edema, jugular vein distention

Gastrointestinal Bowel sounds, date of last bowel movement, abdominal distention, firmness, ostomy

Musculoskeletal Deformities, weakness, decreased range of motion, crepitation, gait, artificial limbs, prostheses
Patients with diabetes who take insulin are usually instructed by anesthesia either to hold their insulin or to take half of their normal dose of insulin the day of surgery. On the day of surgery, blood glucose monitoring is done every 4 hours or as ordered to ensure that blood glucose levels are maintained within a desired range.

Patients on chronic oral steroid therapy cannot abruptly stop steroids even though they may be NPO (nothing by mouth) before or after surgery. Serious complications, such as circulatory collapse, can develop if steroids are stopped abruptly. The physician should order a patient’s steroid therapy to be given by a parenteral route if the patient is NPO, so that it is not interrupted. Make sure that the steroid therapy is ordered and continued for the patient.

Patients should be asked about the use of alcohol or drugs such as cocaine, marijuana, or opioids because the y can interact with anesthesia or other medications. To obtain honest, accurate information, patients should be told of this potential interaction. Information and questions should be stated in a nonjudgmental manner. For example, you should ask, “How much alcohol do you drink daily or weekly?” instead of “Do you drink alcohol?” The first statement assumes that people drink alcohol. This allows the patient who does not drink to indicate none and the patient who does to state an amount rather than having to say yes and then give an amount upon further questioning. More accurate responses are given because this approach is viewed more positively by the patient who consumes alcohol. Another example would be to ask the patient, “What roles do drugs or alcohol play in your life?”

Physical Assessment
A physical assessment of body systems is performed. This information can highlight risk factors for surgery, determine the type of anesthesia to be used, and assist in planning interventions to reduce risk factors. A cough, cold, or fever is reported to the surgeon because surgery may be delayed until the patient recovers from an acute infection. Dentures, bridges, capped teeth, and loose teeth are documented because they can become dislodged during intubation (insertion of endotracheal breathing tube) for general anesthesia, causing complications.

Nursing Diagnoses, Planning, and Interventions

Deficient Knowledge related to lack of previous experience with surgical routines and procedures

**Expected Outcome:** Patient will demonstrate understanding of surgical information and routines before surgery.

- Patient anxiety levels should be considered when providing explanations because learning can be affected by high anxiety levels.
- Identify knowledge deficiencies with the patient so that he or she is motivated to learn.
- Reinforce information provided before admission and new information to patients to promote informed choice and increase self-care abilities. Teaching is caring in action and empowers patients to be a participant in their care.
- Include the patient’s family or caregivers in teaching sessions so they can assist the patient through the surgical experience.
- Use a variety of teaching methods (discussion, written materials and instructions, models, and videos) to allow for different learning styles and to reinforce learning.
- Individualize explanations so the patient is not overwhelmed.
- Use teaching methods that can be adapted to aging changes that may affect learning. “Gerontological Issues” describes methods to provide a positive learning experience for the older patient.
- Document teaching and patient understanding. Documentation is essential as proof of what was explained and patient understanding.

**Gerontological Issues**

**Considerations for Older Patient Teaching Sessions**

**Environmental Considerations**
- Comfortable: anxiety free, quiet, appropriate temperature
- Correctly lit: small, intense lighting with nonglare, soft white light (not fluorescent)
- Private: no distractions, no background noise, turn off pagers

**Presentation Considerations**
- Assess readiness to learn.
- Assess comfort and safety needs.
- Use past experience and relate to new learning.
- Base learning on assessment data and current knowledge base.
- Use simple, understandable words and avoid medical jargon.
- Use legible audiovisual materials: large print, black print on white nonglare paper.
- If using colors, remember that older adults see red, orange, and yellow best; blue, violet, and green are more difficult to see.
Evaluation

The goal of decreased anxiety is achieved if the patient states and demonstrates that anxiety is relieved. If the patient is able to learn during teaching sessions, anxiety is not a barrier to learning. The goal for correcting deficient knowledge is reached if the patient states understanding of the information presented and accurately performs return demonstrations of presented information.

Preoperative Consent

Before performing surgery, it is the surgeon’s responsibility to obtain voluntary, written, informed consent from the patient. The consent gives legal permission for the surgery and has two purposes: It protects the patient from unauthorized procedures, and it protects the surgeon, anesthesia professional, hospital, and hospital employees from claims of performance of unauthorized procedures. A signed consent is needed for all invasive procedures, surgery, anesthesia, blood administration, and radiation or cobalt therapy. It is typically valid for 30 days after signing.

Informed consent involves three elements:

1. The surgeon must explain in terms the patient understands about the diagnosis, the proposed treatment and who will perform it, the likely outcome, possible risks and complications of treatment, alternative treatments, and the prognosis without treatment. If the patient has questions before signing the consent, the surgeon must be contacted to provide further explanation to the patient. It is not within the nurse’s scope of practice to provide this information.
2. The consent must be signed before analgesics or sedatives are given because patients must demonstrate to the witness that they are informed and understand the surgery.
3. Consent must be given voluntarily. No persuasion or threats can be used to influence the patient. The patient can withdraw consent at any time, even after the consent form has been signed.

To ensure that patients are truly informed before signing a consent form, in some institutions, patients must take and pass a knowledge quiz, which can be given verbally. If they do not pass the quiz, further explanation is needed by the surgeon. Also, in the surgical holding area, patients verbally reconsent. They are asked, “Do you still remember what you were told about your surgery?”

It is often your role to obtain and witness the patient’s or authorized person’s signature on the consent form (Fig. 12.3). As the patient’s advocate, you must ensure that the person signing the consent form understands its meaning and has no further questions to be directed to the HCP before it is signed and that it is being signed voluntarily. If the patient is unable to read, the entire consent must be read to the patient before it is signed. Patients are unable to give consent if they are unconscious, are mentally incompetent, are minors, or have received analgesics or drugs that alter central nervous system function within time frames specified by agency policy. Consent may be obtained in any of these cases from parents, next of kin, or legal guardians as specified by law.
NURSING CARE TIP

Witnessing a Consent
Your signature as a witness on a consent form indicates that you observed the informed patient or patient’s authorized representative voluntarily sign the consent form. It does not mean that you informed the patient about the surgical procedure; that is the responsibility of the HCP.

In a medical emergency, the patient may not be able to give consent. In this case, the next of kin or legal guardian may give telephone consent, or a court order can be obtained. If time does not permit this, the surgeon documents the need for treatment in the chart as necessary to save the patient’s life or avoid serious harm, according to state law and institutional policy.

Preparation for Surgery

Preoperative Preparation Checklist
A preoperative checklist is usually completed and signed by the nurse (per agency policy) before the patient is transported from the surgical unit to surgery (Fig. 12.4). The checklist provides guidance for preoperative preparation of the patient:

• An identification band is placed on the patient. A hospital gown is given to the patient to wear. Underwear is removed, depending on the type of surgery.
• Vital signs are taken and recorded as baseline information and to assess patient status.
• Makeup, nail polish, and artificial nails (if applicable) are removed to allow assessment of natural color and pulse oximetry for oxygenation status during surgery.
• Removal of hairpins, wigs, and jewelry prevents loss or injury. Rings, such as wedding rings, are taped in place if the patient does not want to take them off, except if the ring is on the operative side (arm or chest surgery), because edema may occur.
• Dentures, contact lenses, and prostheses are removed to prevent injury. Some patients are concerned about body image and do not want family members to see them without dentures or makeup. Remove dentures after the family goes to the waiting room and insert them before the family sees the patient postoperatively.
• Glasses and hearing aids go with patients to surgery if they are unable to communicate without them. Label them with the patient’s name and document where they go.
• All orders, diagnostic test results, consents, and history and physical (required on the chart) are reviewed for completion and documented on the checklist.
• Patient valuables are recorded and given to a family member or locked up per institutional policy by the nurse.

Preoperative Medications

Preoperative medications are given at the time ordered or on call to surgery (i.e., surgery calls to instruct that it is time to give the drugs; Table 12.7). If sedatives or analgesics are given, the bed rails are raised for safety and the patient is instructed not to get up alone.

BE SAFE!

National Surgical Care Improvement Project (SCIP)
Goal: Improve the safety of surgical care by reducing postoperative complications.

The Centers for Medicare and Medicaid Services, the Joint Commission, and other national organizations partnered for this quality project (www.jointcommission.org). Education for the public is provided in “Tips for Safer Surgery,” which summarizes project categories for reducing surgical complications. The information encourages patients to ask their HCP and nurses questions about their surgery. Being aware of this project will help you accurately answer your patients’ questions in providing safe surgical care.

Prevention: Areas covered by the SCIP include surgical site infections (SSIs), normothermia, venous thrombo event (VTE), and adverse cardiac events. Methods for preventing SSIs include the following:

• Giving prophylactic antibiotics within 1 hour before incision time and stopping them within 24 hours.
• Using electronic clippers for site hair removal, controlling perioperative serum glucose during major cardiac procedures, and removing urinary catheters by postoperative day 2.
• Maintaining core body temperature within normal range (normothermia) reduces risk (infection, impaired wound healing, MI, blood transfusion) in the perioperative period.
• VTE can be prevented by administering appropriate perioperative anticoagulants to those at risk.
• Avoiding adverse cardiac events includes giving beta blockers during the perioperative period to eligible major noncardiac surgical patients and to surgical patients who have coronary artery disease, and informing the HCP of all medications and herbs taken.

### Transfer to Surgery Department

When the surgery department is ready, the patient is transported to the surgical holding area on a gurney (Fig. 12.5). The patient’s chart, inhaler medications for those with asthma, and glasses or hearing aids to aid communication are taken with the patient. Family members can accompany the patient. During the surgery, the family waits in the surgical waiting area, which is a communication center where the family can be called via cell phone or given a beeper to be kept informed of the patient’s status.

### Post-Transfer to Surgery Department

After the patient goes to the surgery department, you can prepare the patient’s room and necessary equipment so it is ready upon the patient’s return (Table 12.8).

### Patient Arrival in Surgery Department

The holding area nurse greets the patient; verifies the patient’s name, age, allergies, surgeon performing the surgery, informed consent, surgical procedure (right site, especially right

or left when applicable), and medical history; answers questions; and alleviates anxiety. The patient is introduced to the anesthesiologist and certified registered nurse anesthetist (CRNA), who also verify patient information and explain the type of anesthesia that is to be used. All surgical patients have IV fluids started. The patient may also receive prophylactic antibiotics.

Before entering the operating room (OR), the patient should be told what to expect:
- “If the room feels cool, you can request extra blankets.”
- “There is a lot of equipment in the room, including a table and large, bright overhead lights.”
- “Several health care team members will introduce themselves to you.”
- “Your surgeon will greet you.”
- “A safety checklist will be performed.”

**Preoperative Warming**

To maintain normal body temperature (normothermia) and reduce intraoperative hypothermia, which is associated with complications, prewarming peripheral tissues or surface skin before anesthesia is helpful. Use of forced-air warming devices for 30 minutes may reduce hypothermia. Patients should be normothermic before transfer to surgery.

**INTRAOPERATIVE PHASE**

When the patient is transferred to the operating table, the next phase of the perioperative period, the intraoperative phase, begins. Surgery may take place in a hospital OR or

worn. If nail polish is worn, it should not be chipped and should be removed and reapplied every 4 days. Sterile gloves are then worn by the surgical team to keep the surgical field sterile.

The OR is designed to enhance aseptic (elimination of microorganisms) technique. Clean and contaminated areas are freestanding ambulatory or outpatient surgical center (Figs. 12.6 and 12.7). Additionally, surgery is performed in physician’s offices, cardiac catheterization laboratories, radiology centers, emergency rooms, and specialized units that perform endoscopy procedures.

The OR team members (Box 12-1) must perform a sterile surgical hand scrub to reduce the amount of microorganisms on their hands and arms. Jewelry (e.g., watches, rings, bracelets) is also removed. Fingernails are kept short and clean. Artificial nails and nail polish may harbor microorganisms and therefore are recommended not to be worn.

**Box 12-1 Surgical Health Care Team Members and Roles**

Members of the surgical health care team and their roles are as follows:

- **Surgeon** (medical doctor, doctor of osteopathy, oral surgeon, or podiatrist)
- **Surgical (first) assistant**: assists the surgeon and is another physician, a specially trained RN, or a physician’s assistant
- **Anesthesiologist**: physician who specializes in administering anesthesia and supervises certified registered nurse anesthetists (CRNAs) in the operating room
- **CRNA**: an RN trained and certified in administering anesthesia, usually at the master’s degree level
- **RN**: circulates in the OR; roles include being patient’s advocate, planning care, protecting patient safety, monitoring patient positioning, checking vital signs and patient assessment, reducing patient’s anxiety, monitoring sterility during surgery, preparing skin before incision, managing equipment such as by making sponge counts, documenting the procedure, and aiding health team communications
- **Surgical (second assistant) technician**: assists surgeon (may be an RN, LPN/LVN, or surgical technologist)
Because of the potential for microabrasions and colonization should be removed with electric clippers. Shaving is avoided rechecked. If the patient requires body hair removal, hair inserted by the RN.

.. raw:: html

    ![Image](https://via.placeholder.com/150)

Place, such as a nasogastric (NG) tube or urinary catheter, are positioned to prevent pressure points that could cause tissue injury and nerve damage. Any needed tubes that are not already in position are developed from preadmission assessment data (Box 12-2).

The patient is assisted onto the operating table, and a safety strap is carefully applied. A time-out is taken. Then monitoring equipment is applied and readings recorded. The anesthesia provider begins administering anesthesia. When the anesthesia provider gives permission, the patient is carefully anesthetized.

Attention is given to the safety needs of the patient. A surgical case cart containing sterile instruments required for the patient’s case is prepared ahead of time.

Patient allergies, including skin prep solutions, are rechecked. If the patient requires body hair removal, hair should be removed with electric clippers. Shaving is avoided because of the potential for microabrasions and colonization by microorganisms. Then a skin prepping solution such as povidone-iodine is used to cleanse the skin. A large area surrounding the operative site is scrubbed to allow for extension of the incision. The scrub is completed in a circular motion from inside to outer edge. If an allergic reaction to the solution occurs, it can cause skin redness and blistering wherever the solution was used. After the skin is scrubbed, a sterile drape is applied with the incisional area left exposed.

**Box 12-2 Intraoperative Nursing Diagnoses and Expected Outcome**

- **Risk for Injury** related to perioperative positioning, chemicals, electrical equipment, and effect of being anesthetized
  
  - Is free from injury.

- **Risk for Impaired Skin Integrity** related to chemicals, positioning, and immobility
  
  - Skin integrity is maintained.

- **Risk for Deficient Fluid Volume** related to NPO status and blood loss
  
  - Maintains blood pressure, pulse, and urine output within normal limits.

- **Risk for Infection** related to incision and invasive procedures
  
  - Is free of symptoms of infection.

- **Pain** related to positioning, incision, and surgical procedure
  
  - Reports pain is relieved to satisfactory level.

**Anesthesia**

Anesthesia is used during surgery to prevent pain and allow the procedure to be done safely. The type of anesthesia and the anesthetic agents are ordered by the anesthesia provider with input from the patient and surgeon.

There are two types of anesthesia: general and local (regional). General anesthesia causes the patient to lose sensation, consciousness, and reflexes. It acts directly on the central nervous system (Box 12-3). Local anesthesia blocks nerve impulses along the nerve where it is injected, resulting in the loss of sensation to a region of the body without the loss of consciousness.

**General Anesthesia**

General anesthesia is commonly given by IV or inhalation. It is chosen when patients are anxious or do not want local anesthesia, when the surgical procedure will take a long time and there is a need for muscle relaxation, or when the patient is unable to cooperate, as in head injury muscle disorders, or impaired cognitive function.

**INTRAVENOUS AGENTS.** To begin most general anesthesia, the patient is induced (which means “to cause anesthesia”) with a short-acting IV agent that provides a rapid, smooth induction (the period from when the anesthetic is first given until full anesthesia is reached). Because these agents last only a few minutes, they are used along with inhalation agents, which maintain anesthesia during surgery. After induction, the patient is intubated with an endotracheal (ET) tube to provide mechanical ventilation and anesthesia (Fig. 12.8).

**INHALATION AGENTS.** Maintenance of anesthesia is accomplished by using inhalation agents. These agents are delivered, controlled, and excreted through mechanical ventilation.

**BE SAFE!**

*Improve the safety of using medications. Label all medications, medication containers (e.g., syringes, medicine cups, basins), or other solutions on and off the sterile field in perioperative and other procedural settings (Joint Commission’s 2014 National Patient Safety Goals. © The Joint Commission, 2013. Reprinted with permission.)*
Box 12-3 Malignant Hyperthermia
Malignant hyperthermia is a rare hereditary muscular disease that can be triggered by some types of general anesthetic agents. A history of anesthetic problems in the patient or family members detects the potential for development of this condition so that precautions can be taken. A history of heat stroke increases the risk of malignant hyperthermia. A muscle biopsy diagnoses this problem. Patients with this condition can undergo surgery safely with careful planning and choice of anesthetic agents by the anesthesia provider.

In malignant hyperthermia, metabolism in the muscles is increased, which produces a very high fever and muscle rigidity, as well as tachycardia, tachypnea, hypertension, dysrhythmias, hyperkalemia, metabolic and respiratory acidosis, and cyanosis. Malignant hyperthermia is life threatening, so immediate treatment is required to prevent death. Surgery is stopped, and anesthesia discontinued immediately. Oxygen at 100% is given. The patient must be cooled with ice and infusions of iced solutions. Dantrolene sodium (Dantrium), a muscle relaxant that relieves the muscle spasms, is the most effective medication for malignant hyperthermia. Dantrolene sodium is kept readily available in the operating room and given according to the treatment protocol of the Malignant Hyperthermia Association of the United States (www.mhaus.org).

Inhalation agents and the ET tube can be irritating to the respiratory tract. Complications that can occur from their use include laryngospasm (sudden violent contraction of the vocal cords), laryngeal edema, irritated throat, or injury to the vocal cords. When the tube is removed, the nurse should closely monitor the patient and be prepared to provide respiratory support and assist with reintubation if complications arise.

ADJUNCT AGENTS. An adjunct agent is a medication used along with the primary anesthetic agents. These medications can include opioids to control pain, muscle relaxers to avoid movement of muscles during surgery, antiemetics to control nausea or vomiting, and sedatives to supplement anesthesia.

Local (Regional) Anesthesia
Local anesthesia is selected for the patient who is not anxious, can tolerate the local agent, and is not required by the surgical procedure to be unconscious or have relaxed muscles. It is a good choice for some outpatient procedures. The anesthesia provider, or sometimes the surgeon, administers local anesthesia.

In topical administration, the agent is placed directly on the surgical area. Local infiltration is achieved by injecting the medication into the tissue where the incision is to be made. A nerve block is the injection of a local agent into a nerve at a specific point. A Bier block is done by placing a tourniquet on an extremity to remove the blood and then injecting the local agent into the extremity. A field block is a series of injections surrounding the surgical area. Use of these blocks has risen.

SPINAL AND EPIDURAL BLOCKS. Injection of a local agent into the subarachnoid space produces spinal block (Fig. 12.9). Epidural block occurs when the local agent is injected into the epidural space. Spinal and epidural blocks are used mainly for lower extremity and lower abdominal surgery. Both motor and sensory function is blocked. The patient must be carefully monitored for complications. Hypotension results from sympathetic blockade causing vasodilation, which reduces venous return to the heart and therefore reduces cardiac output. Respiratory depression results if the block travels too far upward. As the block wears off, patients feel as if their legs are heavy and numb. This is normal, and reassurance should be offered to the patient that this type of feeling does not last after the block wears off.

Complications. A postdural puncture headache results from leakage of cerebrospinal fluid (CSF) from the needle puncture hole in the dura. This reduces pressure on the spinal cord and brain, causing a low-pressure headache, which can be severe. The use of less than 25-gauge spinal needles helps prevent headache. Nausea, dizziness, tinnitus, and vision disturbances may also be present. The headache can worsen when standing or sitting.

Conservative treatment is not usually effective. An autologous epidural blood patch can be used to block the CSF leakage. This sterile procedure is done by the anesthesiologist. To create an epidural blood patch, approximately 15 to 20 mL of the patient’s blood is injected into the epidural
space one interspace below the previous puncture site. Blood patch treatment can be repeated if needed.

**Procedural Sedation and Analgesia**

Procedural sedation and analgesia (formerly conscious sedation) is purposeful, minimal sedation that does not cause the complete loss of consciousness during selected painful or uncomfortable dental, diagnostic, or medical procedures. The patient may fall asleep but arouse easily and respond. Patients remain in control of their own airway, are comfortable and respond purposefully. Medications such as propofol, ketamine, midazolam, and opioids (fentanyl or morphine) are given to produce sedation. Selection of patients who are eligible for this sedation is based on the procedure, the patient's general health, and patient or physician preference. Examples of short procedures for which this type of sedation is used are dental procedures, endoscopy, cardioversion, and closed fracture reduction. Procedural sedation can be provided by anesthesia providers or ordered by a physician and given by a specially trained RN.

The patient does not eat for 6 hours before the procedure but may have clear liquids up to 2 hours before the procedure. A signed informed consent is obtained. Then an IV for medications and fluids is inserted before the procedure. Patient monitoring is done every 5 minutes to check vital signs, ECG, and oxygen saturation. Changes are reported to the physician. Oxygen may be given by nasal cannula or mask. Emergency equipment (e.g., airway suction, defibrillator, drugs) is on standby, according to advanced cardiac life support (ACLS) protocols.

After the procedure, the patient awakens easily and quickly but may remember little about the procedure. The patient is monitored about every 15 minutes for response to the procedure and medications until he or she is fully awake and stable. The patient is ready for discharge when vital signs return to baseline and are stable, oral fluids are retained, voiding has occurred (if applicable), and written and oral discharge teaching is given to both the patient and the responsible adult to whom the patient is being discharged. The responsible adult and the patient must sign the instructions. Instructions include the following: An adult must drive the patient home and provide a safe environment, and the patient must not and will not drive or operate heavy machinery or sign legal documents for 24 hours.

**Transfer From Surgery**

When surgery is completed and anesthesia stopped, the patient is stabilized for transfer. The patient is normothermic upon transfer from surgery. After local anesthesia, the patient may return directly to a nursing unit. After general and spinal anesthesia, the patient goes to the perianesthesia care unit (PACU) or, in some cases, an intensive care unit (ICU; Fig. 12.10).

**LEARNING TIP**

In comparison with general anesthesia, procedural sedation and analgesia:

- Is less invasive.
- Requires less medication.
- Causes less depression of the cardiovascular and respiratory systems.
- Allows the patient to more quickly return to a wakeful state.
Patient safety, which is always a priority, is an important concern at this time. The patient is never left alone. Ensuring a patent airway and preventing falls and injury from uncontrolled movements are priorities. The anesthesia provider and OR nurses transfer the patient to the PACU and monitor the patient until the perianesthesia nurse is able to receive the report and assume care of the patient to promote safe recovery from anesthesia. The family is updated on the patient’s status after surgery by the surgeon.

**BE SAFE!**

*Improve the effectiveness of communication among caregivers. Implement a standardized approach for “handing off” communications, including an opportunity to ask and respond to questions (Joint Commission’s 2014 National Patient Safety Goals. © The Joint Commission, 2013. Reprinted with permission.)*

**POSTOPERATIVE PHASE**

The postoperative phase, which is the final perioperative phase, begins when the patient is admitted to the PACU or a nursing unit and ends with the patient’s postoperative evaluation in the surgeon’s office.

**Admission to the Perianesthesia Care Unit**

When the patient is admitted to the PACU, an admission assessment is done. The priority areas of patient assessment are:

- Respiratory status and patency of airway
- Vital signs with temperature and SaO₂
- Exhaled end-tidal carbon dioxide (EtCO₂)
- Level of consciousness and responsiveness
- Surgical site incision/dressing/drainage tubes
- Pain level and pain management

Oxygen by nasal cannula or mask is given if the patient has had general anesthesia, or as ordered. Some patients who are still intubated may require mechanical ventilation. Continuous monitoring is done on all patients for ECG, vital signs, exhaled end-tidal carbon dioxide, and pulse oximetry. The surgical site incision or dressing is assessed. Drainage amount and color, and hematoma formation are documented and reported as needed. Tubes (urinary catheter, drains, NG) or other equipment are checked for function and patency as applicable.

The patient’s temperature is measured on admission to the PACU. If the patient’s temperature is normal, the temperature is monitored hourly and at discharge from PACU. Passive methods to maintain temperature are continued: room temperature at or above 75°F (24°C), head coverings, or warm liquids. If shivering due to hypothermia occurs, the temperature is retaken. For hypothermia, active warming usually with a forced-air warming system is used. Temperature is monitored every 15 minutes until normal. Patients are taught to stay warm with a warm room, blankets, layered clothing, head coverings, or warm liquids. The patient must be normothermic before PACU discharge.

The responsibilities of perianesthesia nurses are listed in Box 12-4. It is essential for nurses to perform hand hygiene between patients in the PACU. Vital signs and assessment are done at least every 5 to 15 minutes, IV fluid infusion is maintained, and IV or PCA analgesics are given for pain as needed. Antiemetics are administered for nausea or vomiting. Deep breathing and coughing, if not contraindicated by the surgical procedure (hernia repair; eye, ear, intracranial, and jaw surgery; and plastic surgery) are encouraged. If the patient is no longer NPO, ice chips or sips of water may be offered for a dry mouth when the patient is fully awake.

**Nursing Process for Postoperative Patients in PACU**

Postoperative complications may occur due to the surgical procedure, anesthesia, blood and fluid loss, immobility, unrelied pain, or other diseases the patient may have. Nursing care focuses on preventing, detecting, and caring for these complications.

**Respiratory Function**

**DATA COLLECTION.** Normal respiratory function can be altered in the immediate postoperative period by airway...
obstruction, hypoventilation, secretions, laryngospasm, or decreased swallowing and cough reflexes. Respiratory function assessment includes respiratory rate, depth, ease, and pattern. Breath sounds, chest symmetry, accessory muscle use, and sputum are also observed.

**Nursing Diagnoses, Planning, and Implementation**

**Ineffective Breathing Pattern related to anesthesia, pain, and analgesic/sedative medications**

**Expected Outcome:** Patient will maintain normal EtCO₂ and SaO₂ levels at all times.

- Maintain oxygen therapy as ordered to prevent hypoventilation, which can be an effect of anesthesia medications or analgesics, decreased level of consciousness, or an incision in the thorax causing painful respirations.
- Encourage deep breathing to expand the lungs.
- Give analgesics carefully to promote deep breathing but avoid respiratory depression.
- Maintain continuous positive airway pressure/bilevel positive airway pressure (CPAP/BiPap) to treat sleep apnea. (Patients may bring their CPAP/BiPap machines with them.)
- Report respiratory depression or abnormal EtCO₂ to the anesthesiologist to obtain prompt treatment.

**Ineffective Airway Clearance related to obstruction, anesthesia medications, and secretions**

**Expected Outcome:** Patient will have a patent airway at all times.

- Ensure that patient maintains a patent airway because airway obstruction may result when relaxed muscles allow the tongue to block the pharynx in patients with a decreased level of consciousness.
- Use jaw-thrust method to manually open patient’s airway if patient has snoring respirations and has not completely emerged from anesthesia.

**Risk for Aspiration related to depressed cough and gag reflexes and reduced level of consciousness**

**Expected Outcome:** Patient will have clear lung sounds at all times.

- Position patient onto side, unless contraindicated, to protect the airway until fully awake.
- Have suction equipment always available to clear secretions or emesis.

**Evaluation.** The goal for ineffective airway clearance and aspiration is achieved if the patient’s airway remains patent and lung sounds remain clear. The goal for ineffective breathing pattern is met if the patient’s respiratory rate is within normal limits, no dyspnea is reported, and arterial blood gases are within normal limits.
Neurologic Function

Until its effects wear off, anesthesia can alter neurologic function. Patients may arrive in the PACU awake, arousable, or sleeping. Patients who are sleeping should become more alert during their stay in the PACU. As they emerge from anesthesia, they may become agitated or act wild for a short time; this is called emergence delirium. During this time, it is important to provide safety measures such as side rails and restraints—following restraint protocols—to protect IV lines and deep endotracheal (ET) tubes in place. Once resolv ed, the patient returns to calm state and has no recollection of the episode. Movement, sensations, and perceptions may also be altered by anesthesia. Movement is the first function to return after spinal anesthesia.

For older adults, it is important to review their history to understand if they have any cognitive or neurologic deficits. Confused patients may be agitated or frightened when they awaken. It is helpful to know how caregivers normally communicate with the patient. You should understand that the patient may not be able to report pain or follow commands. If possible, it may be helpful to have a familiar relative or caregiver with the patient in the PACU to calm him or her and help with communication. You should watch for nonverbal pain cues such as moaning, grimacing, rubbing of an area, and restlessness because you recognize that postoperative patients will have pain and require pain relief even if they cannot report it. If patients have limited movements or sensations before surgery, you should know this to obtain an accurate assessment of anesthetic effects.

DATA COLLECTION. A neurologic assessment includes level of consciousness; orientation to person, place, time, and event; pupil size and reaction to light; and motor and sensory function.

Pain

DATA COLLECTION. If the patient is awake, he or she is asked to rate the presence of pain using a scale, such as the 0-to-10 scale, a color scale, or pictures that rate pain. The location and character of the pain are documented. If the patient is not fully awake, vital signs and nonverbal indications of pain should be monitored. Nonverbal indications of pain can include abnormal vital signs, restlessness, moaning, grimacing, rubbing, or pulling at specific areas or equipment.

*Nursing Diagnoses, Planning, and Implementation

Pain related to tissue damage (mechanical [incision])

**EXPECTED OUTCOME** The patient will report that pain is relieved at a satisfactory level within 15 to 30 minutes of the pain report.

- Monitor the patient for pain, because pain may result from surgical procedure, movement, deep breathing, anxiety, a full bladder, positioning during surgery, NG tubes, catheters, IVs, ET tubes, or prior medical conditions, such as arthritis, cancer, or back pain.
- Give IV opioid analgesics promptly for their rapid onset.
- Begin PCA as ordered, because it is initiated in PACU.

EVALUATION. The goal for pain is met if the patient reports a satisfactory decrease in level of pain. For example, the patient reports pain of 10 on a scale of 0 to 10. You medicate the patient, and 30 minutes later, the patient rates pain as 2 on a scale of 0 to 10. The patient indicates that 2 is an acceptable pain level, so the goal is achieved.

Family Visitation

Family visitation in the PACU has been shown to be helpful to patients and their families. Allowing family visitation varies by hospital. Patients and families should be educated about the expectations for family visitation to keep it safe for the patient. During visitation, remember that the confidentiality of all patients must be ensured according to HIPAA (Health Insurance Portability and Accountability Act of 1996). For example, some patients may not want the surgical procedure revealed to their spouse or any family members.

Discharge From the Perianesthesia Care Unit

The length of stay in the PACU if the patient remains stable is normally about 1 hour. A postanesthesia recovery scale is used to score the patient’s readiness to be discharged. The scale rates categories such as respiration, oxygen saturation, level of consciousness, activity, and circulation. The anesthesiologist discharges the patient for transfer to a nursing unit, or home when discharge criteria are met (Box 12-5). The patient may be transferred to the ICU if patient status and/or frequent or invasive monitoring is needed.

<td><strong>Drainage or bleeding not excessive</strong></td>
</tr>
<tr>
<td><strong>Respiratory function not depressed</strong></td>
</tr>
<tr>
<td><strong>Oxygen saturation above 90%</strong></td>
</tr>
</tbody>
</table>

**Additional Criteria for Ambulatory Surgery**

- **No nausea or vomiting**
- **No IV opioids within last 30 minutes**
- **Voided if required by surgical procedure or ordered**
- **Is ambulatory or has baseline mobility**
- **Understands discharge instructions**
- **Provides means of contact for follow-up telephone assessment**
- **Released to responsible adult**
Transfer to Nursing Unit

The perianesthesia nurse gives a report of the patient’s condition to the unit nurse when the patient is transferred to the nursing unit. The patient is moved into bed on the nursing unit with assistance to prevent dislodging of IVs, tubes, and drains. After the patient is placed in bed, the following safety interventions are performed to help prevent falls:

• The bed is placed in its lowest position, with the side rails raised.
• The nurse’s call button is placed within easy patient reach and answered promptly.
• Patients are instructed that they should call for assistance with ambulation.
• When the patient gets up postoperatively, especially for the first time, he or she may be weak or dizzy. One or two health care workers should assist the patient and allow the patient to dangle before standing (Fig. 12.11).

Nursing Process for Postoperative Patients

A complete patient assessment is performed after transfer to the nursing unit. Respiratory status, vital signs (including temperature), level of consciousness, surgical site, dressings, and pain assessment are noted. IV site, patency, and IV solution and infusion rate are assessed and monitored. NG tubes are hooked to suction or clamped as ordered. Drains and catheters are positioned to promote proper functioning.

After discharge from the PACU, interventions to promote recovery include monitoring for complications (respiratory depression, hemorrhage, and shock), providing postoperative care, educating patients and their significant others, making needed referrals, and providing home health care. See the Nursing Care Plan for the Postoperative Patient.

Respiratory Function

DATA COLLECTION. Regular monitoring of the patient’s respiratory rate, depth, and effort and breath sounds as well as cough strength (if not contraindicated by the type of surgery, such as hernia repair or eye, ear, intracranial, jaw, or plastic surgery) should be done. Postoperative patients are at risk for developing atelectasis and pneumonia. They may have a weak cough as a result of being drowsy from anesthesia or analgesics. If fine crackles are heard in the lung bases, the patient should be encouraged to deep breathe or cough. Afterward you should listen again to see if the crackles have cleared. If the patient’s airway is compromised, immediate action is taken to support the airway and the surgeon is notified.

Nursing Diagnoses, Planning, and Implementation

Ineffective Breathing Pattern related to pain and analgesic medications

EXPECTED OUTCOME: Patient will maintain normal SaO₂ levels and normal arterial blood gases at all times.

• Encourage deep breathing to expand the lungs.
• Give analgesics as needed to promote deep breathing so the patient does not guard against deep respirations or coughing, especially if incision is near the diaphragm.

Ineffective Airway Clearance related to ineffective cough and secretion retention

EXPECTED OUTCOME: Patient will have a patent airway and clear breath sounds at all times.

• Encourage deep breathing and coughing every hour while the patient is awake, especially through the first postoperative day, to prevent mucous plugs that block bronchioles, causing alveoli to collapse and atelectasis or infection to develop from the stasis of mucus, resulting in pneumonia.
• Place the incentive spirometer within patient’s reach and encourage hourly use while awake to prevent atelectasis.
• Turn the patient at least every 2 hours to help expand the lungs and move secretions.
• Ambulate the patient as soon as possible because immobility decreases movement of secretions.

EVALUATION. If the patient’s breath sounds are clear and arterial blood gases remain normal, the goals have been met.

Circulatory Function

DATA COLLECTION. Monitor the patient’s circulatory status to detect and prevent hemorrhage, shock, and thrombophlebitis. Vital signs, SaO₂, and skin temperature, color, and moisture are monitored (per institutional policy) and compared with baseline data for abnormal trends. The incision or dressing is checked for drainage or hematoma formation. Drainage may leak down the patient’s side and pool underneath the patient. Turn the patient if able, or while wearing gloves slide hands underneath the patient to check for bleeding. Report any signs of hemorrhage or shock promptly.
The lower extremities of surgical patients are observed. Peripheral pulses and capillary refill are checked. Tenderness or pain in the calf may be the first indication of a deep venous thrombosis (DVT). Leg swelling, warmth, and redness, as well as fever, may also be present. Bilateral calf and thigh measurements are taken daily if DVT is suspected or diagnosed.

**Nursing Diagnoses, Planning, and Implementation**

**Deficient Fluid Volume related to blood and fluid loss or NPO status**

**EXPECTED OUTCOME:** Patient will maintain blood pressure and pulse within normal limits at all times.

- Monitor dressings, incisions, drains, and tubes for color and amount of drainage and report bright red drainage or excessive drainage amounts immediately to detect hemorrhage.
- Monitor I&O to detect imbalances.
- Maintain IV fluids at the ordered rate to maintain fluid volume.

**Ineffective Peripheral Tissue Perfusion related to interruption of blood flow during surgery, dehydration, and use of leg straps**

**EXPECTED OUTCOME:** Patient will maintain normal tissue perfusion at all times.

- Encourage leg exercises hourly while the patient is awake to prevent venous stasis and thrombosis.
- Assist with early postoperative ambulation as ordered to prevent thrombosis.
- Apply thigh-length graduated compression stockings (if contraindicated, use knee-length stockings) or intermittent pneumatic compression as ordered to help prevent stasis of blood. Thigh-length stockings are more effective than knee-length stockings in reducing the risk of thrombophlebitis (Fig. 12.12).
- Give anticoagulants or plasma expanders such as dextran 40 and dextran 70 as ordered to reduce clot formation.
- Avoid pressure under the knee from pillows, rolled blankets, or prolonged bending of the knee and elevate legs to help prevent venous stasis.

**NURSING CARE PLAN for the Postoperative Patient**

**Nursing Diagnosis:** Ineffective Airway Clearance related to ineffective cough and secretion retention

**Expected Outcomes:** Patient will maintain a patent airway at all times. Breath sounds remain clear at all times.

**Evaluation of Outcomes:** Is patient able to clear own secretions? Are breath sounds clear?

**Intervention** Monitor breath sounds. **Rationale** Abnormal breath sounds such as crackles or wheezes can indicate retained secretions. **Evaluation** Are breath sounds clear?

**Intervention** Encourage deep breathing and coughing and use of incentive spirometer hourly while awake. **Rationale** Lung expansion helps prevent atelectasis and keeps lungs clear of secretions. **Evaluation** Does patient perform deep breathing and coughing and use incentive spirometer?

**Intervention** Ensure that patient’s pain is relieved before activity. **Rationale** Movement can cause or increase pain. **Evaluation** Does patient state pain is controlled before activity?

**Intervention** Encourage movement by turning every 2 hours and ambulating as able. **Rationale** Movement promotes lung expansion and movement of secretions. **Evaluation** Is patient moving?

**Nursing Diagnosis:** Pain related to surgery, nausea, and vomiting

**Expected Outcomes:** Patient will report that pain management relieves pain satisfactorily within 30 minutes of report of pain. Patient will describe pain management plan by first postoperative day.

**Evaluation of Outcomes:** Does patient report satisfactory pain relief? Is patient able to describe pain management plan?

Postoperative Pain

Pain is common after surgery, although each patient’s pain experience varies. In addition to incisional pain, painful muscle spasms can occur. Nausea and vomiting, ambulation, coughing, deep breathing, and anxiety can cause discomfort and increase postoperative pain. Unrelieved pain has negative physiological effects. It also impairs deep breathing and coughing and hinders early ambulation, which may increase complications, length of hospital stay, and health care costs. It is important for nurses to stay informed of advances in pain management and ensure that they make pain relief a priority in providing patient care to reduce suffering and promote a quicker recovery (see Chapter 10).

DATA COLLECTION. If patients are not fully awake on transfer, vital signs and nonverbal indications of pain should be monitored (“Gerontological Issues”). Nonverbal indicators of pain may include abnormal vital signs (usually elevated blood pressure, although hypotension can occur in some patients), restlessness, moaning, grimacing, and rubbing or pulling at specific body areas or equipment. Patients who are awake are asked the location of the pain, to rate the presence of pain, and to describe the pain quality, such as sharp, ach ing, throbbing, or burning, which is then documented.

Gerontological Issues

Postoperative Pain

Pain is not a normal part of aging. Careful assessment of older patients’ unique aging changes, chronic diseases, and pain relief needs is required to appropriately treat their postoperative pain.

Cognitively impaired adults are at risk for undertreatment of their postoperative pain. Make these patients a priority to assess and provide pain relief at the start of your shift and throughout it. Pain rating scales are available for use with those who are cognitively impaired to determine if they are experiencing pain.

CRITICAL THINKING

Mrs. Owens

Mrs. Owens returned from a bowel resection 2 days ago. She is receiving 1000 mL of 0.9% normal saline solution over 10 hours on an IV controller pump.

1. As you monitor the patient, you understand that the IV pump rate would be set at what rate?
2. How many milliliters should you record as intake for 12 hours?
   - Intake for 12 hours:
     - One 8-ounce (oz) cup of coffee
     - 4 oz orange juice
     - 6 oz tomato soup
     - 3/4 cup gelatin
     - Two cups of water
     - 1200 mL of 0.9% normal saline solution IV
   - Output for 12 hours:
     - 1700 mL of urine

Suggested answers are at the end of the chapter.

Nursing Diagnoses, Planning, and Implementation

Pain related to tissue damage from surgery, muscle spasms, nausea, or vomiting

Expected Outcome: Patient will report pain relief at a satisfactory level using a pain rating scale within 30 minutes of pain report.

- Monitor pain using pain rating scale of 0 to 10 to identify patient’s needs.
- Provide medications promptly as ordered to relieve symptoms.
- Understand appropriate timing intervals between IV to intramuscular (IM) doses of analgesics so that patients do not wait and suffer needlessly after an IV analgesic. IV analgesics usually have a shorter duration than IM analgesics.
- Reposition patient to promote comfort.
Monitor the patient’s urinary status to evaluate urinary function.

Thirty minutes after pain medication is given, an evaluation may be needed if the patient is unable to void. After catheterization, efforts are made to promote voiding before inserting an invasive urinary catheter because of the risk of infection. If a patient reports the inability to void, the bladder is palpated for distention, or a bladder volume measurement is done, which determines the amount of urine in the bladder. You should be aware that restlessness can be caused by discomfort from a full bladder. A distended bladder requires intervention to empty it. Efforts are made to promote voiding before inserting an invasive urinary catheter because of the risk of infection.

The body’s stress response to the surgical experience stimulates the sympathetic nervous system ("fight-or-flight" response), which saves fluid by reducing urine output. Therefore, initially urine output may be reduced and concentrated. Then it should gradually increase, becoming less concentrated and lighter in color.

**Urinary Function**

**DATA COLLECTION.** Monitor the patient’s urinary status to ensure normal function is maintained after anesthesia administration. If the patient has a urinary catheter, the amount, color, and consistency of the urine are noted. Otherwise, watch for the patient’s first postoperative voiding to prevent bladder distention. Patients should void within 8 hours of their last voiding. Patients having urinary or gynecological procedures may need to void within 4 to 6 hours to prevent increased pressure on the surgical site. Catheterization may be needed if the patient is unable to void. After outpatient surgery, patients may be required to void before being discharged.

If a patient reports the inability to void, the bladder is palpated for distention, or a bladder volume measurement is done, which determines the amount of urine in the bladder. You should be aware that restlessness can be caused by discomfort from a full bladder. A distended bladder requires intervention to empty it. Efforts are made to promote voiding before inserting an invasive urinary catheter because of the risk of infection.

The body’s stress response to the surgical experience stimulates the sympathetic nervous system ("fight-or-flight" response), which saves fluid by reducing urine output. Therefore, initially urine output may be reduced and concentrated. Then it should gradually increase, becoming less concentrated and lighter in color.

**Nursing Diagnoses, Planning, and Implementation**

**Urinary Retention related to surgery, pain, anesthesia, altered positioning**

**EXPECTED OUTCOME:** Patient will completely and regularly empty bladder.

- Measure and record output on postoperative patients, especially those undergoing major procedures or urological surgery, older patients, and those with an IV or urinary catheter to detect urinary elimination problems.
- Report urinary output of less than 30 mL in 1 hour from the urinary catheter because this is typically the minimum acceptable output.

**CRITICAL THINKING**

Mrs. Wood

- Mrs. Wood, age 42, returns to the surgical unit after a hysterectomy. Her postoperative vital signs and assessment findings are normal. Mrs. Wood rates her pain level at 9, and the nurse notes that she moans occasionally, repeatedly moves her legs, and pulls at her covers near her abdominal incision. She is drowsy but repeatedly says it hurts. In the PACU, she received 10 mg of morphine IV 55 minutes ago. Morphine 5 to 10 mg IM is ordered every 3 hours as needed.

1. What nonverbal pain cues does Mrs. Wood display?
2. How should the nurse document Mrs. Wood’s pain?
3. What action should the nurse take to relieve Mrs. Wood’s pain?
4. When should the nurse next monitor Mrs. Wood’s pain level?
5. If Mrs. Wood indicates that her pain is unrelieved after 30 minutes, what action should the nurse take and with which team members will the nurse collaborate?
6. The nurse is to give Mrs. Wood morphine 8 mg IM now. Morphine 10 mg/mL is available. How many milliliters will the nurse give?

*Suggested answers are at the end of the chapter.*
• Recognize that patients who are voiding small amounts frequently (30–50 mL every 20 to 30 minutes) or who dribble may have retention overflow and may not be emptying their bladder. This is not normal and may require catheterization to empty the bladder and prevent complications.
• Assist patients to the bathroom or bedside commode, and allow men to stand or sit to urinate if possible to promote voiding.
• Warm bedpans to prevent reflexive sphincter tightening.
• Use techniques to promote voiding before catheterization for the patient who is unable to void (running water, pouring warm water over a female patient’s perineum, or drinking a hot beverage to stimulate voiding) because catheterization increases the risk of infection.
• Provide privacy after safety is ensured to promote voiding.
• Have patients place their feet solidly on the floor to relax the pelvic muscles to aid voiding.
• Notify the surgeon if the patient is uncomfortable, has a distended bladder, or has not voided within the specified time frame to obtain treatment orders.

EVALUATION. The goal for urinary retention is met if the patient is able to void without pain or complications.

Surgical Wound Care

A puncture wound has a small opening and is made to insert a tube or drain. An incision is a wound made by a surgeon with a sharp instrument such as a scalpel. Incisions are closed with sutures, staples (Fig. 12.13), or surgical adhesives, or adhesive strips. As the wound heals, sutures or staples are removed in 7 to 10 days.

Wounds can be clean or dirty. Clean wounds are surgical wounds that are not infected. Dirty (contaminated) wounds include accidental wounds or surgical incisions exposed to GI contents or unsterile conditions. Infected wounds contain microorganisms from trauma, ruptured organs, or infection. Necrotic and infected tissue is removed before infected wounds are closed. This is known as débridement.

WOUND HEALING. Wound healing occurs in phases (Table 12.9). Wounds can heal by first (primary) intention, second (secondary) intention, and third (tertiary) intention (Fig. 12.14). In first-intention healing, the edges of the wound are approximated with staples or sutures. This usually results in minimal scarring. To heal by second intention, the wound is usually left open and allowed to heal by granulation. Scarring is usually extensive with prolonged healing. For healing by third intention, an infected wound is left open until there is no evidence of infection and the wound is then surgically closed.

WOUND COMPLICATIONS. Wound problems can include hematoma, infection, dehiscence, and evisceration. A hematoma occurs from bleeding in the wound and into the tissue around the wound. A clot forms from the bleeding. If the clot is large with swelling, the clot may need to be removed by the surgeon.

Infected wounds may be warm, reddened, and tender and have purulent drainage (pus). The drainage may have a foul odor. A fever and elevated white blood cell (WBC) count may be present. Antibiotics are used to treat the infection.

Dehiscence and evisceration are serious wound complications (Fig. 12.15). Wound dehiscence is the sudden bursting open of a wound’s edges, which may be preceded by an increase in serosanguineous drainage. Evisceration is the viscera spilling out of the abdomen. Dehiscence and evisceration often occur with abdominal incisions in patients who are malnourished, obese, older, or who have poor wound healing. Supporting the wound during coughing and other activities that pull on the incision or applying an abdominal binder on patients who are at risk helps prevent dehiscence and evisceration. When evisceration occurs, the patient may have pain and vomiting and may report that “something let loose” or “gave way.”

**BE SAFE!**

If dehiscence or evisceration occurs:

- Place the patient in low Fowler’s position with flexed knees.
- Cover the wound with sterile dressings or towels moistened with warm sterile normal saline.
- Notify the surgeon immediately of this surgical emergency.
- Apply gentle pressure over the wound and keep the patient still and calm.
- Monitor vital signs for evidence of shock (e.g., tachycardia, tachypnea, dyspnea, hypotension).
- Infuse IV fluids as ordered.
- Prepare the patient for immediate surgery to close the wound.

For dehisced surgical incisions that resist healing, vacuum-assisted closure (VAC) aids in healing the incision (see Chapter 54). VAC applies negative pressure to wound edges. The device can also be used on other types of wounds.

**WORD-BUILDING**

- serosanguineous: sero—whey + sanguineous—bloody
- evisceration: e—out + viscera—body organs

FIGURE 12.14 Wound healing. (A) Primary intention. Wound healing occurs in a clean wound, such as a surgical wound, for which edges are approximated, typically with staples or sutures. Healing occurs quickly with slight scarring. (B) Secondary intention. Large irregular or infected wounds are left open to allow healing to occur from the inside out. Pressure ulcers or chronic wounds are often treated this way. Large scarring occurs with lengthy healing time. (C) Tertiary intention. Infected or contaminated wound is left open for a brief time period until wound is clean. Granulation tissue fills in for some wound healing, and then edges are approximated and closed surgically. Wider scarring occurs.
DATA COLLECTION.

Drains. Drains are inserted into wounds during surgery to prevent accumulation of blood, lymph, or necrotic tissue in wounds that can lead to infection or delayed healing. Drains may work by gravity or suction. Penrose drains are soft, flat, drains that carry drainage from the wound. Moderate, pink serosanguineous (consisting of blood and serous fluid) drainage is expected from a Penrose drain and may require frequent dressing changes. Examples of drains that use suction to gently enhance drainage include the Jackson-Pratt and Hemovac (www.zimmer.com). These drains are closed systems that may require periodic emptying and reapplication of the suction by compressing the drain.

Output is recorded when the drainage is emptied. The amount of drainage expected varies with the type of surgery. Be alert for excessive amounts to report. Specialized drainage systems allow the transfusion of drainage containing blood back to the patient (autotransfusion) to maintain hemoglobin levels without the risks associated with blood transfusions, such as transfusion reactions or transmission of infections.

Dressings. Dressings protect the wound, absorb drainage, prevent contamination from body fluids, provide comfort, and apply pressure to reduce swelling or bleeding as in a pressure dressing. The initial dressing is applied in surgery and then is usually removed by the surgeon approximately 24 hours postoperatively. If drainage appears on the initial dressing, reinforce it with another dressing, according to surgeon orders or institution policy.

After the initial dressing is removed, if the wound is dry and the edges intact (approximated), the surgeon can order the wound to be left uncovered. This allows easy observation of the wound and avoidance of applying tape to the skin. Draining wounds are dressed with several layers that are changed as needed. When the old dressing is removed, it should be done carefully to prevent dislodging of tubes or drains. The condition of the wound is documented with each dressing change. It is normal for the incision to be puffy and red from the inflammatory response. The surrounding skin should be the patient’s normal color and temperature. Correct tape application over the dressing is done by gently laying the tape over the dressing and applying even pressure on each side of the wound. Pressure should not be applied on top of the wound by pulling on the tape from one side of the wound to the other side.

EVIDENCE-BASED PRACTICE

Clinical Question
Do wound dressings prevent surgical site infection in people with surgical wounds healing by primary intention?

Evidence
A review of 16 randomized controlled trials of 2578 subjects looked at the use of wound dressings versus leaving postoperative surgical wounds healing by primary intention uncovered. No reduction in surgical site infection was found related to covering surgical wounds with dressings.

Implications for Nursing Practice
Dressings should be selected based on their cost and purpose, such as exudate absorption.

Chapter 12 Nursing Care of Patients Having Surgery

Nursing Diagnoses, Planning, and Implementation

Impaired Skin Integrity related to surgical incision

Expected Outcome Patient will regain skin integrity within [specify individualized realistic time frame].

- Monitor skin color and temperature and report changes to detect need for treatment.
- Monitor dressings and note drainage color, amount, and consistency. Surgical wound drainage initially is sanguineous (red) and changes to serosanguineous (pink) and then serous (pale yellow) after a few hours to days.
- Promptly report drainage that is bright red, remains sanguineous after a few hours, or is profuse to the surgeon because the patient may be hemorrhaging.
UNIT TWO  Understanding Health and Illness

Gastrointestinal Function

Nutritional intake and bowel function can be affected by surgery and anesthesia. Being NPO and having bowel preparation often occur preoperatively. After abdominal surgery, peristalsis and bowel sounds, and flatus usually stop (paralytic ileus) for 24 to 72 hours. Flatus, bowel movements, and an appetite signal the return of GI function. Interventions to shorten ileus time include the following:

- Medication such as Alvimopan (Entereg) 12 mg, which is given 30 to 90 minutes before surgery and twice daily for up to 15 doses in 7 days to increase recovery of the functioning of the GI tract after partial small or large bowel resections
- Use of minimally invasive surgery
- Chewing gum
- Ambulation
- Avoidance of NG tubes when able as complications and later feeding occur
- Early feeding

EVALUATION. The goal for impaired skin integrity is met if the patient’s wound heals and skin integrity is regained without delayed healing or complications.

Nursing Diagnoses, Planning, and Implementation

Imbalanced Nutrition: Less Than Body Requirements related to NPO, pain, and nausea

**EXPECTED OUTCOME:** Patient will resume normal dietary intake and maintain weight within normal limits.

- Maintain IV fluids, total parenteral nutrition, or enteral feedings until the patient resumes oral intake (“Nutrition Notes”).
- Try water and clear liquids at first as ordered, then advance the diet to promote tolerance.
- Give antiemetics as ordered to control nausea and vomiting.

Constipation related to decreased peristalsis, immobility, altered diet, opioid side effect

**EXPECTED OUTCOME:** The patient will return to normal bowel elimination patterns and report freedom from gas pains and constipation within 3 to 4 days postoperatively.

- Encourage early ambulation and exercise to promote restoration of GI function.
- Encourage ambulation, have patient lie prone, and pull the knees up to the chest if gas pains occur to relieve the pain.
- Monitor elimination and document to detect problems.
- Provide stool softeners or laxatives as ordered to prevent constipation.

**EXPECTED OUTCOME:** Patient will resume normal dietary intake.

**EXPECTED OUTCOME:** Patient will tolerate bowel preparation and report freedom from nausea, vomiting, and bloating.

**EXPECTED OUTCOME:** The patient will return to normal bowel elimination patterns and report freedom from gas pains and constipation within 3 to 4 days postoperatively.

**EXPECTED OUTCOME:** The patient will resume normal dietary intake.

**EXPECTED OUTCOME:** The patient will return to normal bowel elimination patterns and report freedom from gas pains and constipation within 3 to 4 days postoperatively.

EVALUATION. The goal for the Imbalanced Nutrition: Less Than Body Requirements nursing diagnosis is met if patients are able to maintain their baseline weight and resume a normal dietary intake. The goal for constipation is met if patients are free from discomfort and establish a regular bowel elimination pattern.

**Nutrition Notes**

Nourishing the Postoperative Patient

After surgery, IV 5% glucose in water is commonly prescribed. Two liters of this solution contain only 340 calories, which is insufficient to meet the patient’s energy needs but enough to prevent ketosis from breakdown of adipose tissue. Previously well-nourished adults generally have nutrient reserves for 3 to 4 days of semistarvation. To prevent excessive muscle protein from being used for energy, adequate nourishment should be delivered to the patient within 3 days. (Citrotein and Enli ve can be used to supplement clear liquid diets.)

To avoid abdominal distention, oral feedings traditionally have been delayed until peristalsis returns but scientific evidence supporting this practice is lacking. Researchers are beginning to test the practice. In some situations, delaying oral intake seems to offer no advantage in preventing complications over earlier resumption of feeding.

Patients usually progress from clear liquids to a regular diet as soon as possible. If “diet as tolerated” is prescribed, the patient should be asked what sounds good. Sometimes a full dinner when the patient doesn’t feel well “turns off” the appetite.

After GI surgery, oral food and fluids are deferred longer than with other surgeries to allow healing. When particular amounts are prescribed, those limits should be strictly implemented to preserve the suture lines. After surgery on the mouth and throat, no red liquids are given so that bleeding can be seen and vomitus is not mistaken for blood.

Specific nutrients necessary for healing are:

- Vitamin C for collagen formation
- Vitamin K for blood clotting

To prevent excessive muscle protein from being used for energy, adequate nourishment should be provided as soon as possible after surgery. After GI surgery, oral food and fluids are deferred longer than with other surgeries to allow healing. When particular amounts are prescribed, those limits should be strictly implemented to preserve the suture lines. After surgery on the mouth and throat, no red liquids are given so that bleeding can be seen and vomitus is not mistaken for blood.

Specific nutrients necessary for healing are:

- Vitamin C for collagen formation
- Vitamin K for blood clotting

**EXPECTED OUTCOME:** The patient will return to normal bowel elimination patterns and report freedom from gas pains and constipation within 3 to 4 days postoperatively.
• Encourage patients to move themselves
• Turn at least every 2 hours, alternating from supine to side
• Position patient in bed with pillows

Normal physical activity.

Strength, and movement restriction

Impaired Physical Mobility related to surgery, decreased
Nursing Diagnoses, Planning, and Implementation

DATA COLLECTION. It is important for the patient to move as much as possible to prevent complications and promote healing. Pain, incisions, tubes, drains, dressings, and other equipment may make movement difficult. You should determine the patient’s ability to move in bed, to get out of bed, and to walk. Pain levels that may interfere with movement are assessed. The patient’s tolerance to activity is observed. Patient understanding of how to perform exercises is noted.

It is important for the patient to move as much as possible to prevent complications and promote healing. Pain, incisions, tubes, drains, dressings, and other equipment may make movement difficult. You should determine the patient’s ability to move in bed, to get out of bed, and to walk. Pain levels that may interfere with movement are assessed. The patient’s tolerance to activity is observed. Patient understanding of how to perform exercises is noted.

NURSING CARE TIP
Most IV solutions do not provide enough nutrients or calories to prevent malnutrition. The primary purpose of most IV fluids is to provide hydration. A 1000-mL IV solution containing 5% dextrose provides only about 170 calories. This does not meet an adult’s daily caloric needs, especially if healing is occurring. You should ensure that early consideration of other nutritional methods is made to meet the patient’s dietary needs.

Mobility

DATA COLLECTION. It is important for the patient to move as much as possible to prevent complications and promote healing. Pain, incisions, tubes, drains, dressings, and other equipment may make movement difficult. You should determine the patient’s ability to move in bed, to get out of bed, and to walk. Pain levels that may interfere with movement are assessed. The patient’s tolerance to activity is observed. Patient understanding of how to perform exercises is noted.

Nursing Diagnoses, Planning, and Implementation

Impaired Physical Mobility related to surgery, decreased strength, and movement restriction

EXPECTED OUTCOME. Patient’s goal will be to resume normal physical activity.

• Position patient in bed with pillows to support the body in good alignment.
• Turn at least every 2 hours, alternating from supine to side to side if not contraindicated, to prevent complications.
• Encourage patients to move themselves to increase circulation and promote lung expansion.
• If ambulation is not possible, encourage hourly exercises (deep breathing, range of motion of all joints, and isometric exercises of the abdominal, gluteal, and leg muscles) while awake to prevent complications.
• If patient cannot perform active range-of-motion exercises, perform passive joint range of motion to prevent complications.
• Raise the head of the bed slowly to let the circulatory system adjust to the position change.
• If patient reports dizziness or feeling faint, lower the head of the bed to let the circulatory system adjust more slowly.

• Dangle patient’s feet on the side of the bed to prepare for ambulation (see Fig. 12.11).
• If dangling is tolerated, ambulate the patient. Before getting up, patient should pedal the feet to “wake up” the muscles controlling the arteries. To rise, patient should keep eyes forward and move slowly until feeling adjusted to being up. Usually the patient ambulates a short distance the first time and increases the distance as tolerated. One or two health care workers should assist the patient and use a gait (walking) belt for safety. Walkers with wheels and seats also may be used for support and for resting if the patient becomes dizzy or tired. If patient feels faint or dizzy or if vital signs change, help patient back to bed. A wheelchair may be needed for safe transport back to the room.

EVALUATION. The goal for impaired physical mobility is met if the patient can increase ambulation and resume normal activities.

Postoperative Patient Discharge

Discharge planning begins during preadmission testing and continues after admission to ensure that the patient is ready for a timely discharge. When the patient meets discharge criteria, the surgeon discharges the patient.

Ambulatory Surgery

DISCHARGE CRITERIA. Usually, a patient can be considered a candidate for discharge 1 hour after surgery if the PACU discharge scoring system or clinical discharge criteria are met (see Box 12-5). Clinical discharge criteria include stable vital signs, no bleeding, no nausea or vomiting, and controlled pain that is not severe. Depending on the type of surgical procedure, such as urological, gynecological, or hernia surgery, the patient may be required to void before discharge. The patient also should be able to sit up without dizziness before discharge. Patients meeting discharge criteria are discharged by the surgeon and released to a responsible adult. Patients are not permitted to drive themselves home because of the effects of anesthesia and medications they have received.

DISCHARGE INSTRUCTIONS. Patients and their families are given written discharge instructions before discharge. Older patients should have a caregiver participate in the discharge instruction session to understand what observations to make and what to do if complications develop. The instruction form is signed by the patient or an authorized representative to indicate understanding. Prescriptions and a copy of the instructions, to provide a reference for later, are sent with the patient. The patient is encouraged to rest for 24 to 48 hours. The patient is to avoid operating machinery, driving, drinking alcoholic beverages, and making major decisions for 24 hours because the effects of undergoing surgery can alter energy levels and thinking ability. The surgeon orders any fluid, dietary, activity, or work restrictions.

Patients are taught wound care, medication information (including side effects), and signs and symptoms of complications to report to the surgeon. Phone numbers for the surgeon, surgical facility, and emergency care are provided.
Inpatient Surgery

**DISCHARGE CRITERIA.** The surgeon determines the patient’s readiness for discharge from the hospital. Postoperative lengths of stay vary based on the surgical procedure and the patient’s individual needs. Before discharge, a complete assessment of the patient is performed and documented.

**DISCHARGE INSTRUCTIONS.** All necessary teaching is completed before discharge (Fig. 12.16). Patients and their families or caregivers are given prescriptions and a copy of written instructions that are signed by the patient to indicate understanding before discharge. If more teaching or reinforcement is needed, a referral to a home health nurse can be requested.

The surgeon orders any fluid, dietary, activity, or work restrictions. Patients are taught wound care, medication information (including side effects), and signs and symptoms of complications to report to the surgeon. Patients are informed of the date for their follow-up visit to the surgeon.

**FIGURE 12.16** Nurse providing discharge teaching to patient.

---

**Home Health Hints**

A referral for a home health nurse to assist a patient in the recovery process is made when the patient needs skilled nursing care following surgery (See Chapter 16, “Nursing Care of Patients at Home,” for examples of skilled care).

It is helpful for caregivers to keep a notebook in the hospital and continue it at home. Treatments, medicines, observations, procedures, HCP and nurse visits, instructions, and therapies with dates and times can be recorded. This helps prevent confusion, prepares the next caregiver, and affords better organization of time and resources for everyone. Families of patients recovering from surgery can provide items to keep the patient occupied and comfortable: talking books, electronic reading tablet, inspirational reading material, pictures, favorite pajamas, robe and slippers, and coverlet.

After a patient comes home from surgery, the home care nurse can help give direction to the family to prepare the room where the patient will be staying:

- It is helpful if the room can be on the same floor with the bathroom, kitchen, and living space.
- If an extended recovery period or illness is expected, the den or living room might be considered as the primary living space to provide room for equipment and make companionship easier.

The patient can see activity in the home and be included in family activity. Also, caregivers can be more attentive to the patient’s needs and save countless footsteps.

Reinforce any discharge instructions the patient and caregivers bring home with them. Although these instructions are reviewed by the surgeon and hospital nurses, frequently the patient and family are tired and anxious and can miss important details. If possible keep a copy of these instructions in the patient’s home health folder in order to communicate to all members of the health care team.

Special equipment may be needed, including the following:

- For the patient on bedrest, a hospital bed with full side rails helps with a variety of position changes and better height for the caregiver.
- Draw sheets made of folded twin sheets are needed, as well as extra pillows for positioning and splinting.
- A bedside stand is needed for personal and toilet articles.
- A bedside commode can be placed near the bed if the patient cannot walk to the bathroom. A bedpan or urinal may be needed. A functional female urinal is easier to use than a bedpan.
- A flexible tube with a showerhead that connects to the bathtub faucet is convenient and allows the patient more independence in bathing.
- Installation of grab bars and tub stools and skid-proofing of a shower or tub are important safety measures to help prevent falls.
- If the patient is eligible for insurance coverage for durable medical equipment, a HCP’s order must be obtained.
- If the patient is discharged on anticoagulants and/or antiembolic stockings, reinforce instructions and importance of adherence to them for prevention of deep vein thrombosis.
- Monitor nutritional status to assist with wound healing. Discuss need for supplementation with RN.
- Instruction on wound care to the patient and family includes hand hygiene before and after wound care to prevent infection. Reinforce frequently.
- If discharged on oral pain medication discuss pain management and potential side effects (See Chapter 10, “Nursing Care of Patients in Pain,” for further details).
CRITICAL THINKING

Mrs. Owens
1. 100 mL per hour. IV pumps are always set to deliver the amount of milliliters per hour. Divide the total volume of 1000 mL by the total time of 10 hours = 100 mL per hour.
2. Intake = 2400 mL.
   To calculate this:
   Remember your conversions:
   30 mL = 1 oz
   1 cup = 8 oz (don’t supersize the cup!)
   Calculations:
   1 8-oz cup of coffee = 1 × 8 × 30 = 240 mL
   4 oz orange juice = 4 × 30 = 120 mL
   6 oz tomato soup = 6 × 30 = 180 mL
   3/4 cup gelatin = 3/4 × 8 × 30 = 180 mL
   2 cups of water = 2 × 8 × 30 = 480 mL
   1200 mL of 0.9 normal saline IV
   The patient’s output does not affect the intake total, so it is not used for this calculation.

Mrs. Wood
1. Moaning occasionally, moving legs restlessly, and pulling covers near abdominal incision are non-verbal pain cues.
2. Document pain levels by actual observations: occasional moaning, restless leg movements, and pulling of covers near abdominal incision. By patient’s statement: “It hurts.” Because Mrs. Wood is too drowsy to use the pain scale, other data are used. When Mrs. Wood is more awake, explanation of the pain scale should be reinforced and used.
3. Review pain medication orders to determine if analgesics can be given. Noting that an IV analgesic was given 50 minutes ago and the IM analgesic is ordered every 3 hours, request that the surgeon or pharmacist be consulted to determine appropriate time intervals. The patient should not have to wait 3 hours to receive the next dose of pain medication. If the consultation indicates it is time to give the analgesic, verify that vital signs are still stable and then give the analgesic. Also consider other pain relief measures such as patient warmth, positioning, or environmental issues such as bright lighting, room temperature, and noise.
4. After administration of the analgesic, Mrs. Wood’s pain level should be assessed in at least 30 minutes to determine pain relief. If Mrs. Wood is asleep, she should not be awakened unless it is necessary. Nonverbal cues should be observed and respirations counted and documented. If no indication of pain is noted, Mrs. Wood’s pain level should be monitored at least hourly or as needed.
5. Document pain level on scale of 0 to 10. Collaborate with the surgeon for notification of inadequate pain relief and the pharmacist for safe time intervals for ordered analgesic routes. The patient should not have to wait the 3-hour interval if in pain. Consider providing other pain relief measures while the surgeon is being notified.
6. Try unit analysis for solving mathematical calculations. It is easy to understand, and our students say it is a helpful method.
   Unit Analysis Method:
   \[
   \frac{8 \text{ mg}}{1 \text{ mL}} \quad \frac{1 \text{ mL}}{10 \text{ mg}} = \frac{8}{10} = 0.8 \text{ milliliter}
   \]
REVIEW QUESTIONS

1. The nurse is contributing to the plan of care for a preoperative patient. Which of the following nursing actions should the nurse implement to reduce surgical risk factors for the preoperative patient? Select all that apply.
   1. Playing music of patient’s choice
   2. Avoiding discussion of fears
   3. Reinforcing pain control methods
   4. Showing use of incentive spirometer
   5. Monitoring blood glucose for a patient with diabetes
   6. Teaching to perform leg exercises hourly while awake

2. The LPN/LVN is caring for a preoperative patient. Which of the following roles can the LPN/LVN provide for the patient’s care in the preoperative phase?
   1. Assisting in data collection
   2. Explaining the surgical procedure
   3. Obtaining preoperative orders
   4. Conducting the preoperative anesthesia interview

3. The LPN/LVN is caring for a patient preoperatively who is to sign consent for surgery. Which of the following is within the LPN/LVN’s scope of practice related to the patient providing consent for surgery? Select all that apply.
   1. Witnessing minor patient’s signature on the consent
   2. Providing informed consent
   3. Answering surgical procedure questions
   4. Requesting patient questions be referred to surgeon
   5. Witnessing the patient’s signature on the consent
   6. Reading the consent to a patient before he or she signs it

4. The nurse is contributing to the teaching plan for an older adult. Which of the following is a teaching strategy that improves learning for the older adult?
   1. Sit near a window with bright sunlight.
   2. Use large black-on-white printed materials.
   3. Sit beside patient.
   4. Use blue and green colors for brochures.

5. The nurse is contributing to the plan of care for a patient undergoing a cholecystectomy. Which of the following interventions would help prevent atelectasis for this patient? Select all that apply.
   1. Coughing and deep breathing
   2. Holding breath while moving
   3. Restricting fluids
   4. Leg exercises
   5. Pain control
   6. Ambulation

6. The nurse is caring for a patient after thoracic surgery. Which of the following would the nurse evaluate as indicating that interventions to prevent respiratory complications have been effective?
   1. Pain level “2”
   2. No abdominal distention
   3. Clear lung sounds
   4. Good appetite

7. The nurse is caring for a patient who returned from surgery 3 hours ago. Which of these findings would the nurse recognize as being the most urgent to report to the surgeon?
   1. Tachycardia
   2. Polyuria
   3. Nausea
   4. Fever

8. The nurse is assisting with data collection on an ambulatory postoperative patient. Which of the following criterion would the nurse evaluate as indicating patient readiness for discharge after ambulatory?
   1. Ability to drive an automobile
   2. Ability to ambulate 50 feet
   3. Being pain free
   4. Absence of nausea or vomiting

9. What is the role of the home health nurse in caring for postoperative patients? Fill in the blank.
   Answer: ______________________________________

Answers can be found in Appendix C.

Nursing Care of Patients With Emergent Conditions and Disaster/Bioterrorism Response

LEARNING OUTCOMES

1. Explain the components of the primary survey.
2. Plan nursing interventions for a trauma victim.
3. Identify the symptoms of inhalation injury.
4. Describe the stages of hypothermia.
5. Describe the stages of hyperthermia.
6. Explain the priorities of care for poison overdose.
7. Discuss the LPN/LVN role in crisis situations and psychiatric emergencies.
8. Describe the LPN/LVN role in identifying a bioterrorist attack or disaster response.
The ability to recognize an emergent condition, prioritize, and provide quick assessments and interventions is essential in nursing. Upon arrival in the emergency department (ED), most patients are triaged by a registered nurse (RN). During the triage process, the RN evaluates the patient’s condition, asks appropriate questions related to the condition, and performs a rapid assessment of the patient to provide the appropriate level of care (Fig. 13.1). This chapter presents specific emergent conditions with application of the nursing process.

**PRIMARY SURVEY**

What do you think the nurse does first when a patient arrives in the ED? Well, to recognize life-threatening conditions and determine priorities of care, an initial assessment of the patient’s airway, breathing, circulation, and disability is conducted. This process is known as the primary survey. The components of the primary survey are listed in Table 13.1.

**A—Airway**

The airway is the most important component of the primary survey. The neck should not be hyperextended, flexed, or rotated until spinal injury is ruled out because any movement can worsen an existing cervical spine injury. During cardiopulmonary resuscitation (CPR), if there is a possible or known spinal injury, the jaw-thrust maneuver rather than the chin-lift maneuver must be used to avoid moving the head and neck (Fig. 13.2). The airway is inspected for obstruction, including loose teeth, foreign objects, bleeding, and vomitus. Next, any visible airway obstructions are removed using suction.

Airway adjuncts, such as nasopharyngeal or oropharyngeal airways, can be used to keep the airway open. When additional airway support and mechanical ventilation are required, advanced airway adjuncts, such as endotracheal intubation or cricothyroidotomy, can be performed by specially trained emergency personnel or health care providers.

**B—Breathing**

After the airway is opened, the patient is assessed for spontaneous breathing and respiratory rate and depth. The nurse observes whether the patient’s chest rises and falls spontaneously and auscultates for breath sounds bilaterally. If the patient is not breathing, interventions are performed before proceeding. The patient can be ventilated with a mouth-to-face mask or a bag-valve face mask. Endotracheal intubation is the preferred method of maintaining an airway in an unconscious patient because it opens the airway and protects the lungs from aspiration (see Fig. 29.23).
interrupted 3.3 times each hour, and 27.5% of these interruptions occurred during medication administration (Kosits & Jones, 2011). Other studies have demonstrated that temporary staff in emergency made more medication errors, resulting in greater harm than permanent staff members (Pham et al, 2011). Contributing factors to the high rate of medication errors included ED overcrowding, the increased volume of medications given in the ED, increased numbers of complicated and chronically ill patients, frequency of verbal orders, time pressure, and interruptions and distractions (Blank et al, 2012).

Implications for Nursing Practice
Medication errors can result from the acute, crowded, and fast-paced nature of emergency care. Nurses and health care agencies need to be aware of the causes and types of medication errors and maintain vigilance in following interventions that can reduce the incidence of error such as following the five rights of medication administration, reducing distractions and interruptions during administration, and double checking high-risk medications with another nurse (Athanasakis, 2012).

REFERENCES
compensatory mechanisms fail, resulting in inadequate tissue and cellular perfusion and causing cell death if left untreated. In the third and final stage, decompensated, the patient will no longer respond to treatment.

There are four types of shock: hypovolemic, cardiogenic, obstructive, and distributive.

**Hypovolemic shock** signs and symptoms are caused by a decrease in the circulating blood volume. **Cardiogenic shock** signs and symptoms result from cardiac failure. **Obstructive shock** caused by a blockage of blood flow in the cardiovascular circuit outside the heart results in signs and symptoms of reduced blood flow and oxygenation. **Distributive shock** caused by excessive dilation of the veins and arterioles causes signs and symptoms of decreased blood pressure. Therapeutic interventions for shock are listed in Box 13-1.

**Pathophysiology**

**Anaphylactic shock** is a form of distributive shock. There is no loss of blood, but excessive vasodilation occurs. Bronchi constrict, and air movement into the lungs becomes increasingly difficult. Increased fluid and mucus are secreted into the bronchial passages. Fluid in the air passages and constricted bronchi cause wheezing. The body is rapidly deprived of needed oxygen by this respiratory system reaction. Signs of severe anaphylaxis include hypotension due to vasodilation, decreased level of consciousness due to decreased oxygenation, and respiratory distress with stridor and cyanosis due to airway constriction and fluid.

**ANAPHYLAXIS**

Anaphylaxis is a severe allergic reaction. The reaction can occur suddenly after initial contact with an allergen or after any subsequent exposure. Signs and symptoms result from a massive release of chemical mediators from mast cells and basophils throughout the body (Box 13-2). Chemical mediators lead to vasodilation and capillary leakage, which results in hypotension and eventually vascular collapse.

**Nursing Care Tip**

One of the increasing causes of anaphylactic shock is latex allergy reaction. This type of allergy is on the rise among healthcare workers as a result of repeated exposure to health care products made with latex, such as gloves. The use of latex-free products limits exposure and reduces the risk of developing this allergy.

**Pathophysiology**

**Anaphylactic shock** is a form of distributive shock. There is no loss of blood, but excessive vasodilation occurs. Bronchi constrict, and air movement into the lungs becomes increasingly difficult. Increased fluid and mucus are secreted into the bronchial passages. Fluid in the air passages and constricted bronchi cause wheezing. The body is rapidly deprived of needed oxygen by this respiratory system reaction. Signs of severe anaphylaxis include hypotension due to vasodilation, decreased level of consciousness due to decreased oxygenation, and respiratory distress with stridor and cyanosis due to airway constriction and fluid.

- Generalized itching and flushing
- Urticaria (hives)
- Swelling of the lips, tongue, or uvula
- Dyspnea
- Bronchospasm, wheezing, and stridor
- Chest tightness and cough
- Crampy abdominal pain and vomiting
- Anxiety
- Hypotension
Chapter 13  Nursing Care of Patients With Emergent Conditions and Disaster/Bioterrorism Response  241

Nursing Process for the Patient Experiencing Shock or Anaphylaxis

Data Collection

When monitoring a patient at risk for shock, be aware of the signs and symptoms common to all types of shock (Box 13-3). It is important to note the patient’s initial level of consciousness and monitor the patient for any subsequent changes. A progressive decline in level of consciousness indicates an urgent need for intervention. Pulses indicate the strength of the heart’s contractions. Because a pulse is an immediate indicator of the patient’s condition, it should be taken frequently during any emergency condition. Changes in blood pressure can indicate changes in blood volume. Blood pressure changes can occur rapidly but usually not as swiftly as pulse changes.

Skin temperature and color changes can occur with shock. Severe blood loss activates the “fight-or-flight” response in the sympathetic nervous system, which causes the skin to become cool and clammy. This occurs when peripheral blood vessels constrict to shunt blood to vital organs. Skin color depends on the presence of circulating blood in the vessels of the skin. Pale, white, or ashen skin indicates insufficient circulation. In patients with deeply pigmented skin, color changes can be seen in the nailbeds, conjunctiva of the eye, or mucous membranes of the mouth.

Capillary refill is checked on nailbeds to evaluate arterial circulation to an extremity. The nailbed is compressed to produce blanching (lighter color change), released, and the seconds counted until color returns to the blanched area. Normally, nailbed color should return within 3 seconds after the pressure is released. Older adults can normally have a delayed refill time. Patients in shock can have delayed or absent capillary refill.

LEARNING TIP

Gently squeeze and release your own nailbed. Do you see the color change? Count the seconds until the color returns. That is your capillary refill time.

Box 13-3 Common Signs and Symptoms of Shock

- Restlessness and anxiety
- Weak, rapid, thready pulse
- Cold and clammy skin
- Pale skin color
- Shallow, rapid, labored breathing
- Gradually and steadily falling blood pressure
- Alteration in consciousness in severe shock state
- Thirst

Risk for Shock related to hypotension, hypovolemia, or hypoxia

Expected Outcome: The patient will maintain vital signs within normal baseline range.

- Obtain frequent vital signs and oxygen saturation to monitor patient status.
- Administer oxygen to maintain SpO2 greater than 90%.
- Maintain isotonic IV fluids, as ordered, to maintain fluid volume and thus blood pressure.
- Monitor intake and output to monitor fluid status.

Risk for Ineffective Peripheral Tissue Perfusion related to decreased circulating blood volume secondary to internal and/or external bleeding

Expected Outcome: The patient’s bleeding will be controlled to maintain vital signs within limits normal for the individual.

- Apply direct pressure to external bleeding site to stop the flow of blood and allow normal coagulation to occur.
- Elevate the bleeding limb and combine with direct pressure to help stop bleeding.
- When direct pressure and elevation do not control hemorrhage, pressure-point control should be attempted to stop the bleeding (Fig. 13.3). The chosen artery for pressure-point control must be proximal to the injury site and must be over a bony structure.
- Monitor vital signs continually, record, and report to the health care provider to identify early changes in vital signs indicative of progressing shock.
- Use a blanket to help keep the patient from getting cold; however, the patient also should not be allowed to overheat because this causes peripheral blood vessels to dilate, which draws blood away from vital organs.
- Monitor IV fluids as ordered to increase circulating volume (IV fluid contraindicated in cardiogenic shock).

![Arterial pressure points to control bleeding.](FIGURE 13.3)
Risk for Allergy Response related to exaggerated immune response to substances

**Expected Outcome:** The patient will implement plan to treat allergic reaction.

- Administer epinephrine (Adrenalin) intramuscularly (IM) in the vastus lateralis muscle (preferred because it provides better absorption to work faster) with a 22-gauge, 1- to 1.5-inch needle, or subcutaneously as ordered to suppress the immune system and alleviate allergy symptoms.
- Seek immediate medical attention because effects of epinephrine are temporary.

**Nursing Care Tip**
- Epinephrine is given IM and should not be given IV for anaphylaxis (allergy symptoms with ABC involvement).
- Give antihistamines as second-line therapy as ordered to control the allergic rash and pruritus.
- Steroids are given in gradually tapered doses to prevent return of symptoms.

Ineffective Airway Clearance related to allergic airways

**Expected Outcome:** The patient will maintain a patent airway and clear breath sounds at all times.

- Monitor breath sounds to detect abnormal sounds such as wheezing.
- Administer oxygen as ordered to maintain the pulse oximetry at 95% or greater.
- Position patient upright for optimal respiration to allow maximal lung expansion.
- Encourage patient to breathe deep and cough to clear airways.

**Evaluation**

If interventions have been effective, the blood pressure will improve to within normal limits for the patient and the patient will demonstrate a strong pulse; warm, dry skin; and be less anxious. The patient should show an immediate reversal of shock symptoms. Breathing becomes easy, and blood pressure and pulse return to the normal range. Breath sounds become clear, and hives and pruritus subside.

**Major Trauma**

Accidents or unintentional injury were the fifth leading cause of death in the United States in 2011 according to the Centers for Disease Control and Prevention (CDC), mainly affecting persons under age 34 and over 70. Victims of major trauma might receive injury to an isolated vital organ or to multiple body systems.

**Mechanism of Injury**

When assessing a victim of major trauma, it is important to determine the mechanism of injury (see “Gerontological Issues”). Injuries are classified as either penetrating or

**Gerontological Issues**

**Injuries and Older Adults**

Older adults are at a high risk for falls that put them at risk for bruises, abrasions, cuts, and fractures. Nurses who initially assess older adults with injuries requiring treatment must ask questions and perform assessments that would identify if the patient is a victim of abuse or neglect.

Remember that the resolution of injuries occurs in a longer timeframe in the older patient when compared with the same injury resolution in a younger patient.

**Injuries Caused by Falls Versus Battery or Assault**

Any unexplained bruises, burns, abrasions, cuts, fractures, evidence of old injuries or bruises, burns, and cuts that are in different stages of healing suggest abuse. The pattern of an injury can also suggest abuse—for example, cigarette burns in areas covered with clothing; bruises or friction burns in a ring around the neck, ankles, or wrists; welts, burns, or bruises in the outline of a hand or belt buckle; multiple similar injuries in an area, such as whip marks across the buttocks or back of the legs; defensive injury pattern of bruising; and trauma to the hands and forearms.

Injuries related to falls have a predictable injury pattern related to the history and report of the fall. When an older adult falls, there is bruising of the hands and knees caused when the person attempts to break the fall. Additional bruising or injuries to the front of the body, arms, and head could be caused by hitting furniture or other items during the fall. Skin tears on the arms are common with a fall. Often, a friend or family member sees the older adult starting to fall and tries to steady the person by grabbing the area, tearing the skin. Ask questions to be sure that the report of the fall incident is consistent with the presenting injuries.

Any form of abuse or suspicion of abuse must be reported to the state agency that investigates reports of suspected abuse. It is not the nurse’s responsibility to prove that there has been abuse or neglect, only to report incidents or cases of possible abuse.
blunt. Penetrating, or open, injuries can be caused by a sharp object, such as broken glass or a knife, or by projectiles traveling at high speed, such as bullets or fragments from an explosion. In blunt, or closed, injuries, the skin surface is intact. An injury from blunt trauma usually extends beyond the point of impact to surrounding and underlying structures. For example, a blow to the chest can cause a fracture of several ribs that can, in turn, cause blunt trauma (such as a laceration or hematoma) to the spleen.

Damage caused by a gunshot wound and the trajectory of the bullet depends on the projectile mass, the type of tissue struck, the striking velocity, and the range. Entrance wounds are round or oval and can be surrounded by a rim of abrasion. Powder burns are visible if the firearm was discharged at close range. Documentation of these wounds should include a clear description of their appearance but should not include the words entry or exit because this is determined by trained experts. Patients with gunshot wounds near the level of the diaphragm should be evaluated for both abdominal and thoracic injuries.

**Surface Trauma**

Surface trauma includes any injury that does not break the skin (closed wound) and any open wound in which the skin surface is broken. Types of closed wounds include contusions (bruising) and hematomas (collection of blood under the skin). Types of open wounds include abrasions, punctures, lacerations, avulsions, and amputations.

**Abrasions** are a scraping away of the epidermal and dermal layers of the skin. They bleed very little but can be extremely painful because of inflamed nerve endings. Dirt can be ground into abrasions and can increase the risk of infection when large areas of skin are involved.

**Puncture wounds** result from sharp, narrow objects such as knives, nails, or high-velocity bullets. They can often be deceptive because the entrance wound can be small with little or no bleeding. It is difficult to estimate the extent of damage to underlying tissues as a result. Puncture wounds usually do not bleed profusely unless they are located in the chest or abdomen.

**Lacerations** are open wounds resulting from snagging or tearing of tissue. Skin tissue can be partly or completely torn away. They vary in depth and can be irregular in shape. Lacerations can cause significant bleeding if blood vessels or arteries are involved.

**Avulsions** involve a full-thickness skin loss in which wound edges cannot be approximated. This type of injury is often seen in machine operators or in lawn-mower and power-tool accidents.

**An amputation** is a partial or complete severing of a body part. In cases of complete amputation, the arteries usually spasm and retract into the tissue, resulting in less bleeding than does a partial amputation, in which the lacerated arteries continue to bleed.

If the patient has sustained an amputation, bleeding is controlled with direct pressure and elevation. A tourniquet is applied only as a last resort. If a tourniquet is needed, it should be made of wide material such as a blood pressure cuff, which is less damaging to nerves and blood vessels. A dressing is applied to the amputated extremity, which is referred to as the stump. The stump is covered with sterile saline–moistened gauze followed by dry gauze, which is held in place with an elastic bandage for pressure. Amputated parts are taken to the hospital with the patient for possible reattachment. At the hospital, the amputated part is rinsed with saline solution, wrapped in sterile gauze, and placed in a sealed plastic bag, which is then placed on ice (not covered with ice or in ice water). The goal is to keep the body part cool without causing further damage from cold ice.

For a patient impaled by an object, it is imperative that the object not be removed unless it is obstructing the airway. Removing an impaled object can cause additional trauma and uncontrollable internal bleeding. Impaled objects are never cut off, broken off, or shortened unless transportation to the ED is otherwise impossible. A bulky dressing is applied around the object to stabilize it and reduce motion.

**Tetanus**

**Tetanus** is a disease caused by the bacillus *Clostridium tetani*, which enters the body through an open wound. Tetanus causes seizures, muscle spasms, stiffness of the jaw, coma, and death. Tetanus vaccinations should begin at 2 months of age and be followed by a series of pediatric immunizations until age 15. Thereafter, booster vaccinations are recommended every 10 years in the absence of an open wound.

**Head Trauma**

Sharp blows to the head can cause shifting of intracranial contents and lead to brain tissue contusion. The pathophysiology of head trauma can be divided into two phases. The first phase is the initial injury that occurs at the time of the accident and cannot be reversed. The second phase involves intracerebral bleeding and edema from the initial injury, which causes increased intracranial pressure (ICP). Management of head trauma is directed at the second phase and involves decreasing ICP. Early and late signs and symptoms of ICP are listed in Box 13-4.

**Spinal Trauma**

Spinal cord injury most often results from motor vehicle crashes, sports injuries, falls, and assaults, with most cases occurring in men ages 16 to 30. The cervical spine is especially vulnerable to traumatic injury. Patients who have sustained severe multiple injuries should be suspected of having a spinal cord injury, especially when they have signs of head trauma. All trauma patients should be treated as though they have a spinal cord injury until proven otherwise. Moving a patient with a vertebral injury can cause displacement of the injured bones and can increase damage to the spinal cord. Patients should be moved only by qualified people. Stabilization of the neck and back with a cervical collar and backboard is essential until spinal cord injury is ruled out (Fig. 13.4).
leaking into the intrapleural space collapses the lung, resulting in a pneumothorax (air) or hemothorax (blood) and ineffective ventilation. In a tension pneumothorax, air is trapped in the pleural space during exhalation, resulting in increased pressure on the unaffected lung. The heart, great vessels, and trachea shift toward the unaffected side of the chest. As a result, blood flow to and from the heart is greatly reduced, causing a decrease in cardiac output. An uncorrected tension pneumothorax is fatal.

Chest trauma can also injure the heart and great vessels and reduce the amount of circulating blood volume. The heart can be bruised (myocardial contusion) or can sustain direct trauma. Cardiac tamponade occurs when blood accumulates in the pericardial sac and increases pressure around the heart. The increased pericardial pressure prevents the heart chambers from filling and contracting effectively. A patient with cardiac tamponade will have hypotension, tachycardia (rapid heart rate), and neck vein distention and requires immediate intervention to reduce the pressure in the pericardial sac and restore normal filling and contraction of the heart chambers.

**Abdominal Trauma**

The organs of the abdomen are vulnerable to injury because there is limited bony protection. Injury to organs such as the spleen and liver, which have a rich blood supply, can result in rapid loss of blood volume and hypovolemic shock. Abdominal organs can be injured as a result of severe blunt or penetrating trauma. If hypotension is present, intra-abdominal hemorrhage can exist. If the urinary bladder ruptures, urine leaks into the abdomen and blood can be detected at the urinary meatus or perineum. Penetrating trauma can cause lacerations to abdominal organs, resulting in rapid blood loss and hypovolemic shock.

**Orthopedic Trauma**

Fractured bones can result in blood loss, compromised circulation, infection, and immobility. Unstable pelvic fractures can cause injury to the genitourinary system or disrupt pelvic veins. Fractures of large bones such as the femur and tibia can cause significant blood loss. For example, a fractured femur can cause up to 1500 mL of blood loss, and a fractured tibia or humerus can cause up to 750 mL of blood loss. Joint dislocations can cause neurovascular compromise by applying pressure to the nerves and blood vessels. Delayed fracture reduction (realignment or setting) can cause avascular necrosis, which leads to death of the affected tissue and bone.
Nursing Process for the Patient Experiencing Trauma

Data Collection

The mechanism of injury is determined to identify the extent of injury. Loss of consciousness immediately after an injury indicates that a concussion has occurred. The Glasgow Coma Scale (GCS) is used to rate a patient’s level of consciousness (Fig. 13.5). The highest score is 15, indicating that the patient is alert and needs only observation. Scores lower than 13 can indicate the need for immediate treatment. It is important that nurses be adequately trained in using the scale and that all members of the health care team are consistent in their assessments. Morbidity and mortality are highest for patients with GCS scores of 8 or lower. Pupil size and reaction are monitored and recorded. Dilated or nonreactive pupils indicate increased ICP and a need for immediate intervention. Movement of extremities should also be assessed and documented. Posturing and differences between limb movement on the right and left side can indicate increased ICP.

Spinal nerves are located in the spinal cord and transmit sensory impulses to the brain and motor impulses to the body. The higher a traumatic lesion is on the spinal column, the more extensive will be the loss of muscle and sensory function (Table 13.3). A spinal cord injury at the level of C5 or above interferes with diaphragm function and respiratory effort, which must be carefully assessed. The patient’s level of muscle control and ability to feel each limb are noted and recorded.

Patients with major chest injuries can have dramatic symptoms, including classic signs of shock with cyanosis, dyspnea, and restlessness. The patient’s breathing pattern and effectiveness of respirations are assessed. The rise and fall of the chest is observed, as well as symmetrical chest movement. Any bruising on the chest or upper abdomen is noted. Seat belts and restraint systems can cause significant bruising in high-impact crashes.

Vital signs are taken to detect tachycardia and hypotension from shock. The shape of the abdomen is observed to detect distention from intra-abdominal hemorrhage. Skin color, bruising, open wounds, and penetrating trauma are noted. The abdomen is auscultated for bowel sounds. The perineum is inspected for blood from the urethra.

Vital signs and pain level are assessed to detect orthopedic abnormalities. A respiratory assessment is done to detect a pulmonary embolism as a result of a long bone fracture. The injured extremity is inspected, and skin color and capillary refill time are noted. Skin integrity, protruding bone, or deformity is noted. Pulses distal to the injury are palpated to assess circulation to the area distal to the injury. Motor function and sensation are assessed to determine the extent of nerve injury.

Nursing Diagnoses, Planning, and Implementation

**Acute Pain related to tissue trauma**

*Expected Outcome* The patient will experience relief after measures are provided to relieve pain as evidenced by verbal and nonverbal expressions of pain relief.

- Apply ice, elevate, and immobilize the affected area to decrease swelling and relieve pain.
- Provide analgesics as ordered to relieve pain.

**Impaired Skin Integrity related to tissue trauma**

*Expected Outcome* The patient will demonstrate healing of impaired tissue.

- Apply direct pressure to open wounds to control bleeding.
- Irrigate open wounds with sterile saline solution to thoroughly remove dirt and debris and clean exposed tissue to prevent infection.
UNIT TWO Understanding Health and Illness

Risk for Infection related to tissue trauma

**EXPECTED OUTCOME:** The patient’s wounds will remain free of infection.

- With open wounds, give tetanus immunization as ordered if it has been more than 5 years since one was last given to prevent tetanus infection.
- Give antibiotics as ordered to prevent infection.

Risk for Ineffective Cerebral Tissue Perfusion related to cerebral edema

**EXPECTED OUTCOME:** The patient will maintain adequate cerebral homeostasis without cerebral edema as evidenced by a GCS score of 14 or greater.

- Give oxygen as ordered to maintain adequate oxygenation of brain tissues and prevent cellular damage from hypoxia at the cerebral level.
- If the patient has an altered level of consciousness or deteriorating respiratory effort, anticipate and assist with endotracheal intubation as needed to provide respiratory support to patient.
- Elevate the head of the patient’s bed 30 to 45 degrees, if possible, to reduce ICP.
- Maintain the patient’s head position at midline to ensure unobstructed venous drainage to help reduce ICP.
- Maintain IV access for fluids to maintain hemodynamic stability and access for medications.
- Monitor mannitol IV, an osmotic diuretic, or hypertonic saline (1.7%–29.2%) as ordered to decrease cerebral edema.
- If the patient is agitated, provide calming measures because agitation increases ICP.

Ineffective Breathing Pattern related to neck injury or unstable chest wall segment or lung collapse

**EXPECTED OUTCOME:** The patient will maintain effective respiratory rate and experience improved gas exchange in the lungs.

- If signs of respiratory distress are present, use the jaw-thrust or chin-lift maneuver, along with suction and airway adjuncts as needed, to maintain patency of the airway.
- Maintain cervical collar and backboard to prevent further injury.
- Give oxygen as ordered to improve tissue oxygenation. Advanced adjunct airway equipment, including an endotracheal tube, must be readily available.
- Administer supplemental oxygen as ordered to promote tissue oxygenation.
- Maintain chest tube drainage system if inserted to help expand lung.

Ineffective Airway Clearance related to neck injury

**EXPECTED OUTCOME:** The patient will maintain clear lung sounds.

- Suction the oropharynx and nasopharynx to clear secretions and prevent aspiration of secretions into the airway.
- If the patient vomits, log roll the patient onto one side and use suction as needed to prevent aspiration of emesis.

Impaired Physical Mobility related to neck injury

**EXPECTED OUTCOME:** The patient will maintain movement of extremities normal for patient.

- Maintain neck immobility during initial treatment of a patient with head or neck trauma to prevent serious injury until trauma damage is identified.

Decreased Cardiac Output related to compression of heart and great vessels

**EXPECTED OUTCOME:** The patient will maintain vital signs within baseline limits.

- Report unstable vital signs to physician because patient may need immediate surgical intervention in the operating room.
- Explain diagnostic testing to patients with stable vital signs if radiographic studies are ordered to determine the extent of cardiac or pulmonary injury.
- Monitor patient’s vital signs and oxygen saturation continuously to detect signs of shock.

Deficient Fluid Volume related to hemorrhage or abdominal organ injury

**EXPECTED OUTCOME:** The patient will maintain vital signs within baseline limits.

- Monitor for signs of shock to detect hypovolemic shock.
- Maintain IV fluids as ordered by 18- or 16-gauge IV canulas to restore circulating volume.
- Assist with peritoneal lavage, if performed, to detect intra-abdominal hemorrhage.
- Maintain nasogastric tube, if ordered, to decompress the stomach.
- Cover abdominal wounds with a sterile dressing to prevent infection.
- If abdominal organs are exposed, cover with sterile saline-soaked dressings to prevent tissue necrosis.
- Assist with blood and blood product administration, as ordered and per agency policy, to maintain circulating volume and improve tissue oxygenation.

Impaired Physical Mobility related to bone injury

**EXPECTED OUTCOME:** The patient will maintain movement of extremities normal for patient.

- Remove all jewelry before applying a splint because the extremity can swell after injury.
- Maintain extremity in a splint in the position found, unless distal circulation is severely compromised, and keep it immobilized if there is severe pain or deformity. Splinting promotes comfort and prevents further damage to surrounding tissue by preventing movement of broken bone ends.
- Immobilize the joints above and below the affected area using a folded towel or a pillow to provide comfort and protection until the patient is evaluated by a health care provider.
• Monitor skin color, temperature, distal pulses, capillary refill, movement, and sensation of the extremity after splint application to detect abnormalities.
• Elevate and ice extremity to reduce edema and relieve pain.

**Evaluation**

If interventions have been effective, the following results will be evident: A patient with trauma reports an acceptable pain level, and the patient’s wound heals without infection; a patient with spinal injury maintains a regular rate, rhythm, and pattern of breathing, clear lung sounds, intactness of mobility, and GCS score of 14 to 15; a patient with chest trauma maintains an open airway and effective breathing pattern; a patient with abdominal trauma has effective circulating volume as evidenced by vital signs within normal limits; a patient with orthopedic trauma has strong and palpable pulses, normal blood pressure, normal skin color, skin that is warm and dry, capillary refill time of less than 3 seconds, pain controlled to a satisfactory level, and normal motor function and sensation in the extremity.

**BURNS**

The skin protects the body by preventing bacterial or viral invasion, enhancing temperature regulation, and conserving body fluids and electrolytes. These functions are impaired with a burn injury and can lead to multisystem alterations. Burn injuries are acutely painful and can be dramatic in appearance. Nursing care depends on the extent and depth of the burn injury and the presence of any associated factors, such as smoke inhalation, blunt trauma, or fractures. The more extensive the burn injury, the greater the potential for complications and mortality. The patient’s age can contribute to the risk of mortality as well. Infants younger than age 2 and adult patients older than age 60 have the highest mortality rates from major burns. (See Chapter 55 for more on burns.)

Assessment of the burn patient begins with the ABCDs of the primary survey with exposure E and F, fluid resuscitation added to the secondary survey of burned patients. The history should include the mechanism and time of the injury and a description of the surrounding environment, including the presence of noxious chemicals and inhalation of smoke in an enclosed space. The greatest threat to life in a patient with a major burn injury is smoke or heat inhalation, which causes edema in the respiratory passages. Continuous assessment of respiratory status is essential when you observe burns or soot on the face, singed nasal hairs, a hoarse voice, coughing, or restlessness.

Burns of the face can swell rapidly and can compromise the airway. Facial burns are treated by elevating the head of the bed to 30 degrees to minimize edema. Oxygen is administered to the patient with potential pulmonary injury. Equipment for endotracheal intubation should be readily available. Because large fluid losses occur in burn injuries, an IV infusion with large-bore cannulas should be started. The patient’s weight and the extent of the burn determine fluid resuscitation needs. The patient is kept warm because when skin is lost, a burn victim cannot maintain body heat. IV opioids are administered for pain.

Burn depth is described as superficial, partial thickness, or full thickness (Fig. 13.6). **Superficial burns** are confined to the epidermis. **Partial-thickness burns** are either superficial dermal (epidermis and upper dermis of the skin) or deep (entire epidermal layer and deep dermis; Fig. 13.7). **Full-thickness burns** involve destruction of all layers of the epidermis and dermis and can include muscle, fascia, and bone. Partial-thickness burns that involve a small area are cleaned with sterile saline solution, covered with a 1/8-inch layer of an anti-infective cream such as silver sulfadiazine (Silvadene, Flamazine), and then covered with dry, bulky, fluffed dressings. Major full-thickness wounds are covered with dry, sterile dressings or linen. Patients with major burns are transferred to a specialized burn unit.
environment through conduction, convection, radiation, and evaporation. Heat loss is inversely proportional to body size and body fat. Fat insulates because it has less blood flow and consequently has less ability to vasodilate and lose heat.

Hypothermia occurs when the core body temperature falls below 95°F (35°C). As the core temperature falls below 95°F, the body is less able to regulate its temperature and generate body heat, causing progressive loss of body heat to occur.

Nursing Process for the Patient With Hypothermia

**Data Collection**

In cases of mild hypothermia (core temperature between 90° and 95°F [32.2° and 35°C]), the patient is usually alert, shivering, and can appear clumsy, apathetic, or irritable (Table 13.4). Hypoglycemia can occur because glucose and glycogen stores are depleted by long-term shivering. Respiratory rate, heart rate, and cardiac output decrease.

**Outcome Criteria**

- Core body temperature is greater than 95°F (35°C).
- Patient is alert and oriented.
- Cardiac dysrhythmias are absent.
- Acid–base balance is normal.
- Pupils react normally.
More severe hypothermia occurs between 85° and 90°F (29.4° and 32.2°C). Shivering stops and muscle activity decreases. Initially, fine muscle coordination ceases. Then, as core body temperature continues to drop, all muscle activity stops and the muscles become rigid. The patient becomes lethargic and less interested in fighting the cold environment. The patient’s level of consciousness begins to markedly decrease at 89.6°F (32°C); the patient becomes lethargic and disoriented and begins to hallucinate. The pupils become dilated. As the core body temperature falls to 82°F (27.8°C), the patient becomes apneic, the pulse becomes slower and weaker, and cardiac dysrhythmias occur. The profoundly hypothermic patient has a core temperature of less than 80°F (26.7°C) and usually appears dead, with no obtainable vital signs. Determination of death should be made only after aggressive core rewarming to at least 90°F (32.2°C).

**Nursing Diagnoses, Planning, and Implementation**

Initial treatment of the hypothermic patient consists of rewarming the patient, stabilizing vital functions, and preventing further heat loss (see the “Nursing Care Plan for the Patient With Hypothermia”). The patient is removed from the cold environment. All wet clothing is removed to prevent further heat loss. The patient’s core body temperature guides treatment. If body temperature is above 82.4°F (28°C), passive rewarming is preferred. The room temperature is set to 70° to 75°F (21.1°–23.9°C). The patient’s core body temperature is monitored using a rectal probe. Heated peritoneal lavage, or cardiopulmonary bypass can be performed for profound hypothermia. Cardiac drugs are given sparingly because, as the body warms, peripheral vasodilation occurs. Drugs that were trapped in the peripheral circulation are then suddenly released during rewarming, leading to a bolus effect that can cause fatal dysrhythmias.

**Evaluation**

Desired outcome criteria for the patient with hypothermia is a core body temperature higher than 95°F (35°C), no cardiac dysrhythmias, pulse and blood pressure within normal limits, and an alert and oriented status.

**FROSTBITE**

The extremities are vulnerable to cold injury. Frostnip occurs when exposed parts of the body become very cold but not frozen. This condition usually is not painful. The skin becomes pale and blanched. Contact with a warm object such as someone’s hand can be all that is needed to rearm the part. During rewarming, the affected part might tingle and become red.

Frostbite occurs when body parts become frozen. The extremities are at increased risk because blood shunts away from them to maintain core body temperature. The affected tissue feels hard and frozen. Most frostbitten parts are white, yellow-white, or blue-white. When rewarmed, the skin appears deep red, hot, and dry to touch. The severity of a cold injury is determined by the duration of the exposure, the temperature to which the body part was exposed, and the wind velocity during exposure.

Interventions for frostbite include protecting the affected area from further trauma. To prevent additional damage, the frostbitten part is handled gently and never rubbed. The injured part is loosely covered with a dry, sterile dressing. The patient is not allowed to stand or walk on a frostbitten foot. The affected extremity is elevated to heart level to minimize edema and promote blood flow.

**NURSING CARE PLAN** for the Patient With Hypothermia

**Nursing Diagnosis:** *Hypothermia* related to exposure to cold environment

**Expected Outcomes:** The patient’s body temperature and vital signs will be within normal limits.

**Evaluation of Outcomes:** Is patient’s body temperature greater than 95°F (35°C)? Is patient alert and oriented? Is cardiac rhythm normal?

**Intervention** Monitor patient’s core body temperature. **Rationale** Abnormal body temperature can be detected and treated. **Evaluation** Is body temperature greater than 95°F (35°C)?

**Intervention** Monitor pulse and electrocardiogram (ECG) rhythm. **Rationale** Cardiac dysrhythmias can occur at temperatures below 91.4°F (33°C). **Evaluation** Is pulse rate and ECG rhythm normal?

**Intervention** Monitor patient’s level of consciousness. **Rationale** Level of consciousness becomes markedly decreased at temperatures of 89.6°F (32°C). **Evaluation** Is the patient alert?

**Intervention** Institute rewarming passively or actively as ordered. **Rationale** Rewarming is necessary to return body temperature to desirable range. **Evaluation** Is body core temperature rising to normal range?
Hyperthermia results when thermoregulation breaks down because of excess heat generation, an inability to dissipate heat, overwhelming environmental heat, or a combination of these factors. Unlike a fever, in which the thermal set point is elevated, in heat illness the thermal set point remains normal and hyperthermia occurs because of an inability to dissipate heat. Antipyretics are of no use in hyperthermia and can contribute to complications.

### Nursing Process for the Patient With Hyperthermia

**Data Collection**

Illness from heat exposure can take three forms: heat cramps, heat exhaustion, and heatstroke (Box 13-5). As heat illness progresses, circulating blood volume decreases, causing dehydration. Fluid intake is crucial in the prevention of heat illness.

**Heat Cramps.** Heat cramps, the mildest form of heat illness, involve painful muscle spasms, usually in the legs or abdomen, that occur after strenuous exercise. Large amounts of salt and water can be lost as a result of excessive sweating, causing stressed muscles to spasm. With adequate rest and fluid replacement, the body adjusts the distribution of electrolytes and the cramps disappear.

**Heat Exhaustion.** Heat exhaustion occurs when the body loses so much water and electrolytes through heavy sweating that hypovolemia occurs. Heat exhaustion is largely a manifestation of the strain placed on the cardiovascular system as it tries to maintain normothermia. Cerebral function is unimpaired, although the patient can show minor irritability and poor judgment. The ability to sweat remains. The skin is usually cold and clammy and the face gray. Sodium and water loss cause the patient to become dehydrated. The body temperature is usually normal or slightly elevated: from 100.4°F (38.0°C) to 102.2°F (39.0°C). The patient might report feeling dizzy, weak, or faint, with nausea or a headache. Vomiting and diarrhea can also be present.

**Heatstroke.** If symptoms of heat exhaustion are not treated, heatstroke can develop. Altered mental status and an inability to sweat are key symptoms in heatstroke. Some patients show confusion, irrational behavior, or psychosis; others develop seizures or go into a coma. Because the sweating mechanism has been overwhelmed, many heatstroke victims have hot, dry, flushed skin. The body temperature rises rapidly to 106°F (41.1°C) or higher and level of consciousness decreases. If heatstroke is not treated, death results.

Patients with heatstroke are admitted to the intensive care unit because late complications can appear suddenly and require immediate management. Relatedly common occurrences include seizures, cerebral ischemia, renal failure, late cardiac decompensation, and gastrointestinal (GI) bleeding. Long-term prognosis varies with the patient’s previous state of health and length of time under heat stress.

### BE SAFE!

**BE VIGILANT!** Older adults are vulnerable to hyperthermia. In times of extreme summer temperatures, older people who live alone should be checked to make sure they are not experiencing hyperthermia. If they do not have fans or air-conditioning available, they should be taken to a cooler environment.
Chapter 13  Nursing Care of Patients With Emergent Conditions and Disaster/Bioterrorism Response 251

Nursing Diagnoses, Planning, and Implementation

Hyperthermia related to exposure to hot environment

**EXPECTED OUTCOME:** The patient will maintain body temperature within normal limits.

- For heat cramps, remove the patient from the hot environment to allow cooling to begin.
- Have patient sit or lie down until muscle cramps subside to prevent further injury.
- Remove patient from the hot environment and undress patient to allow patient to cool rapidly.
- Mist-spray tepid water over the patient while maintaining a strong continual breeze from electric fans because evaporative cooling is the most efficient method of cooling.

Deficient Fluid Volume related to hypovolemia

**EXPECTED OUTCOME:** The patient will maintain blood pressure within normal limits of baseline.

- Give patient oral fluids, water, or a diluted (half-strength) balanced electrolyte solution if patient is fully alert to replace lost fluids.
- If patient is hypotensive, maintain IV fluids as ordered to restore volume.

**Evaluation**

Interventions have been successful if the hyperthermic patient has a core body temperature below 101°F (38.3°C), warm and dry skin, a strong pulse, blood pressure within normal limits, and is alert and oriented.

**POISONING AND DRUG OVERDOSE**

Poisons are introduced into the body by ingestion, inhalation, injection, absorption, or venomous bites. Poisons act by changing cellular metabolism, causing damage to structures, or disturbing function. Many toxins and poisons alter the patient’s mental status, making it difficult to obtain an accurate history.

**Nursing Process for the Patient With Ingested Poisoning**

**Data Collection**

The primary nursing responsibility is to recognize that a poisoning has occurred and then try to determine the nature of the poison. The method of exposure is established so that removal or interruption of the toxin can begin. Most ingested poisons are drugs, but about one-third of poisonings are caused by cleaners, soaps, insecticides, acids, or alkalis. Many household plants are poisonous if they are accidentally ingested. Some plants cause local irritation of the skin, and others can affect the circulatory system, GI tract, or central nervous system.

Empty medication bottles, scattered pills, and relevant chemicals should be examined by emergency medical personnel at the scene to help identify the poisonous substance. The patient’s physical appearance also can give a clue to the type of substance ingested. IV needle tracks, burns, erythema, and flushed skin can help identify the poison or toxic exposure.

**NURSING CARE TIP**

- Syrup of ipecac is NOT recommended for at-home treatment of accidental overdose because evidence shows that its use does not improve patient outcomes. For example, giving it to a person who had swallowed a caustic chemical results in greater tissue damage from the vomiting of the chemical, or after being given syrup of ipecac, a person who was poisoned may vomit the necessary antidote.
- Gastric decontamination, activated charcoal, and gastric lavage are no longer routinely recommended and should be reserved for the most severe cases.

**Inhaled Poisons**

Inhaled poisons include natural gas, pesticides, carbon monoxide, chlorine, and other gases. Carbon monoxide is odorless and can produce profound hypoxia by combining with hemoglobin molecules and displacing oxygen in red blood cells. The patient’s carboxyhemoglobin level is monitored to direct appropriate therapy. Inhalation of chlorine is irritating to the respiratory system and can produce airway obstruction and pulmonary edema.

When an inhalation injury from a poison occurs, the patient must be moved into fresh air and away from the toxin. Supplemental oxygen is given as ordered. A patient exposed to prolonged inhalation of a poison can experience lung damage. Respiratory status must be closely monitored to detect complications.

**Injected Poisons**

Injected poisons pose compelling problems because they are difficult to remove or dilute. Usually the result from drug overdose, but they can also result from the bites and stings of insects or animals. Local swelling and tissue destruction can
occur at the injection site. All jewelry is removed because swelling can occur. A cold pack is applied to decrease local pain and swelling around the injection site. The identity of the injected drug or toxin must be established so that adverse effects can be anticipated and managed.

**Snakebites**

Only a small percentage of snakebites are caused by poisonous snakes. The most prevalent poisonous snakes are the coral snake and the pit vipers, which include rattlesnakes, copperheads, and cottonmouth moccasins. Envenomation occurs when the snake’s hollow fangs puncture the skin and inject venom, which is stored in sacs located at the back of the snake’s head. A poisonous snakebite leaves two small puncture wounds with surrounding discoloration, swelling, and pain. Envenomation by any of the pit viper snakes produces burning pain at the site of the injury. Swelling and discoloration occur within 5 to 10 minutes after the bite.

Interventions are focused on decreasing the circulation of venom throughout the patient’s system by keeping the patient calm and immobilizing the affected part. The affected extremity should be positioned below the level of the heart. The site of the bite is cleaned with soap and water but should not be irrigated or flushed. The wound should be covered with loose, clean dressing. Ice should not be applied to the bite. The patient is kept calm until antivenin can be given. Medical treatment of the patient with a poisonous snakebite should be directed by an experienced toxicologist.

**Near-Drowning**

Drowning is death from asphyxia (insufficient oxygen intake) after submersion in water. Near-drowning is used to describe submersion with at least temporary survival of the victim. Life-threatening complications of near-drowning are respiratory failure and ischemic neurologic injury from hypoxia and acidosis. When submersion occurs, conscious victims hold their breath until reflex inspiratory efforts override breath holding. As water is aspirated, laryngospasm occurs, producing severe hypoxia. In wet drowning, the laryngospasm is less prolonged and fluid enters the lungs after the vocal cords relax. In dry drowning, cold water causes laryngospasm and vagal stimulation, which leads to asphyxiation. Most successfully resuscitated victims experience dry drowning. Risk factors for drowning include inability to swim, diving accidents, use of alcohol and drugs before swimming, exhaustion, and hypothermia.

If a person survives submersion, acute respiratory failure can follow. The incidence of serious pulmonary complications is high in this group. Symptoms of impaired gas exchange (known as secondary near-drowning) can be delayed as long as 72 hours after the incident. Contaminants in the water can irritate the pulmonary system and cause inflammatory reactions and impaired surfactant functioning. Metabolic acidosis is usually present, leading to tissue anoxia and dysrythmias. Hypoxemia and hypothermia predispose the patient to arrhythmias. Neurologically, there is neuronal damage and cerebral edema.

Aggressive resuscitative efforts should be used on victims of cold-water drowning when submersion time is 1 hour or less. Hypothermia can decrease the metabolic needs of the brain and contribute to neurologic recovery even after prolonged submersion. Resuscitation should not be stopped until the body temperature is at least greater than 32°C.

**Nursing Process for the Near-Drowning Patient**

**Data Collection**

Most near-drowning victims have mild dyspnea, a deathlike appearance with blue or gray skin color, apnea or tachypnea (abnormally fast breathing), hypotension, slow heart rate (possibly less than 10 beats per minute), cold skin temperature, dilated pupils, hypothermia, and vomiting. Vital
signs are assessed to detect abnormal readings. Respiratory rate and pattern are observed. Any dyspnea or signs of airway obstruction are noted. Skin color or cyanosis is noted. The patient’s level of consciousness can be altered from anoxia.

Nursing Diagnoses, Planning, and Implementation

Ineffective Tissue Perfusion related to severe anoxia

EXPECTED OUTCOME: The patient will maintain level of consciousness and vital signs within normal range, with clear breath sounds that are equal bilaterally.

- Conduct ABCDs of the primary survey, which always begin resuscitative efforts, to determine patient’s status.
- Give supplemental oxygen as ordered to increase tissue oxygenation.
- Ensure that adjunct airway equipment is available because endotracheal intubation and insertion of a nasogastric tube to decompress the stomach can be needed.

Evaluation

Factors that influence the outcome of near-drowning include the temperature of the water, length of time submerged, cleanliness of the water, and age of the victim. The younger the patient, the better the chance of survival. Interventions have been successful if the patient has normal respiratory rate and pattern and vital signs, is alert and oriented, and skin that is warm and dry to touch with a capillary refill time of less than 3 seconds.

PSYCHIATRIC EMERGENCIES

A psychiatric emergency occurs when a person no longer has the coping skills needed to maintain the usual level of functioning. The patient’s moods, thoughts, or actions can be so disordered that the patient could harm self or others if the situation is not quickly controlled. If acute psychiatric episodes are not managed, they can result in life-threatening, suicidal, violent, or psychologically damaging behavior. If an emotional trauma is not managed successfully, a condition known as posttraumatic stress disorder can result, in which tension, anxiety, guilt, and fear concerning the traumatic event produce cognitive, affective, and behavioral responses to memories of the event long after the event has passed.

A crisis occurs when people enter a sudden state of emotional turmoil and are unable to resolve the situation with their own resources. Common emotional or behavioral manifestations of psychiatric crises include responses to stressful events, anxiety, depression, psychosis, and mania. Anxiety can range in severity from mild to a state of panic. Panic evolves into complete disorganization and loss of control. A patient in panic is terrified and needs external controls to avoid harm.

Depression is an affective disorder most commonly characterized by physical ailments and somatizations. Antidepressants and certain forms of therapy are used to restore the balance of brain neurotransmitters and diminish the symptoms of depression.

Psychotic patients experience impaired thought processes and thought content characterized by hallucinations, delusions, ideas of reference, thought broadcasting, and thought insertion. Psychotic thinking and abnormal speech patterns interfere with the patient’s attempt to communicate rationally.

Manic behavior is most commonly the result of manic-depressive (bipolar) disorder. Manic persons typically exhibit bizarre, extreme, and hyperactive behaviors. Manic persons are also at high risk for injuring themselves or others.

Nursing Process for the Patient With a Psychiatric Emergency

Data Collection

Causes of psychiatric emergency symptoms are varied and require thorough assessment of the patient’s history and mental status. Information from the patient’s medical history can produce possible or panic causes contributing to the patient’s presenting symptoms. Endocrine dysfunction, electrolyte abnormalities, and head trauma are examples of medical conditions that can cause changes in mental status. A medication history is obtained to determine compliance with medication regimens and any recent changes in medications. Information regarding recent use of alcohol or illicit drugs should be obtained because these substances can heighten psychiatric emergencies. A brief mental status examination is conducted. Determining a person’s suicide risk is very important. The patient’s appearance, behavior, cognitive function, thought content, and thought processes are noted. The nurse determines whether the patient is having problems concentrating, following instructions, or recalling his or her medical history.

The nurse’s role is to keep the patient free from harm. To do this, the nurse needs to establish a trusting relationship with the patient. Ways to accomplish this include being respectful and truthful, listening carefully, and providing a safe and calm environment for the patient.

Nursing Diagnoses, Planning, and Implementation

Anxiety related to situational stress

EXPECTED OUTCOME: The patient will state reduced anxiety.

- Establish an atmosphere of trust so the patient feels free to discuss problems.
- Use active listening to acknowledge patient’s physical and emotional concerns.
- Speak directly and truthfully to the patient to gain patient trust, and do not promise unachievable things.
- Trusted supportive members of the patient’s family can be involved to calm the person and encourage cooperation.
- Do not allow bystanders or adversarial family members to visit the patient because they could create further upset for the patient.
- Speak compassionately with the patient and refrain from laughing or joking to show respect for the patient.
Risk for Injury related to impaired judgment

**EXPECTED OUTCOME:** The patient will remain free from injury.

- Do not threaten, challenge, or argue with a disturbed patient to prevent injury.
- Make sure the environment is safe and that external sources of stimulation are reduced to prevent injury.
- Be firm but unthreatening to help patient feel safe.
- Administer antipsychotic medications as ordered, to reduce psychosis, and monitor the patient to determine their effect.
- Follow agency policy for use and documentation of physical restraints, if needed and ordered by health care provider, to ensure patient safety.
- Monitor patient and check pulses and capillary refill after restraints have been applied to prevent patient harm or restriction of circulation.

**Evaluation**

Interventions are successful if the patient reports reduced anxiety and remains free from injury.

---

#### DISASTER RESPONSE

A disaster is defined as any event that overwhelms existing personnel, facilities, equipment, and capabilities of a responding agency, institution, or community. Potential sources of disaster include internal events such as fires and explosions; external events such as floods, storms, fires, earthquakes, and tornadoes; and created events such as motor vehicle accidents, plane crashes, and acts of terrorism.

External disasters involve a community-wide response of several agencies, including emergency medical system (EMS) providers, fire agencies, law enforcement (all first responders), and hospitals. These agencies work together to coordinate search, rescue, transportation, communication, and treatment of multiple victims. Hospitals serve as the major treatment area for victims of a disaster, referred to as casualties who have been injured. When a disaster occurs, the hospital activates its disaster plan, which outlines specific duties for each nursing unit and the staff for each nonnursing department as well. Typically, each nursing unit prepares for the influx of casualties by calling all available off-duty staff to report to work and by discharging noncritical patients. In a hospital disaster plan, each nursing unit is usually designated to receive specific types of casualties, such as major trauma, burns, medical, pediatric, or psychiatric. The ED serves as the triage (sorting for the purpose of assigning priorities) and stabilization area for casualties. To facilitate the triage, stabilization, and transportation of numerous casualties, the hospital disaster plan can assign one or more staff from each nursing unit and each nonnursing department to a specific area or task within the ED, such as first aid, critical care, burn treatment area, family room, or transportation.

During a disaster, decision making and prioritization of patient care are guided by the resources and personnel available. Patients who are seriously injured and have the greatest chance of full recovery are treated first. Each hospital and agency involved in responding to a disaster follows a disaster response plan that outlines the roles and responsibilities of the staff and the procedures to follow when interacting with the media, families, other agencies, and casualties. Disaster drills are conducted on a regular basis to evaluate and rework plans. You should be familiar with your agency’s disaster plans and policies and know your role and responsibilities during a disaster.

---

#### BIOTERRORISM

**Recognition of Potential Bioterrorism Agents**

The CDC evaluates and prioritizes bacteria, viruses, and toxins on their risk for use in a bioterrorism attack (see www.bt.cdc.gov and Table 13.5). As in naturally occurring outbreaks, early recognition of a bioterrorism attack is critical for rapid implementation of preventive measures, treatment, and public health response.

communication. Early recognition can be challenging, however, because patients presenting for medical care after exposure to a biological agent can initially have nonspecific symptoms or symptoms that differ from typical natural infections.

**Smallpox/Variola Major**

Smallpox is caused by the variola virus, an orthopoxvirus unique to humans. This virus is not known to be transmitted by animals or insects. Smallpox was declared eradicated in 1980, three years after the last naturally occurring case was reported. Smallpox is stable and highly infectious in the aerosol form. The risk for a smallpox attack currently is considered low but not zero.

Smallpox has an average fatality rate of 30%. The incubation period is 7 to 17 days. Symptoms of the initial phase include the acute onset of high fever, malaise, headache, backache, and prostration. Other prominent symptoms include vomiting and abdominal pain. The characteristic rash occurs 2 to 3 days later appearing first as small red spots on the tongue and in the mouth. The rash will then appear on the face and extremities and spread to all parts of the body within 24 hours. The rash progresses slowly, from macules to papules to vesicles and pustules and finally to scabs, with each stage lasting 1 to 2 days. The lesions are firm, discrete vesicles or pustules (4–6 mm in diameter) deeply embedded in the dermis. Fever is present throughout the evolution of the rash, which can become painful as pustules enlarge. A second fever spike 5 to 8 days after onset of the rash can signify a secondary bacterial infection. Pustules remain for 5 to 8 days, after which crusting occurs. Pustules are more concentrated on the face and distal limbs than on the trunk and can involve the palms and soles. Scarring occurs with scab separation from destruction of sebaceous glands.

Complications of smallpox include fluid and electrolyte disturbances, extensive skin loss that resembles burns, bronchitis and pneumonitis, blindness due to eye infection, arthritis, and encephalitis.

**Diagnosis**

A suspected case of smallpox is a public health emergency. Local and state health authorities, the hospital epidemiologist, and other members of a hospital response team for biological emergencies should be notified immediately if smallpox is suspected.

The differential diagnosis of smallpox includes other illnesses that can cause fever and a rash. Severe varicella (chickenpox) is the disease most likely to be confused with smallpox. However, familiarity with the clinical features of the two diseases, particularly the rash, should help differentiate them. Additional information that can be useful in differentiating smallpox from chickenpox includes a history of exposure to persons with chickenpox, a personal history of chickenpox, a history of vaccination against varicella or smallpox, and the clinical course of illness.

**Infection Control and Postexposure Isolation**

In the event of a limited outbreak, patients should be admitted to the hospital and confined to rooms that are under negative atmospheric pressure and equipped with high-efficiency particulate air (HEPA) filtration. Standard, contact, and airborne precautions, including use of gloves, gowns, and masks, should be strictly observed. Unvaccinated staff caring for patients suspected of having smallpox should wear fit-tested N95 or higher quality respirators. Patients should wear a surgical mask and be wrapped in a gown or sheet to cover the rash when they are not in a negative-airflow room.

All laundry and waste should be placed in biohazard bags and autoclaved before being laundered or incinerated. Surfaces that can be contaminated with smallpox virus can be decontaminated with disinfectants that are used for standard hospital infection control, such as hypochlorite and quaternary ammonia.

**Anthrax**

Anthrax is a disease caused by the spore-forming bacterium Bacillus anthracis. The organism is found worldwide in soil. Animals become infected through grazing in contaminated areas. Under natural conditions, humans contract the disease after close contact with infected animals or contaminated animal products such as hides, wool, or meat. On exposure to the tissues or blood of an animal or an infected human, the spores germinate.

**Classification and Epidemiology**

Anthrax occurs in three clinical forms in humans: inhalational, cutaneous, and GI. In a biological attack, aerosol exposure to anthrax spores would be most likely. Before 2001, exposure to powdered anthrax spores in an envelope or package was not thought to be an efficient means of causing inhalational disease. However, exposure to anthrax spores sent through the U.S. mail in the 2001 anthrax attack resulted in cases of inhalational anthrax and cutaneous disease.

Cutaneous anthrax is the most likely way to develop anthrax. It results from inoculation of spores subcutaneously through a cut or abrasion. GI and oropharyngeal anthrax occur in rural parts of the world where anthrax is endemic. They result from ingestion of meat contaminated with spores.

**Inhalational Anthrax**

**CLINICAL PRESENTATION AND DIAGNOSIS.** Clinical symptoms develop rapidly after germination of anthrax spores. The incubation period for inhalational disease is most commonly reported as 1 to 6 days but can be prolonged by antibiotic administration.

Inhalational anthrax is a two-stage disease. The initial stage is a nonspecific, flu-like illness lasting from several hours to a few days. The early clinical presentation includes some combination of fever, myalgia, headache, cough, mild chest discomfort, weakness, abdominal pain, and chest pain. Profound malaise, fever, and drenching sweats are prominent symptoms, and nausea and vomiting are frequent. Classically, the initial stage is followed 1 to 3 days later, sometimes after brief improvement, by the rapidly progressive second stage, characterized by fever, dyspnea, diaphoresis, cyanosis, and shock.
There is no rapid screening test to diagnose inhalational anthrax in its early stages. In persons with a compatible clinical illness for whom there is a heightened suspicion of anthrax based on clinical and epidemiological data, the appropriate initial diagnostic tests are a chest x-ray or chest computed tomographic (CT) scan, or both, and culture and smear of peripheral blood. Pleural fluid and cerebrospinal fluid, as well as biopsy specimens taken from the pleura and lung, are also potentially useful for culture and other testing when disease is present in these sites, whereas sputum culture and Gram stain are unlikely to be useful.

**THERAPEUTIC INTERVENTION.** Early IV antibiotic treatment can improve survival in inhalational anthrax. Aggressive supportive care, including attention to fluid, electrolyte, and acid-base disturbances and drainage of pleural effusions, also play an important role in treatment. At present, IV ciprofloxacin or doxycycline plus one or two additional antimicrobials are recommended (CDC, 2008).

**Cutaneous Anthrax**

After an incubation period of approximately 7 days (range: 1–12 days), the primary lesion of cutaneous anthrax appears as a nondescript, painless, pruritic papule, usually on an exposed area such as the face, head, neck, or upper extremity (Fig. 13.8). The papule enlarges and develops a central vesicle or bulla with surrounding brawny, nonpitting edema. The central vesicle enlarges and ulcerates over 1 to 2 days, becoming hemorrhagic, depressed, and necrotic and leading to a central black eschar. Satellite vesicles can be present. The eschar dries and falls off over the next 1 to 2 weeks (Fig. 13.9). Tender regional lymphadenopathy, fever, chills, and fatigue can occur. Systemic disease has been reported to have a mortality of 20% if untreated.

**INFECTION CONTROL.** Person-to-person transmission of anthrax is not known to occur. Patients can be hospitalized in a standard hospital room with standard barrier isolation precautions. No treatment is necessary for persons who come in contact with the patient.

**Plague**

Plague is caused by the Gram-negative coccobacillus *Yersinia pestis*. Under natural conditions, plague is transmitted to humans by the bite of an infectious flea and, less frequently, by direct contact with the infectious body fluids or tissues of an infected animal or by inhaling infectious droplets. Plague has a long history of use and development as a biological weapon. After a biological attack, primary pneumonic plague would be most likely.

**Clinical Presentation**

Plague is a severe febrile illness. Pneumonic plague, the most fatal form of the infection, can develop from inhalation of plague bacilli (primary pneumonic plague).

The incubation period for pneumonic plague is typically 2 to 4 days (range: 1–6 days). Presenting symptoms typically include the acute onset of malaise, high fever, chills, headache, chest discomfort, dyspnea, and cough concomitant with or followed rapidly by clinical sepsis. Hemoptysis is a classic sign that should suggest plague in the appropriate clinical context, but sputum can be watery or purulent. GI symptoms can be prominent with pneumonic plague; these include nausea, vomiting, diarrhea, and abdominal pain. A cervical bubo (swelling of the lymph nodes) is infrequently present. The disease is rapidly progressive, with increasing dyspnea, stridor, and cyanosis. Rapidly progressive respiratory failure and sepsis within 2 to 4 days of onset of illness is typical of pneumonic plague.

**Diagnosis**

During a confirmed outbreak of pneumonic plague after a biological attack, a presumptive diagnosis can be made on the basis of symptoms, especially if there is a high index of
suspicion. However, other causes of severe pneumonia or rapidly progressive respiratory infection with or without sepsis should be considered.

Laboratory findings are consistent with the systemic inflammatory response syndrome. The leukocyte count is elevated and the differential shows a neutrophil predominance, including immature forms. Platelets can be normal or low. Coagulation abnormalities include prolongation of the international normalized ratio (INR), prothrombin time (PT), and partial thromboplastin time (PTT). Elevated liver function tests and abnormal renal function tests are seen with systemic disease.

**Therapeutic Intervention**

When plague is suspected, antibiotic treatment should begin before laboratory confirmation of the diagnosis. Levofloxacin (Levaquin) has been approved by the Food and Drug Administration to treat plague and reduce the risk of plague after exposure.

**Botulism**

Botulism is a paralytic illness caused by a potent neurotoxin produced by *Clostridium botulinum*, an anaerobic, spore-forming bacterium. Natural forms of the disease are foodborne botulism, wound botulism, and infant botulism. Foodborne botulism results from ingestion of improperly processed foodstuffs containing preformed toxin produced by *C. botulinum*. (Botox is the trade name of a toxin made by C. botulinum that is used as a cosmetic treatment to reduce facial aging lines by blocking nerve impulses to the muscles whose action causes the lines). Wound botulism results from production of botulinum toxin by *C. botulinum* organisms that contaminate wounds. Infant botulism results from the colonization of the intestinal tract of infants after ingestion of spores. (Honey can contain the bacteria, so infants under 1 year of age should not eat honey.) Botulinum toxin has been developed as a biological weapon. An aerosol attack is considered the most likely use of botulinum toxin for bioterrorism.

Botulinum toxin is the most potent lethal toxin known. The estimated toxic dose of type A botulinum toxin is 0.001 mcg/kg of body weight. Botulinum toxin acts to block neurotransmission by binding to the presynaptic nerve terminal at the neuromuscular junction and pre venting the release of acetylcholine, resulting in skeletal muscle weakness. The toxin is colorless, odorless, and presumably tasteless.

**Clinical Presentation**

The incubation period for foodborne botulism is 2 hours to 8 days; the typical incubation period is 12 to 72 hours. The incubation period for inhalational botulism has not been established. The neurologic features of botulism are similar. Although initial symptoms in foodborne botulism can include nausea, vomiting, abdominal cramps, and diarrhea, these symptoms are thought to result from other bacterial metabolites in contaminated food and cannot occur in inhalational botulism.

The so-called classic triad of botulism summarizes the clinical presentation: an afebrile patient, symmetrical descending flaccid paralysis with prominent bulbar palsies, and a clear mentation. Patients typically present with difficulty seeing, speaking, or swallowing. Clinical hallmarks include ptosis, blurred vision, and the so-called four Ds: diplopia, dysarthria, dysphonia, and dysphagia. Anticholinergic symptoms are common, including dry mouth, ileus, constipation, nausea and vomiting, urine retention, and mydriasis. Other symptoms include dizziness and sore throat. Sensory findings are not present, with the exception of circumoral and peripheral paresthesias secondary to hyperventilation resulting from anxiety. Botulinum toxin does not cross the blood-brain barrier. Cranial nerve dysfunction and facial nerve weakness can make communication difficult; these symptoms can be mistaken for lethargy and signs of central nervous system involvement.

**Diagnosis**

Treatment with botulinum antitoxin should begin based on the clinical diagnosis and should not wait laboratory confirmation. For potential foodborne botulism, samples of stool, gastric aspirate, emesis, and suspect foods should also be submitted. The possibility of a bioterrorism attack should be considered in any outbreak of botulism. A bioterrorism attack should especially be considered when a cluster of cases occurs, when an outbreak has a common geographical location but there is no common dietary exposure (suggestive of possible aerosol exposure), when there is an outbreak of an unusual botulinum toxin type, or when multiple simultaneous outbreaks occur. A careful dietary and travel history must be taken to help identify the source. Patients should be asked if they know of others with similar symptoms.

**Therapeutic Intervention**

The mainstay of treatment for botulism is supportive care, including intensive care, mechanical ventilation, and parenteral nutrition. Morbidity and mortality are usually from:

- Pulmonary aspiration secondary to loss of the gag reflex and dysphagia leading to inability to control secretions
- Respiratory failure secondary to inadequate tidal volume from diaphragmatic and accessory respiratory muscle paralysis
- Airway obstruction from pharyngeal and upper airway muscle paralysis.

Careful and frequent monitoring of the gag and cough reflexes, swallowing, oxygen saturation, vital capacity, and inspiratory force are critical. Airway intubation is indicated for inability to control secretions and impending respiratory failure. Secondary infections are common and should be sought in patients who develop fever.

Trivalent (ABE) equine antitoxin is available from the CDC through state and local health departments and should be administered as soon as possible after clinical diagnosis. Antitoxin can prevent progression of disease caused by subsequent binding of toxin but does not reverse the effects of
already bound toxin. For this reason, antitoxin is not useful if the patient is no longer showing progression of disease or is improving from maximum paralysis.

**Transmissibility and Infection Control**

Botulism is not transmitted from person to person. Botulinum toxin does not penetrate intact skin. Standard infection-control precautions are adequate. Clothes of persons exposed to an aerosol release of botulinum toxin should be removed and washed. Exposed persons should shower with soap and water. Exposed environmental surfaces can be decontaminated with 0.1% hypochlorite bleach solution.

**SUGGESTED ANSWERS TO**

**CRITICAL THINKING**

- **Mr. Smith**
  1. The airway is the first priority because edema from inhalation burns can occlude the airway.
  2. You know that Mr. Smith is at risk for respiratory burns because of the soot near his mouth and nose. He should be closely monitored. Assessment should include respiratory rate and pattern and the patient’s ability to speak without a hoarse voice. Abnormal breathing sounds such as wheezing indicate partial upper airway occlusion.
  3. The vital signs are within normal limits.
  4. Deep partial-thickness burns should be covered with dry dressings. Because the skin can no longer protect the patient, wet dressings provide a medium for bacterial invasion. Wet dressings can also cause a decrease in body temperature because the skin can no longer maintain thermoregulation.
  5. Jewelry should always be removed immediately, before edema formation begins.
  6. Mr. Smith was involved in an explosive incident and thrown 50 feet. He could have sustained fractures of the pelvis or back. He may also have internal organ injuries from blunt trauma.
  7. The ED health care provider, registered nurse, respiratory therapist.

**REVIEW QUESTIONS**

1. Which of the following assessments would the nurse include in a primary survey of a multisystem trauma victim? **Select all that apply.**
   1. Airway
   2. Breathing
   3. Circulation
   4. Chronic illness
   5. Vital signs
   6. Deformity

2. The nurse is caring for a trauma patient who is hemorrhaging from a puncture wound. Which of the following interventions should the nurse use to control the arterial bleeding?
   1. Pressure at the puncture site
   2. Application of a tourniquet
   3. Pressure-point massage
   4. Pressure dressing

3. The nurse would anticipate the potential for inhalation injury in a patient who was in a house fire with which of the following assessment findings?
   1. Peripheral edema
   2. Singed nasal hairs
   3. Jugular vein distention
   4. Increased capillary refill time

4. Which of the following actions should be taken first for a patient who is found with hyperthermia? **Select all that apply.**
   1. Undress the patient.
   2. Use tepid water as a mist spray.
   3. Remove patient from the hot environment.
   4. Place patient in continual breeze from electric fans.

5. For which of the following should the nurse observe the patient who has inhaled chlorine? **Select all that apply.**
   1. Airway obstruction
   2. Sacral edema
   3. Increased capillary refill time
   4. Unequal pupils
   5. Dyspnea
   6. Pulmonary edema

6. When interacting with a psychotic patient, which of the following interventions is helpful to gain the patient’s trust?
   1. Play along.
   2. Show respect.
   3. Avoid eye contact.
   4. Make promises.
Chapter 13  Nursing Care of Patients With Emergent Conditions and Disaster/Bioterrorism Response

7. Which of the following patients should be treated first in a disaster situation?
   1. A 10-year-old with a closed leg fracture that is painful
   2. A 32-year-old with slight bleeding from a hand laceration
   3. A 45-year-old with an open head injury, no pulse or respirations
   4. A 62-year-old reporting chest pain and shortness of breath

8. Which one of the following would the nurse recognize as an immediate threat to life during acute anaphylaxis?
   1. Hypotension
   2. Generalized itching
   3. Airway obstruction
   4. Tachycardia

9. The nurse is collecting data on a patient who is hypovolemic. Which of the following signs and symptoms indicate that the patient is experiencing progressive shock?
   1. Sacral edema
   2. Jugular vein distention
   3. Decreasing blood pressure
   4. Palpable, bounding pulse

10. The nurse is to give penicillin G 500,000 units IM. The nurse has a 10-mL vial labeled “penicillin 400,000 units/mL.” How many milliliters should the nurse give? Answer: __________ mL

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. List Erikson’s eight stages of psychosocial development.
2. Identify the effects of chronic illness.
3. Describe special needs that caregivers have.
4. Explain health promotion methods.
5. Plan nursing interventions for a patient who is chronically ill.
HEALTH, WELLNESS, AND ILLNESS

Health is much more than just the absence of disease. Have you ever known someone with what appears to be a small health problem who considers himself unwell or disabled, or a person with major health problems who sees himself as well? Many things play a role in a person’s perception of health. One is the ability to function or perform desired or necessary tasks such as activities of daily living (ADL). Another is the ability to fulfill one’s roles, such as student, parent, or employee. The quality of one’s life is another component of health. A person’s ability to adapt to changes in physical, psychological, social, and spiritual aspects of life is considered to plan health care. Wellness is a term used to describe a progression toward a higher level of functioning. Even though a person has a disabling illness, he or she may still be able to achieve a higher level of wellness.

NURSING CARE TIP
To foster understanding of how an ill patient, especially an older patient, was once healthy and active, ask family members to bring in photos showing the patient healthy at various ages or doing favorite activities. Displaying these photos in the patient’s room allows caregivers to appreciate the patient in wellness roles.

The concept of illness is one of imbalance or disharmony with the environment. The physical causes of illness are most easily recognized, such as exercise that induces an asthma attack or a fall that causes a broken bone. But illness can also result from a psychological, sociological, cultural, or spiritual imbalance. After the loss of a spouse, for example, one may experience loneliness, depression, and a loss of balance in the social and psychological aspects of life.

A hospitalization may increase disharmony if cultural beliefs and practices are not understood or upheld by health care providers (HCPs). A person faced with a terminal diagnosis may lose hope and direction in life, causing anxiety and despair. So rather than being exclusive concepts, health and illness are dynamic and ever-changing states of being. A health crisis such as a myocardial infarction (MI) overwhelms a patient’s ability to maintain a normal level of wellness. Two months after the MI, however, the patient could be enjoying a higher level of wellness than before the MI if he or she is following a healthy lifestyle.

THE NURSE’S ROLE IN SUPPORTING AND PROMOTING WELLNESS

The goal of nursing care is to help patients achieve their highest possible level of wellness. To do this, the patient’s strengths, assets, and resources, as well as weaknesses, liabilities, and disabilities, are considered. Working together, the patient, family, and members of the health care team develop a plan of care that includes wellness goals and a plan of action to accomplish those goals. The plan of care focuses on six main areas:

- Mobilizing resources
- Providing a safe and adaptable environment
- Helping the patient learn about his or her health problem and treatment
- Performing and teaching the patient to perform health care procedures
- Anticipating problems and recognizing potential crises
- Evaluating the plan and progress toward the goals with the patient and family

Nurses assume a variety of roles in promoting the health of their patients, such as educator, advocate, caregiver, and consultant.

DEVELOPMENTAL STAGES

Understanding the patient’s developmental stage can help the nurse more accurately assess health and health practices. The developmental stages of life focus on the balance a person must achieve for high-level wellness within that stage. Erik Erikson (1980, 1993) described eight stages of psychosocial development (Table 14.1). These stages illustrate the acquisition of a sense of trust in self and others and a sense of personal worth. Each stage must be completed before accomplishing the next. The first five stages describe the development of the child and adolescent. The last three stages relate to young adulthood, middle adulthood, and late adulthood and are discussed next.

The Young Adult

Erikson’s sixth developmental stage, from ages 18 to 40, addresses intimacy versus isolation. The young adult’s task is to develop relationships with a spouse, family, or friends that are warm, affectionate, and developed through fondness, understanding, caring, or love. When this stage is not successfully resolved, the person typically experiences isolation from others. Physically, growth is usually completed by age 20. Socially, young adults begin to move away from their parents to start their own families. The young adult begins to develop a place in society through school, work, and social activities. This is the stage in which intimacy or closeness develops with partners and friends. Decisions to have a pet, to marry, and to have children show the desire for intimacy. Challenges to intimacy are tasks that must be overcome in this stage. Melding one’s traditions and customs with the traditions and customs of a spouse, family, and friends is a major responsibility, as is the passing on of culture to children. Values and beliefs, which arise from a person’s culture or conscience, serve as guidelines for behavior for the young adult.

Common Health Concerns

The lifestyle choices of young adults may place their health at risk. Health promotion for this age group focuses on preventing...
or limiting risks through teaching. Young adults should understand the importance of diet and exercise in maintaining health for themselves and their children. Lifelong positive health practices help prevent long-term health complications. Avoiding sun exposure and using sunscreen are important to avoid sunburn, permanent sun damage to the skin, and increased risk of skin cancer. Tobacco use started in the teen years is often carried on throughout young adulthood and is linked to chronic bronchitis, emphysema, and oral, throat, and lung cancer in later life. Additional preventive measures that may be taught at this stage include breast self-examination (BSE) for women and testicular self-examination (TSE) for men.

In the early part of young adulthood, the individual is in the workforce or is preparing for the work world with a college or vocational education. Being a novice in the work world and accepting new independence, freedom, and responsibilities can introduce stressors into the young adult’s life. Overeating, alcohol use, drug use, cigarette smoking, and violence are risky lifestyle choices and poor coping mechanisms for stress. Young adults need to be aware of their individual stressors and be encouraged to develop positive coping mechanisms for stress. Exercise, support groups, music, and meditation are positive ways to cope with stress.

Although marriage commonly occurs during this phase, this group also has the highest rate of divorce. The blending of two people into a couple requires a lot of creative communication and loving care. When stressors overwhelm the couple’s coping mechanisms or coping strategy, the relationship may be at risk.

If young adults are sexually active with multiple partners, they are at risk for sexually transmitted infections. Safer sex guidelines and information on birth control should be available for the young adult.

Pregnancy is a common health occurrence for women in this age group. Because research indicates that a mother’s health practices directly affect the health of the developing fetus, nutrition, drug and alcohol use, physical health, and effective stress coping mechanisms are lifestyle issues that need to be discussed with every pregnant woman. Prenatal care should be encouraged and readily available to pregnant women.

The Middle-Aged Adult

In the middle adult years, ages 40 to 65, the psychological developmental stage is developing generativity versus self-absorption. Generativity includes a sense of productivity and creativity and is demonstrated by concern and support for others, along with a vision for future generations. Unresolved conflict may be seen as preoccupation with personal needs or self-absorption.

Physically, middle-aged adults start to notice signs of decreased endurance and intolerance for physical exercise if they have not maintained healthy lifestyle choices. Socially, their children are adolescents or young adults who need assistance with entering adulthood and launching their own careers and families. The term empty nest has been used to describe the middle-aged couple’s home after their children have left.

This period is often complicated by the challenging demands of also caring for aging parents. Today’s middle-aged adult generation has been labeled the sandwich generation because of the need to care for their children and their aging parents at the same time. Middle-aged adults look over their lives and assess accomplishments versus unrealized goals. Midlife crisis may occur as this self-inspection leads to a desire to change work, social, or family situations to try to meet unrealized goals. Planning for retirement by developing meaningful pastimes and interests outside of work and preparing for financial security is another important task during this stage.

### CRITICAL THINKING

Mrs. Michaels

- Mrs. Michaels, age 25, and her husband have been trying to start a family. Mrs. Michaels visits her physician, who confirms that she is pregnant. What information and health practices should Mrs. Michaels and her husband be taught during a prenatal health examination?

Suggested answers are at the end of the chapter.
Common Health Concerns

The need for immunizations continues into adulthood (visit www.CDC.gov). Unhealthy choices, such as smoking, use of alcohol or drugs, a sedentary lifestyle, a diet high in saturated fat, or overeating, often have serious consequences for middle adulthood. Hypertension and heart disease are major health concerns, as are chronic bronchitis, emphysema, and lung cancer. Cardiovascular disease and cancer cause most of the deaths in this age group. However, middle adulthood is not too late to begin lifestyle changes that positively affect health, such as regular exercise, not smoking, healthful eating, weight reduction, and using positive stress-coping mechanisms. Helping adults in this age group recognize the benefits of these positive lifestyle choices and empowering them to change is the major challenge for HCPs.

The Older Adult

The final developmental stage affects adults from age 65 until death. Ageism is a term that describes stereotypical misconceptions about older adults in society. Although they are the most diverse age group, common misconceptions about older people include that they are senile, disabled, and in nursing homes. However, more positive attitudes about aging are developing, in part as a result of the growing number of older adults. Advances in living conditions and health care have allowed more people to reach old age. People are living productive, fulfilling lives into their 80s, 90s, and even 100s. Older adults are likely to be found working in their gardens, hiking, exercising, or socializing (Fig. 14.1). Some older adults continue to work beyond typical retirement age or begin a rewarding second career after retiring.

Developmental work for older adults focuses on integrity versus despair. In this stage, older adults look back and evaluate what they have done with their lives. Integrity refers to accepting responsibility for one’s life so far and reflecting on it in a positive way. Reaching this stage is a sign of maturity. Failing to reach this stage is an indication of unsuccessful completion of previous stages, causing feelings of despair that life has been lived in vain, and a fear of death. Reminiscence therapy may be one way to assist the older adult through this stage.

Aging is associated with role changes and transitions. Some roles, such as employee, son, or daughter, are lost because of retirement, death, or illness, causing sadness or depression. New roles may arise, such as grandparent, volunteer, or widow/widower. With retirement, household management roles may need to change. If the older adult becomes ill and dependent and needs to be cared for by an adult child, the parent–child role may be reversed.

Health, relationships, lifestyle choices, and environment influence the diversity found in this age group. Physical health is often a concern for older adults. Chronic health problems that require medication and treatment often require lifestyle changes or adaptations.

Life events such as decreased physical ability, retirement, illness, or death of a spouse are challenges that older adults face. Reminiscence may be one way to assist the older adult through this stage.

CRITICAL THINKING

Mr. Paul

Mr. Paul, age 54, calls his HCP’s office for the fourth time this month reporting severe indigestion and requesting a medication to fix it. He has refused to have an x-ray examination or other diagnostic tests because he “can’t fit them” into his “busy schedule.” Mr. Paul has his own insurance business. His wife quit her job to supervise their 15-year-old son, who was not going to school every day. The couple’s twin daughters are both in college out of state.

1. What might be causing Mr. Paul to experience health problems?
2. What is affecting the developmental tasks Mr. Paul needs to perform?

Suggested answers are at the end of the chapter.

Reminiscence: re—backward + minisc—mind + ens—action
face. The older adult’s ability to cope with these stressors is essential for maintaining a sense of control. Coping with aging is influenced by the individual’s cultural beliefs. Cultural viewpoints on the social role and value of older community members affect the health of older adults. Sometimes the greatest loss for older adults is their lack of connection with the world and lack of being part of a greater purpose. However, being alone is not the same as being lonely. For some older adults, being by oneself for a time allows for reflection to better understand one’s situation. Older adults who feel unwanted or unloved are more likely to develop anxiety, depression, and failure to thrive.

**Common Health Concerns**

The focus of care for the older adult is assistance in meeting physical, psychological, cultural, sociological, and spiritual needs. Promoting self-care and encouraging the use of community services for seniors is important. Most older adults continue to live in their own homes or apartments, but impairment in mobility and the ability to carry out instrumental activities of daily living (IADLs), such as shopping for groceries, preparing meals, and cleaning and maintaining a home, threaten their independence. Having to ask or pay others to perform tasks that they formerly were able to do themselves is seen as a significant loss by many older adults. Adding the loss of a spouse, the death of friends, or the lack of social contacts further isolates an older person and can lead to depression and a feeling of hopelessness. The accumulation of losses can overwhelm an older adult’s resources and coping mechanisms and is related to a high rate of suicide, especially for older men. Suicide is the ultimate expression of hopelessness.

Older adults might need to be encouraged to remain active and to continue to pursue interests. Most communities have transportation services that operate to meet the needs of older adults. Senior centers offer diverse programs and services such as trips, dances and bowling leagues. Older adults can also continue to work as volunteers for schools, hospitals, nursing facilities, parks, museums, zoos, community theaters, and youth groups. Colleges and universities may offer discounted tuition for senior citizens, and there are Elderhostel programs across the country. Elderhostel offers thousands of educational travel programs, such as photography, Civil War history, nature survival, bird watching, and painting.

Chronic diseases can limit an older person’s ability to be independent in ADLs and IADLs. Hypertension is common in this age group, as are heart disease and strokes. Managing these conditions and living a healthy lifestyle can help keep the older adult active.

One of the most difficult tasks for the nurse in dealing with the older adult is to distinguish normal age-related changes from pathological changes. Changes in mobility and chronic pain may limit an older person’s activity and impede an active lifestyle. Pain is not normal and should be investigated rather than attributing it to aging and ignoring it.

**Falls**

Falls are a serious concern for older adults, resulting in decreased independence and death. Osteoporosis is a bone disease common among postmenopausal women and men over age 80, causing bone weakness and fracture risk. Falls and accidents can be prevented by in-home safety assessments and altering the home environment to ensure the safety of the older adult. Bathrooms should be equipped with grab bars and nonskid mats. Bath chairs or benches make getting into a bath or shower safer. Removing clutter, throw rugs, small furniture, and electrical cords decreases the risk of falls.

Hearing and vision loss can affect physical and psychological health in the older adult. Good sensory function is needed to protect oneself from accidents, social isolation, and limitations in self-care. One of the most dramatic losses for many older adults is not being able to safely drive a car. This can be associated with a loss of independence. Sensory impairments can further isolate the patient. Impaired vision can be caused by decreased peripheral vision, macular degeneration, cataracts, or glaucoma. Many older adults continue to drive during the day but not at night because of night vision problems. Decreased hearing is also common in older adults. Loss of high-pitch discrimination and reduced ability to filter background noise causes older adults to hear the background noise more clearly than a one-to-one conversation when in a crowded room. Social stigmas related to memory changes such as forgetfulness and dementia are a serious worry for many older adults. They commonly confuse depression with memory changes and attempt to hide their symptoms rather than seek treatment.

**CHRONIC ILLNESS**

A major challenge facing HCPs is the management and prevention of chronic illness. A chronic illness is defined as an illness that is long lasting or that recurs. It usually interferes with the person’s ability to perform ADLs. A chronic illness is never completely cured or prevented. The amount of disability a person has depends not only on the condition and its severity but also on the individual effects for that person. The degree of disability and altered lifestyle relate as much to the
person’s perception of the disease as to the disease itself. For example, both John F. Kennedy and Franklin D. Roosevelt would have been eligible for 100% disability benefits because of their chronic illnesses, but both managed to serve as presidents. The long-term effects of treatments such as radiation therapy can become chronic diseases in themselves. Radiation for a tumor can leave the person with persistent diarrhea that may cause malnourishment and exhaustion.

CRITICAL THINKING

Mrs. Ricardi

Mrs. Ricardi, age 87, lives alone in her small apartment. Her daughter and son are both retired and live in the same community. Mrs. Ricardi had a dizzy spell, so her daughter brought her to the hospital emergency department (ED). Upon admission, Mrs. Ricardi’s blood pressure was 208/128 and she had blurred vision in the left eye that resolved after 1 hour in the ED. She was diagnosed with hypertension, which possibly contributed to a small stroke or transient ischemic attack (TIA). Mrs. Ricardi was started on metoprolol (Lopressor) 100 mg daily. She was discharged to her home with instructions to limit salt in her diet and to begin an exercise program. The plan of care addressed safety issues.

1. Why might Mrs. Ricardi be at increased risk of falling?
2. What patient-centered nursing interventions would help promote Mrs. Ricardi’s independence and safety?
3. The nurse is to give metoprolol 100 mg, and 50-milligram tablets are available. How many tablets should the nurse give?

Suggested answers are at the end of the chapter.

Types of Chronic Illnesses

Chronic illnesses have different causes (Box 14-1). These illnesses have varying degrees of severity and effect on length of life. One chronic illness can lead to development of other illnesses, such as hypertension, which then causes chronic renal failure. Chronic illnesses can begin at various ages, but with advancing age, the likelihood of developing chronic illness increases, and many older adults have several chronic illnesses at once (Box 14-2).

Gerontological Influence

As people live longer, spouses or older family members are increasingly being called on to care for a chronically ill family member. Children of older adults who themselves are reaching their 60s are being expected to care for their parents. These older caregivers may have chronic illnesses of their own. A family in this situation is at great risk for ineffective coping or further development of health problems.

Incidence of Chronic Illness

The incidence of chronic illness is rising for several reasons. First, people are living longer, in part because of better hygiene, nutrition, exercise, vaccinations, antibiotic development, and new treatment options. Fewer people are dying from acute diseases. As a result, a larger older population is living long enough to develop many chronic illnesses. Second, medical advances have resulted in reduced mortality from some chronic illnesses, so that patients live longer with these illnesses. Third, today’s technology and modern lifestyles may contribute to the development of some chronic illnesses. Examples include a sedentary lifestyle; exposure to air and water pollution, chemicals, and carcinogens; substance abuse; and stress.

Box 14-1 Examples of Chronic Illnesses by Cause

**Genetic**
- Cystic fibrosis
- Huntington’s disease
- Muscular dystrophy
- Sickle cell anemia

**Congenital**
- Heart defects
- Malabsorption syndromes
- Spina bifida

**Acquired**
- AIDS
- Arthritis
- Cancer
- Chronic obstructive pulmonary disease
- Diabetes
- Head or spinal cord injury
- Multiple sclerosis
problems. Assessment of all members of the family with older adults is essential to ensure that their health and coping needs are being met. Healthy People 2020, a national health promotion and disease prevention initiative, calls for public health surveillance and health promotion programs for people with disabilities and their caregivers (www.healthypeople.gov).

Older adults are concerned about becoming dependent on others. They may become depressed and give up hope if they feel that they are a burden to others. Establishing short-term goals or self-care activities that allow them to participate or have small successes are important nursing actions that can increase their self-esteem (see “Cultural Considerations—Traditional Appalachians”).

Barriers to care for a chronically ill older patient include a lack of information about treatments, medications, or special diets and being unfamiliar with supportive services in the community such as meal programs or respite care. Developing an understanding of this information and share it, as well as a resource number for older patients and their caregivers (www.healthypeople.gov).

Effects of Chronic Illness

When a patient lives with a chronic illness, many adjustments are usually needed. Lifelong routines and habits may need to be changed to cope with the illness. Treatment needs, such as going to therapy sessions, performing peritoneal dialysis exchanges, or monitoring blood glucose, can interrupt daily life and require adaptation into the daily routine.

**Chronic Sorrow**

Chronic sorrow is a normal response felt by those affected by a chronic illness. It is an intermittently occurring sadness in response to losses caused by a chronic illness. It can be felt by the patient or the patient’s significant others. The nursing diagnosis **Chronic Sorrow** may apply to those with chronic illness. When this sadness occurs, nursing care should focus on active listening to understand the loss and then on offering appropriate comfort and support. Providing information and assisting with coping strategies such as fostering support systems are great interventions to help those with chronic sorrow.

**Spiritual Distress**

Patients with chronic illness can experience spiritual distress when faced with the limitations of their illness. Maintaining patients’ quality of life includes assisting with their spiritual needs. Religious and spiritual needs are important to most people whose lives have been disrupted by new challenges from chronic illness. Patients must be helped to find realistic hope and meaning in the illness. Interventions that address spirituality might need to be performed first to promote later success with the plan of care.

Several factors may make one uncomfortable in caring for a patient’s spiritual needs. These factors include a lack of training, a lack of understanding of one’s own spiritual needs and beliefs, and not recognizing or believing that this is your role. Develop a comfortable approach in assessing and meeting patients’ spiritual needs. Examine your own spiritual needs to define a personal spiritual view. By doing this, you will develop insight into others’ spiritual needs and resources, as well as gain a greater understanding of issues surrounding your patients’ spiritual needs.

Many people use spirituality to cope with chronic illness. It helps them give a sense of wholeness, hope, and peace during a time filled with uncertainty and anxiety. Spirituality plays an important role in empowering patients to handle their condition. It is a source of inner strength that allows the patient to experience a sense of unity. Hospital interventions may include use of a meditation room for quiet reflection or prayer, chaplain visits, or worship services. To help meet the patient’s spiritual needs, assist the patient with transportation to the meditation room or worship services.

### Box 14-2 Examples of Chronic Illnesses in the Older Adult

- Arthritis
- Cerebrovascular accident
- Chronic lung disease
- Dementia
- Diabetes mellitus
- Heart failure
- Hypertension
- Orthopedic dysfunction
- Peripheral vascular disease
- Sensory losses: vision, hearing

Cultural Considerations

**Traditional Appalachians**

Traditional Appalachians believe that disability is natural and inevitable with aging. This belief discourages the use of rehabilitation as an option. Thus, to promote rehabilitation efforts among Appalachians, the nurse may need to stress self-help and a return to physical function.
Accreditation agencies require the spiritual needs of patients to be addressed and documented by nurses. Nursing diagnoses related to spiritual needs may include Spiritual Distress, Readiness for Enhanced Spiritual Well-Being, and Impaired Religiosity.

**Powerlessness**

A chronic illness can take an unknown course in relation to its seriousness and controllability. This leaves the patient vulnerable to the many phases of a chronic illness: the diagnosis, the instability phase, an acute illness or crisis, remissions, and a terminal phase. Treatment that the patient undergoes may be painful, frightening, and invasive. A patient who does not understand what is happening can feel overwhelmed and alone. This contributes to a feeling of powerlessness because the patient cannot control the outcome (Fig. 14.2). This lack of control throughout an illness influences the patient’s reactions to the illness. The nursing diagnosis Powerlessness can apply to chronically ill patients.

**COPING.** Patients can be helped to feel more in control of their illness if you remember to include them in their care; listen to their feelings, values, and goals; and explain all procedures before they occur. Avoid using complex medical language when talking with patients to increase their understanding and feeling of being included in their care instead of isolated. In addition, coping with a chronic illness can be aided if the patient develops a positive attitude toward the illness. This can be accomplished if the patient gains knowledge, uses a problem-solving approach, and becomes motivated to continue adapting to the illness.

Having a variety of coping techniques can be useful. Ask the patient’s perception of the illness and coping techniques that the patient has previously used successfully. New coping resources may need to be added to help the patient effectively deal with the chronic illness. Support services in the community should be offered to the patient and family. To cope effectively, the patient should be helped to become comfortable with the newly defined person he or she is to become. The nursing diagnoses Ineffective Coping, Compromised Family Coping, Disabled Family Coping, and Readiness for Enhanced Family Coping may apply to those dealing with chronic illness.

**HOPE.** Before coping resources can be used, hope must be established in the patient. False hope is not beneficial and should be replaced with realistic hope. Providing patients with accurate knowledge regarding their fears helps do this. Hope should not be directed toward a cure that may not be possible but rather at living a quality life with the functional capacity that the patient has. Over the course of the illness, hope needs to be maintained for both the patient and family. Periodically assess if the patient is maintaining hope. Many studies have shown that patients adapt better when hope is high (see “Evidence-Based Practice”). The nursing diagnoses Readiness for Enhanced Hope or Hopelessness may apply to chronically ill patients.

Many nursing interventions may increase hope. The use of humor helps patients be lighthearted and hopeful. Patients should be tactfully and sensitively encouraged to live each moment to the fullest and experience the joy of being alive. Awakening the senses to appreciate the environment can bring a feeling of hope and peace. Simple things, such as the smell of baking bread, the clean scent of the air after a rain, or the scent of pine trees, can make one appreciate the beauty of nature and inspire hope. Family members need to be encouraged to help foster hope for the patient. In doing this, family members may feel hopeful as well. During times of
Sexuality

Chronic illness can affect a patient’s sexuality, which includes femininity and masculinity as well as sexual activity. Body image changes affect the way patients view themselves and are viewed by others. If patients have a negative body image perception, they may withdraw and become depressed. When interacting with patients, be aware of your facial expressions, nonverbal cues such as appearing hurried or keeping a distance, use of or lack of touch, and amount of time spent with the patient. When patients believe they have lost their femininity or masculinity, their self-worth decreases. Interventions to enhance sexuality should be used, such as obtaining a wig for patients undergoing chemotherapy.

There are many forms of sexual expression. Sexual intimacy can include touching, hugging, or sharing time together. Provide patients with the opportunity to discuss sexuality concerns or questions. Assume a professional and confidential approach to this topic, which is usually considered a private matter by patients. Chronically ill patients can be referred to sexuality counselors for information on ways to cope with sexual issues in relation to their illness.

CRITICAL THINKING

Mr. Soloman

- Mr. Soloman, age 88, lives in his own home with his wife of 60 years. He is in good health except for limited vision. He grows prize-winning tomatoes each year, plays golf weekly, and walks every day to the neighborhood stores. The employees know him and cheerfully assist him.

- Mr. Soloman’s wife was the homemaker, and now she is in the early stages of Alzheimer’s disease. She cannot perform ADLs, so he has willingly assumed the caregiver role. They complement each other’s limitations because she has good vision and is helpful when she is not confused.

- Over time, Mr. Soloman’s wife’s health declines, and she enters a long-term care facility. Mr. Soloman remains in his home alone, which concerns his family. They eventually convince him to move into senior housing. He is very reluctant to leave his home and does not actively participate in moving and selling his home. Mr. Soloman rarely leaves his apartment, sleeps 14 hours a day, and eats one daily meal. He tries to visit his wife by taking a bus but finds it difficult because of his limited vision, so he rarely sees her. A few months later, Mr. Soloman develops pneumonia and dies in his sleep.

1. Why do you think Mr. Soloman behaved the way he did after he moved?
2. What patient-centered interventions could have been used to empower Mr. Soloman?
3. Why might Mr. Soloman have developed pneumonia and died?

Suggested answers at end of chapter.
adapt to them as well. Family members may have to take on new roles themselves to compensate for roles the patient can no longer perform. The nursing diagnosis of Ineffective Role Performance should be included in the plan of care for the patient and family.

The patient is faced with giving up aspects of old roles at the same time that new roles related to being chronically ill need to be assumed. Grieving accompanies the loss of old roles. If a patient is no longer able to participate in social events such as golfing or being a committee member, grief work needs to occur to help the patient accept the loss and maintain dignity. With other roles, only certain aspects of the role may change. For example, in the parenting role, patients may still function as support systems for a child, although they can no longer be the disciplinarian. Whatever the role loss, the patient needs to be allowed to grieve the loss. The nursing diagnosis of Grieving may help in planning care for the patient.

New roles the patient may have to assume related to chronic illness include dependent, ongoing health care consumer self-care agent, and chronically ill person. Patients need to learn how to cope with these new roles. They need to gather knowledge and be given understanding while they become familiar with these roles. For patients used to being independent before the illness, being dependent on others to meet ADLs can cause a loss in self-esteem. Navigating the complex health care and financial reimbursement systems can be overwhelming. Transportation needs and waiting times for medical appointments can be difficult for the patient who must deal with them on an ongoing basis. Becoming a self-care agent requires assuming responsibility for meeting one’s own care needs. Deficient Knowledge and Readiness for Enhanced Knowledge are nursing diagnoses helpful for fostering learning for these new roles.

As patients live with chronic illness over time, they become experts on their own illness. However, today’s health care system often tends to assume control over patients and does not respect the patient’s own knowledge. Patients who are not given this respect may take charge of caring for themselves by seeking knowledge and trying complementary healing methods. Being sensitive to the patient’s knowledge and respecting it increases patients’ self-esteem.

**Family and Caregivers**

Families are affected by the chronic illness of a family member in many ways. Most chronic illness care is provided in the home so that families become involved in the management of the illness (see “Home Health Hints”). Family members may have to take on new family roles or assume the role of caregiver. Decreased socialization, lost income, and increased medical expenses can increase family stress and tension.

Families must learn to cope with the stress of illness and its often unpredictable course. Most families develop ways to cope with the patient’s illness the majority of the time and may become closer as a family unit. Families often deal with the illness on a day-by-day basis and take a passive approach to letting problems work themselves out. During times of exacerbation or crisis, however, the family may need coping assistance (Box 14-3).

**Box 14-3 Caregiver Resources**

- aarp.org/caring
- alzheimers.gov
- caregiver.org
- eldercare.gov

Patients are often concerned about being a burden to their families. It is important to determine both the family’s and the patient’s feelings about the care required by the patient. The family’s ability to provide this care adequately must also be considered in care planning. If the family lacks the desire, skills, or resources to adequately care for the patient, alternative care options must be explored such as home health care, adult foster care, or long-term care.

Caregivers often have certain ideas about the care that the patient should receive. This may come into conflict with the views of HCPs. Caregiver input into the patient’s plan of care should be sought so that everyone has a clear understanding of goals and expectations for the patient’s care.
Caregivers commonly experience depression, role strain, guilt, powerlessness, and grieving related to care giving. Being aware of this will help nurses detect indications that caregivers are in need of help in dealing with these feelings. Chronic-care coaches are available who can provide care-givers with insight, encouragement, and support for caring for someone who is chronically ill. Nursing diagnoses for caregivers include Risk for Caregiver Role Strain and Caregiver Role Strain.

**RESpite CARE.** When caregivers are required to pro vide 24-hour care for a patient, they can experience burnout, fatigue, and stress, which, if extreme, might lead to patient abuse. Caregivers may not be able to leave patients alone even briefly because of wandering behaviors, confusion, or safety issues. They may not ever be able to get a normal night’s sleep and suffer from sleep deprivation because of the patient’s wandering or around-the-clock treatment needs.

Caregivers must be given periodic relief from their responsibilities of caregiving to reduce the stress of always having to be responsible. Everyone requires private time for reflection or pursuing favorite hobbies or interests. Caregivers may need to get away overnight or for a weekend simply to sleep soundly and be refreshed.

**Resources**

- Encourage the family of bed-confined patients to purchase an inexpensive portable intercom (such as a nursery monitor) to give the caregiver freedom to move about the house and hear the patient if help is needed.
- When patients have the use of only one hand or arm, provide a sponge for personal grooming instead of a washcloth; it is easier to use and hold.
- The home health social worker should be informed of any patient concerns regarding cost of medicines or equipment. Many programs are available to assist chronically ill people to obtain resources.

**Cardiopulmonary Resuscitation**

- Always carry a pocket mask for cardiopulmonary resuscitation (CPR).
- Encourage discussion regarding advance directives with the patient and family/caregiver early in the care process. Decisions regarding resuscitation and the use of technology to prolong life are more difficult when the patient is in crisis.
- Refer families to community CPR classes as desired. Families can be empowered and the patient may feel more secure when families are taught CPR.
- Patients and families should be taught that if an ambulance is called, they should turn on an outside light, open the door, and move furniture, if possible, to enable the emergency medical technicians to get to the patient more easily.

**Respite care** is designed to provide caregivers with a much-needed break from caregiving by providing someone else to assume the caregiver role. Be familiar with your community’s respite care services and share that information with caregivers. Most respite care is provided by volunteers who receive training.

**CRITICAL THINKING**

**Mrs. Burden**

- Mrs. Burden, age 64, is caring for her husband, who has Alzheimer’s disease. He wanders. He gets up at night and in freezing winter weather is found walking down the street in only his pajamas. He tries to cook and burns the pans. He cannot express his needs. He disrobes frequently and is incontinent. Mrs. Burden quit her job to care for him. She no longer goes to lunch weekly with her friends. Her children live out of town. She places a chair and tin cans in front of the home’s doors as an alarm in case her husband opens the doors while she tries to sleep.

1. What indicates that Mrs. Burden is experiencing stress related to caregiving?
2. What nursing diagnoses should be included in a plan of care for Mrs. Burden?
3. What nursing interventions would be beneficial for Mrs. Burden?

*Suggested answers are at the end of the chapter.*

**Finances**

Managing a chronic illness can be expensive. Income can be lost if the patient is unable to work or caregivers are forced to stay home. Insurance may not cover all of the patient’s expenses. Family savings can quickly be used up and place a strain on families. This can lead to the nursing diagnoses Compromised Family Coping, Disabled Family Coping, or Readiness for Enhanced Family Coping. Nurses may need to refer patients for financial aid.

**Health Promotion**

Health promotion is possible and necessary at all levels of age or disability. With the increase in the older population, it is essential to understand the role of health promotion for older adults who have chronic illness. Patients with chronic illness make daily lifestyle choices that affect their health. For example, the patient with chronic lung disease who smokes can make a choice to smoke or to quit smoking. Patients with degenerative joint disease can choose whether to keep their weight within ideal weight ranges to reduce wear and tear on their joints. Those with arthritis can reduce their BMI levels by pacing their activities and scheduling daily rest periods.

Those with chronic illness often consider health promotion important, so encourage health promotion efforts. Patients...
need to be helped to strive toward high-level wellness. This can be achieved by looking at the patient’s strengths and weaknesses holistically to develop a plan of care. Determine the patient’s risk factors to help plan methods of promoting health. Providing patients with knowledge to make informed decisions empowers them to take control of their lives and reach their greatest potential.

**Nursing Care**

Because of the nature of chronic illness, nurses should understand the unique needs of patients and families experiencing chronic illness. These needs differ from those of patients experiencing acute care as far as depth of knowledge and the compounding problems that the patient usually faces. Develop an understanding that the wishes of the patient must be respected even if you do not agree with them. Patients have the right to establish their own goals in partnership with the healthcare team. Patients are participating in or leading their own daily bedside rounds with the healthcare team in institutions. This is true patient-centered care!

Most chronic illness care occurs in the home and community rather than the acute care setting. Therefore, family members and caregivers, even more so than in acute care, must be assessed and included in the plan of care. As the numbers of those with chronic illness grow, community support for chronically ill people and their caregivers needs to continue to grow. Training programs for caregivers should be available and offered affordably.

A major focus of nursing care for the chronically ill is teaching. These patients and their families have tremendous educational needs if they are to learn to cope successfully with a long-term illness. The following are primary tasks that chronically ill patients need to perform:

- Be willing and able to carry out the medical regimen.
- Reorder time to meet demands caused by the illness, such as treatments, medication schedules, and pacing of activities.
- Understand and control symptoms.
- Prevent and manage crises.
- Adjust to changes in the disease over the course of time, whether positive or negative.
- Prevent social isolation as a result of physical limitations or an altered body image.
- Compensate for symptoms and limitations in order to be treated as normally as possible by others.

Explain individualized interventions to deal with these tasks during teaching sessions. Provide dignity and show respect to all patients (“Patient-Centered Care—Mr. Lyman”). Unique approaches are needed to positively assist chronically ill patients and their families on their long-term journey.

**Patient-Centered Care**

**Mr. Lyman**

To the nurse caring for me:

- Don’t call me “sweetie” or “honey.” My name is Mr. Lyman. If I want you to call me by my first name, I’ll tell you.
- Be polite!
- Don’t give me a huge glass of water—give me a small glass and don’t fill it full. Otherwise, when I drink it, it spills all down the front of me.
- When you leave my meal tray, make sure I can reach it. Then when you take it away, don’t leave a bunch of stuff on my table. There is not much room on those little tables.
- Ask how I like my blankets. Don’t just do them the way you do for anyone else.
- Make sure my call light is where I can reach it.
- Make sure my overhead light is working and that I can reach it.
- Keep a wastebasket where I can reach it.
- Ask if I need anything before you leave the room.
- Try to talk quietly in the hallway, instead of being so loud.
- Thank you for preserving my dignity and showing me respect. I appreciate it!

**SUGGESTED ANSWERS TO CRITICAL THINKING**

**Mrs. Michael**

Prenatal education information should be offered to Mrs. Michael and her husband. This education should include an overview of Mrs. Michael’s health needs, what to expect during pregnancy, ways Mrs. Michael’s husband can be supportive, and information on prenatal classes. Mrs. Michael’s physical examination should include a vaginal examination, blood pressure, and blood work. It is important to be aware of any sexually transmitted infections that may be transferred to the developing fetus or during birth. A rubella titer (a test for immunity to rubella or measles) is important because of potential birth defects if the mother has rubella while pregnant. Elevated blood glucose may be a sign of diabetes, and low red blood cell counts and low hemoglobin are related to anemia.

To prepare a woman for pregnancy, prenatal vitamins or vitamins with iron and folic acid (necessary for
effective neural tube development in the first 3 months of pregnancy) are recommended. Because of the increased workload of the heart during pregnancy, blood pressure needs to be closely monitored. Eating a balanced diet, maintaining an exercise program, and continuing to develop effective and positive ways to deal with stress are very important for pregnant women. In preparation for pregnancy, Mrs. Michael also needs information on the negative effects that cigarette smoking, alcohol use, and drug use can have on the developing fetus.

**Mr. Paul**
1. Mr. Paul’s physical health is being affected by poor diet choices, excessive stomach acid secretion or other gastrointestinal problems, and stress.
2. It is easy to recognize the psychological stress related to parenting skills when a child is in trouble. Decreased family income with increased family expenses (two children in college) can cause financial strains and more economic pressure on Mr. Paul’s business. With family problems or health problems, Mr. Paul may be questioning why things are happening to him and his family, causing him spiritual distress.

**Mr. Klein**
1. Ageism, stereotypical misconceptions about older adults, is occurring. This can lead to the belief that pain is part of the aging process and, therefore, it is often not diagnosed and treated appropriately.
2. Gathering data to assist with the diagnosis of the cause of the pain and treatment for the pain would improve Mr. Klein’s quality of life. Taking him seriously would also convey that Mr. Klein is a valued member of society and increase his self-esteem.

**Mrs. Riccardi**
1. Falls could be caused by environmental problems, such as throw rugs that may move or cause tripping, clutter, electrical cords in walking paths, lack of hand grips in the bathroom, or lack of nonskid mats in the shower or tub. Poor vision and altered depth perception can result in missing a stair step or obstacles. Weakness or orthostatic hypotension can cause an unsteady gait or fall.
2. It is important for the nurse to instruct the patient and family about home safety. Mrs. Riccardi may even benefit by using a cane or a walker if she is unsteady. Because Mrs. Riccardi lives alone, an emergency alert system, such as a small transmitter that is worn around the neck or wrist with a button that can be activated in emergencies, would be beneficial. When activated, the transmitter alerts an answering service to contact designated individuals to check on the patient. Safety with medications is also an important consideration. Patients who take medications that lower blood pressure must be aware of the potential for orthostatic hypotension. Orthostatic hypotension is a drop in blood pressure that happens when a person moves from a lying to sitting or sitting to standing position. It is often accompanied by dizziness or light-headedness. Some people may even faint, causing a fall.
3. Two tablets of 50 mg each.

**Mr. Soloman**
1. Mr. Soloman had lost control of his world and felt powerless. His environment, both home and outdoors, was shrinking. He had to give up his daily routines and interactions with others. His purpose in life was gone when he was no longer caring for his wife. He was separated from his loved one. His visual limitations made his new environment unfamiliar and frightening.
2. Options to keep him safely in his home could have been explored with his input. After the move, he should have been thoroughly oriented to his environment. He should have been asked to explain what he wanted his life to be like as he adapted to this new period. Hobbies and interests should have been continued. Visual support services should have been contacted for ideas. Transportation should have been arranged to allow him to visit his wife and golf. It should have been determined whether phone calls to his wife were possible.
3. He was depressed and slept from a lack of interests. His lungs were at risk for pneumonia because of his long periods of immobility. He lost hope and gave up on living, which decreased his ability to fight the pneumonia.

**Mrs. Burden**
1. Mrs. Burden is at risk for sleep deprivation, fatigue, stress, and burnout.
2. Nursing diagnoses include *Disturbed Sleep Pattern, Fatigue, Social Isolation, Risk for Caregiver Role Strain,* and *Deficient Knowledge.*
3. Beneficial nursing interventions would include teaching about Alzheimer’s, a chronic-care coach, respite care referral, alarm devices for wandering, and stress management techniques.
Chapter 14  Developmental Considerations in the Nursing Care of Adults  275

REVIEW QUESTIONS

1. The nurse is collecting data regarding a 68-year-old patient’s developmental stage and finds that the patient is retired and that the patient’s spouse died 4 months ago. The nurse identifies the patient as being in which of the following developmental stages?
   1. Generativity versus self-absorption
   2. Identity versus role confusion
   3. Integrity versus despair
   4. Intimacy versus isolation

2. The nurse is planning care for a patient with heart disease. Which of the following effects should the nurse consider is most likely to occur with a chronic illness when gathering further data collection?
   1. Hopefulness
   2. Increased socialization
   3. Powerfulness
   4. Spiritual distress

3. A 70-year-old man is the primary caregiver for his wife, who has moderately severe Alzheimer’s disease. He becomes angry with her for spilling her dinner on the floor. He later feels guilty and begins to cry. The home health nurse is developing a plan of care. Which of the following would be an appropriate nursing diagnosis for the nurse to include?
   1. Caregiver Role Strain
   2. Hopelessness
   3. Powerlessness
   4. Risk for Caregiver Role Strain

4. A 64-year-old woman goes to a clinic for a yearly physical. She has a history of hypertension and osteoarthritis. In contributing to the plan of care, which of the following would be a priority intervention to promote wellness in this patient who has chronic illnesses?
   1. Demonstrating how to take a blood pressure
   2. Explaining hypertension and osteoarthritis
   3. Encouraging increased socialization
   4. Evaluating progress with the patient and family

5. The nurse is providing care for a chronically ill patient. Which of the following are appropriate nursing interventions for a chronically ill patient? Select all that apply.
   1. Limiting educational information
   2. Encouraging visits by family members
   3. Including family members in teaching sessions
   4. Setting the goals for the patient
   5. Limiting visits from friends
   6. Obtaining patient input on plan of care

6. Which of the following nursing interventions would be most appropriate for a patient with a chronic illness who is experiencing chronic sorrow? Select all that apply.
   1. Provide quiet time.
   2. Make time to listen.
   4. Limit interactions.
   5. Use active listening.
   6. Encourage hope.

7. The nurse would evaluate the patient with a chronic illness as responding positively to interventions for chronic sorrow if the patient stated which of the following?
   1. “I have nothing left to accomplish.”
   2. “Maybe tomorrow will be a better day.”
   3. “I should not keep hoping for a cure.”
   4. “There is nothing I can do.”

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Define aging.
2. List basic physiological changes associated with advancing age.
3. Describe the psychological and cognitive changes associated with advancing age.
4. Plan nursing care for the physiological and psychological changes associated with advancing age.
5. Identify nursing practices that promote safety for the older patient.
WHAT IS AGING?

Over time, it is easy to see changes that occur in the human body. Both physical structures and body functions undergo changes and declines with advancing age. Although there is not one commonly accepted definition or theory to explain these declines, there is an understanding that aging is a universal and normal process that starts at conception and continues until death.

Older adults are continuing to increase in number. According to the 2010 U.S. Census, 40.3 million adults were older than age 65. This represents a 15.1% increase for this age group from 2000 (U.S. Census Bureau, 2010). The fastest growing segment within this group was those aged 85 to 94.

For current population data and older adult information, visit www.census.gov or www.agingstats.gov.

In this chapter, aging is defined as a maturational process that creates the need for individual adaptation because of physical and psychological declines that occur throughout life. Even though aging truly begins at conception, the focus in this chapter is on the maturational process that is experienced after age 65 (older adult). People older than age 84 usually are the frailest, although chronological age should not be the basis for determining health issues. For some people, aging effects go unnoticed in their daily functioning; for others these effects cause varying degrees of impairment. Functional age (health, independence, and functional abilities) should be used as the basis of individual care needs. It is important to understand that most older adults function independently in the home and community. Many older people remain in the workforce by choice or financial necessity. With supportive, educative care as needed, these people are able to maintain their independent abilities. This chapter discusses aging changes and the resulting disabilities that can require more intensive nursing care than that required by older adults who are independent and healthy.

About 1.3 million (3.1%) of those aged 65 or older resided in skilled-nursing agencies in 2010 (U.S. Census Bureau, 2010).

NURSING CARE TIP

Placing older adults into one category titled "old" overlooks aging as a unique experience. The concept of functional age recognizes that aging is individual and promotes individualized nursing assessment and development of plans of care for the older adult.

Although aging is universal, it remains a unique experience for each individual. Factors that contribute to this process can be grouped into two categories. Intrinsic factors focus on genetic theories of aging, such as the biological clock theory or programmed aging theory, and on some aspects of physiological theories of aging, such as wear-and-tear theory or stress adaptation theory. Extrinsic factors focus on environmental influences, such as pollutants, free-radical theory, and stress-adaptation theory.

Regardless of which factors have the greatest influence on the process of aging, perception and attitude also play key roles in how changes over time affect the individual. It is through the filter of perception and attitude that the individual identifies, defines, and adapts to the changes that occur in structure and function over time. These factors have implications not only for older patients but also for their families and the health care providers (HCPs) working with them.

PHYSIOLOGICAL CHANGES

Over time, cells change and do not function as efficiently as in earlier years (Table 15.1). Compared with cellular changes, the physical changes seen when looking at an older person are slight. Cellular decline in structure and function increases in severity and extent over time. Although the body works hard to maintain homeostasis, it is often unable to fully adapt to many of the declines that result from aging. Cells that die cannot regenerate themselves. As a result, structures are altered, and the body tries to adapt to make the revised structure meet functional demands.

Common Physical Changes in Older Patients and Their Implications for Nursing

Key Changes in the Muscular System

Age-related changes in the muscular system include the following:

- Decrease in muscle mass, so muscles look smaller
- Decrease in muscle tone, so muscles look less toned
- Slower muscle responses, so response time is increased
- Decrease in elasticity of tendons and ligaments, restricting movements

NURSING CARE. Changes in the muscular system have implications for movement, strength, and endurance. Restricted movements are most commonly seen in the arms, legs, and neck of the older patient, who can have limited range of motion (ROM) in these areas. Because muscle response abilities are slowed, it will take longer for the older patient to move. This increased response time has implications for the older person’s confidence in being able to perform routine tasks.

Key Changes in the Skeletal System

Age-related changes in the skeletal system include the following:

- Eroding cartilage
- Exaggerated bony prominences
- Joint stiffening and decreased flexibility

- WORD • BUILDING • homeostasis: homios—similar + stasis—standing

**Osteoporosis**, a thinning (decrease in density) and softening of the bone

* Shortening in height caused by water loss in the intervertebral disks of the spinal column and flexion of the spine associated with the influence of gravity over time.

**NURSING CARE.** Because muscles and bones work together for movement, aging skeletal changes are most obvious when the older patient is moving. **Contractures** of the fingers and hands can limit the person’s ability to perform self-care tasks called **activities of daily living** (ADLs). It is important to assist the patient with ROM exercises if help is needed to prevent the long-term disabilities that contractures bring (Fig. 15.1). Performing ROM exercises in warm water helps the patient for whom movement is uncomfortable. If the person has arthritis, the administration of any prescribed anti-inflammatory medications should be timed so their action peaks when the exercises begin. Older patients on anti-inflammatory medicines should be monitored closely for gastrointestinal (GI) upset or bleeding and taught the symptoms of bleeding to report.

Decreased bone density is influenced by diet and weight-bearing exercise, so balanced diets rich in calcium and vitamin D and safe and sensible weight-bearing exercise programs should be promoted (see “Evidence-Based Practice”). Encourage patients to ambulate whenever possible wearing supportive, sensible shoes with nonskid soles. In addition to making sure the environment is safe for walking, sturdy

**WORD BUILDING**

osteoporosis: osteon—bone + poros—a passage + osis—condition
assistive devices such as handrails, canes, or walkers should be encouraged as needed. Because of the decreasing density of older bones, fractures not only can result from falls; they can cause falls as well.

EVIDENCE-BASED PRACTICE

Clinical Question
What are the most common causes of falls for residents in the nursing home setting?

Evidence
According to a 2012 Centers for Disease Control and Prevention report on nursing home falls, nursing home residents fall often and repeatedly. Consequences of falls include death or hip fractures and head injuries that can impair quality of life. Causes of these falls are complex and can include muscle weakness, gait and transfer difficulties, hazards such as wet floors, inadequate lighting, bed height too high, medications such as sedatives and antianxiety agents and the 3-day period after changes in these medications, improper shoe fit, or incorrect use of walking aids.

Implications for Nursing Practice
Fall prevention requires a commitment by the organization and multidisciplinary team to plan interventions that look at multiple causation factors including the environment and resident medical treatment and rehabilitation. Interventions can be implemented by patients, staff, multidisciplinary team members, and the organization. Vigilance by everyone is essential to help prevent resident falls.

REFERENCE

BE SAFE!

BE VIGILANT! Reduce the risk of harm from falls with a fall reduction program that includes monitoring of its effectiveness. Assess residents’ or patients’ risk for falls and establish a fall prevention plan. Assessment includes a history of falls, medication review for medications that can cause dizziness, weakness or sleepiness, alcohol use, gait and balance screening, and use of assistive aids. Educate the staff, resident/patient, and family members on the resident/patient-centered fall prevention plan (2014 National Patient Safety Goals, © The Joint Commission, 2013. Reprinted with permission.).

Key Changes in the Integumentary System
Age-related changes in the integumentary system include the following:

• Increased dryness of the skin
• Increased pigmentation, causing liver or aging spots
• Thinning of the skin layers, which makes the skin more fragile
• Decreased skin elasticity, causing wrinkles to develop
• Decreased subcutaneous fat layer, so older patients have less insulation and less protective cushioning
• Hardness and dryness of nails, making them more brittle
• Decrease in nail growth rate and strength
• Thinning of scalp hair, mainly in men
• Increased growth and coarseness of nose, ear, and facial hair
• Decrease in melanin, which results in gray hair
• Decreased sebaceous and sweat glands, which has implications for dryness and decreased temperature regulation.

NURSING CARE. The skin is the first line of defense against infection and injury (Fig. 15.2). In the older adult, skin injuries take longer to heal, and those longer healing times are usually complicated by the fact that many older patients have multiple chronic diseases, such as diabetes and circulatory ailments.

The older patient with limited mobility is especially prone to developing pressure ulcers (Fig. 15.3). These ulcers are caused by ischemia, which results from continuous pressure on an area of the body. They usually develop over a bony prominence (ears, shoulders, elbows, tip of the spine, pelvic bone ridges, knees, heels, or ankles). Ischemia from unrelied pressure can be gin to develop in 20 to 40 minutes. Early signs of pressure ulcer formation are warmth, redness, tenderness, and a burning sensation at the potential ulcer site. These potential ulcer sites are aggravated by lack of activity and the weight of the body. For this reason, it is especially important to take time to assess skin integrity daily, especially in high-risk areas of the body.

BE SAFE!

BE VIGILANT! Assess and periodically reassess each resident’s risk for developing a pressure ulcer and take action to address any identified risks. Educate staff on risk identification and prevention strategies for pressure ulcers (2014 National Patient Safety Goals, © The Joint Commission, 2013. Reprinted with permission.).

Skin care includes gently stimulating nonreddened, intact skin sites with massage, using moisturizing creams regularly (except between toes because too much moisture can lead to infections), refraining from use of electrical heating pads that can burn, and gentle bathing techniques, such as the to wel bath or bag bath, which a void the use of hot w ater, drying soap, and rubbing the skin to dry. The New York Edge Project details techniques for these types of gentle bathing at www.health.ny.gov/diseases/conditions/dementia/edge/interventions/gentle/index.htm. Patients should be taught, if they are able, to shift their weight every 15 minutes when sitting. For immobile patients, consistent repositioning is essential. Ideally, use of pressure-relieving devices or repositioning every 30 minutes is the most beneficial for high-risk patients to help prevent pressure ulcer development (see Chapter 54). Keeping bed linens clean, dry, and wrinkle-free also aids in the prevention of pressure ulcer formation.

As with skin care, nail care is important for older people. Soaking in warm water helps soften nails to ease in their trimming while encouraging blood flow to the peripheral areas of the body. Filing nails with an emery board is safer than cutting nails. To prevent accidental injury to the feet, patients should be instructed not to walk barefoot. Potential pressure points of the feet should be identified and closely monitored, and the patient should be referred to a podiatrist for treatment if there are any concerns. People with diabetes should assess their feet daily because they can have decreased sensation (neuropathy), causing lack of awareness of foot irritation or injury.

Key Changes in the Cardiovascular System

Age-related changes in the cardiovascular system include the following:

• Slowed heart rate
• Decreased cardiac output from less effective functioning of the heart and blood vessels, yielding less oxygen to body tissues
BE SAFE!

BE VIGILANT! Shoes should be checked before putting them on to ensure there is nothing in them that could cause injury if it was not felt and walked on. A person with severe neuropathy wore shoes for 8 hours, into which a tiny toy had fallen and didn’t even feel it. Ulceration developed in the area of the foot where the toy was walked on and hospitalization was required. Teach patients the importance of daily foot and shoe assessment for safety.

- Decreased elasticity of the blood vessels, so the circulatory system is less efficient
- Reduced ability of the heart to quickly increase its rate in response to an emergency because of thickening of the heart valves, left ventricle, and aorta (when rate does increase, the heart takes longer to return to resting rate)
- More arrhythmias (irregular heartbeats), which lead to poor oxygenation of the heart
- Commonly, a lack of classic symptoms of cardiac emergencies
- Increased peripheral vascular resistance in blood vessels, yielding increased blood pressure
- More visible superficial blood vessels of the legs
- Less efficient leg vein valves, creating the risk for an accumulation of excess fluids in the leg tissues.

NURSING CARE. Be a good observer when it comes to caring for older patients because many early symptoms related to circulatory problems are subtle. Cardiovascular disease, which is separate from the process of aging, accounts for half of all deaths in people older than age 65. Older adults must be educated about prevention practices that promote healthy circulation and encouraged to take prescribed medications as ordered. In addition to encouraging oral fluids to balance fluid output in older patients, the nurse must carefully monitor the hazards of fluid overload in all older patients on intravenous therapy.

Special care should be taken to maintain good skin integrity and provide appropriate stimulation. If edema is present in the legs, they should be elevated to promote fluid return to the upper body; supportive, nonrestrictive stockings should be worn as ordered. Concerns regarding leg and foot circulation in the older patient must be identified and reported as early as possible so the primary care provider can order the appropriate arterial or venous therapy to address circulatory concerns before they become problems.

Because quick changes in body position can make the older patient feel weak and dizzy, it is important to stand next to older patients as they dangle their legs over the side of the bed before rising to stand. Changes in body position from lying to sitting to standing should occur gradually to accommodate the less efficient circulatory systems of older patients. Older patients might find comfort in the security of an ambulatory belt or walker if they fear unsteadiness in an upright position. Because falls continue to rank as a leading cause of accidental death in older patients (and because a history of falls remains the key indicator to predict future falls), it is important for the nurse to identify fall risk to determine which older patient might be at greater risk so preventive measures can be documented in the care plan.

Key Changes in the Respiratory System

Age-related changes in the respiratory system include the following:

- Decreased lung capacity
- Weaker cough or gag reflex, increasing the risk of upper respiratory infection
- Reduced tone of lung tissue, so respirations increase to 16 to 25 per minute and are more shallow
- Reduced tone of the diaphragm muscle
- Less complete emptying of the lungs, with greater CO₂ retention
- Decreased blood flow to the lungs, contributing to cardiac arrhythmias.

NURSING CARE. Because the respiratory system is less efficient with advancing age, older patients have a decreased tolerance for activity. Nurses should, therefore, pace activities for older patients instead of letting them confine themselves to bed. The nurse should schedule rest periods to prevent overexertion; however, rest periods should not outnumber the activity sessions planned throughout the course of the patient’s day.

Cough, fatigue, and confusion can be early signs of inadequate oxygen uptake. Respiratory rates greater than 25 per minute can be an early indication of a lower respiratory tract infection. Because overall muscle strength is reduced, the older patient performs the O₂–CO₂ exchange in the less efficient upper lobes of the lung instead of the larger lower lobes specifically designed for this purpose. Because lung recoil strength is decreased, mucus can be more difficult for the older patient to expectorate (cough up). This situation is compounded by the fact that older people also have less effective cough and gag reflexes, which creates greater potential for lung problems.

Because of the normal changes that take place in the respiratory system with aging, it is important to include coughing, deep breathing, and position changes in an exercise program designed to stimulate all lobes of the older patient’s lungs. At the prevention level, encourage the older person to receive a pneumonia vaccination and an annual flu shot. This is important because influenza and pneumo-nia combine to be the fourth leading cause of death in people over age 65. Be aware that lifelong habits, such as smoking and respiratory pollutant exposure in employment settings, secondhand smoke, or paints and glues used in hobbies, are cumulative over time and can contribute to respiratory sensitivity for the older patient. Nurses can help

* WORD * BUILDING *
edema: oidema—swelling
expectorate: ex—out + pectus—breast
prevent the spread of respiratory illnesses by getting flu shots, performing hand hygiene between patients, not exposing patients to any nurses’ illness, and using universal precautions.

**Key Changes in the Gastrointestinal System**

Age-related changes in the GI system include the following:

- Changes in taste and smell, which affect the enjoyment of eating
- Decreased saliva production
- Decreased gag reflex and relaxation of lower esophageal sphincter, increasing the risk of **aspiration** (inhalation of oropharyngeal or gastric contents into the lower airways)
- Delayed gastric emptying
- No functional changes in the small intestine
- Decreased tone in the external sphincter
- Marked decline in liver enzymes, which affects drug metabolism and detoxification
- Decreased peristalsis from generalized weakness of muscle activity
- Alteration in bowel habits

**NURSING CARE.** Many factors can alter appetite, ingestion, digestion, and absorption of nutrients in food, regardless of age. However, the structural and functional changes that occur with advancing age put the older patient at greater risk for not obtaining the nutrients needed to sustain a healthy body system (see “Nutrition Notes—Older Adult Nutritional Needs”).

---

**Nutrition Notes**

**Older Adult Nutritional Needs**

Three areas of nutritional concern for older adults are insufficient amounts of protein, calcium, vitamin D, and vitamin B₁₂. The Recommended Dietary Allowance (RDA) for protein is 46 grams per day for women and 56 for men, amounts found in two glasses of milk and 4.3 to 5.7 ounces of meat, fish, or poultry.

For women older than 50 years and men older than 70 years, the RDA for calcium is increased to 1200 milligrams. For adults older than 70 years, the RDA for vitamin D is increased to 800 International Units (20 micrograms). Both of those nutrients have an impact on bone integrity and can be insufficient in older persons who neither drink milk nor spend time outdoors, and even if they did, their skins are less able to synthesize the vitamin D precursor. To derive the higher RDAs for calcium and vitamin D from milk would require 4 cups of milk for the calcium and 8 cups for the vitamin D. Thus, fortified foods or supplements might be advised.

Achlorhydria (low or absent gastric acid in the stomach) can occur as a result of aging or from chronic ingestion of antacids. In either case, protein digestion and absorption of iron and vitamin B₁₂ can be impaired by the lack of gastric acid and intrinsic factor required for vitamin B₁₂ absorption (see “Nutrition Notes” in Chapter 28). Malabsorption of iron and vitamin B₁₂ can lead to anemia; however, sources of blood loss should also be considered. Because 10% to 30% of older persons malabsorb vitamin B₁₂, its RDA for individuals older than 50 years specifies fortified foods or supplements as the main sources of the vitamin.

Decreased visual acuity and impaired dexterity can make shopping for food and preparing it difficult or even hazardous. Arthritis affects not only mobility, but also jaw movements, so chewing can be problematic. By age 65, about 26% of U.S. residents have lost all their teeth (become **edentulous**) and have to develop skill in the use of dentures. People who need dentures should learn to use them in this order:

- Drinking
- Manipulating soft foods
- Biting and chewing.

Older persons produce less saliva than younger people. The sense of taste declines in most but not all aging patients, who as a result might increase their intake of salt and sugar to the detriment of a prescribed diet plan.

Many older patients are at increased risk for food, nutrient, and drug interactions. Situations associated with these interactions are:

- The use of many drugs, including alcohol
- The need for long-term drug therapy in chronic illness
- Poor or marginal nutritional status.

Identification of any of these factors should prompt a thorough nutritional assessment or referral to a registered dietitian.

Particularly among older people, rigid application of diet rules can be inappropriate. For example, restricting fat by eliminating whole milk and eggs, which are easily eaten and relatively inexpensive, could endanger nutrition in the short term for uncertain long-term benefits.

Little can be done to change the physical alterations in the older body that make getting needed nutrients more difficult. Being knowledgeable and committed to providing the assistance needed to meet nutritional goals is important. Patients should be offered toileting before sitting down to eat. An appropriate amount of time must be provided for the older patient to accomplish the task of eating. If the patient needs help with eating, the nurse must be sensitive to the patient’s pace while giving the patient as much control of the process as possible.

Eating has a strong social component. Encourage the patient to eat out of bed and with others as much as possible, while respecting the patient’s right of refusal to eat in a designated social setting. Some patients might not eat as well when seated next to agitated or confused residents in a common dining hall.
Key Changes in the Endocrine-Metabolic System
Age-related changes in the endocrine-metabolic system include the following:

- Slowing of the basal metabolic rate, requiring a 5% reduction in calorie consumption to maintain weight
- Alteration in hormone production, including changes in estrogen, progesterone, and adrenal secretions
- Decreased pancreatic insulin release and peripheral sensitivity
- Decreased glucose tolerance with advancing age

NURSING CARE. Increased incidence of metabolic disease, such as diabetes, occurs with advancing years. Because of this, older patients should be encouraged to participate in screening programs for early detection of metabolic problems.

Because there is a notable decrease in the effectiveness and interaction of all hormones as one ages, it becomes especially difficult for the older body to respond appropriately to stressful situations. Nurses should spend time addressing the psychological needs of patients by recognizing and addressing actual and perceived stressors that affect their care. Preventive care to keep patients free from the stress of illness is also important.
common in older people (and often more dangerous), nurses must closely monitor not only the quantity of intake and output for older patients but also the quality.

Management of urinary incontinence needs to be tailored to the particular need of the patient. Bladder training programs can be effective when patients are reminded on a regular basis that it is time to urinate. If incontinence results from problems that affect the toileting task itself, such as clothing removal or distance to the bathroom, steps should be taken to eliminate obstacles that stand in the way of continence. Clothing with Velcro fasteners can replace buttons or zippers that are difficult for the patient to manipulate. Urinary briefs can help instill confidence in older patients who previously restricted their activities because of fear of urine leakage. With use of the supportive incontinence brief, assess for early signs of perineal skin breakdown and proper application of the correct type of brief to meet individual needs.

Older patients who are aware of their incontinence might try to inappropriately decrease the chance for leakage by severely limiting fluid intake. This approach often results in dehydration, which disturbs the acid-base and electrolyte balance in the body. Over time, dehydrated patients can have problems with vomiting, diarrhea, weakness, and confusion. Because fluid intake needs to be encouraged in older patients, focus educational efforts on topics such as liquid intake timing and beverage selection (teaching that caffeine and alcoholic beverages should be avoided because they increase urinary output).

In addition, it is important for the nurse to review patient medications and personal medication practices (such as taking diuretics late in the day), which then results in nighttime urination (nocturia) and possible sleep disruption. Teaching perineal muscle support exercises and techniques is successful for some. All patients with unexplained urinary incontinence should be referred to a specialist for further evaluation because it is not a normal condition of aging.

**Key Changes in the Immunological System**

Age-related changes in the immune system include the following:

- Decreased immune response
- Decreased number and function of T cells, leading to impaired ability to produce antibodies to fight disease.

**NURSING CARE.** Older patients tend to have more chronic diseases that can increasingly depress their immune responses over time. Although older patients have fewer colds, they are at higher risk for influenza and other complications once they get a cold. It takes longer to recover from infections, so patients and their family members need to be told that a prolonged recovery is to be expected. It is also important to screen visitors for illness before they visit a recuperating older patient.

Efforts at prevention should focus on teaching the older patient about the importance of obtaining immunizations such as the shingles (a painful, contagious rash caused by the chickenpox virus—varicella zoster) vaccine for those aged 60 and older, reducing stress, eating right, exercising, and maintaining a healthful lifestyle. Those who are immunocompromised (such as those who take steroids) should be aware of the need to take additional safety precautions around others who are ill. Nurses can help patients help themselves by encouraging techniques, such as proper hand hygiene, that support universal precautions.

**Key Changes in the Neurologic System**

Age-related changes in the neurologic system include the following:

- Progressive loss of brain cells
- Decreased blood flow to and oxygen utilization in the brain
- Decreased protein synthesis
- Decrease in sensitivity and the sensation pathways
- Increased reaction times
- Decreased motor coordination
- Decreased equilibrium
- Decreased ability of the hypothalamus to regulate body temperature
- Change in neurotransmitter secretion levels

**NURSING CARE.** Changes in the nervous system of the older patient can be seen in both the peripheral and central systems. These changes have significant meaning for the older person, especially in the area of safety. With normal aging, there is a slowed response to stimuli and a marked decrease in the speed of the psychomotor response to those stimuli. Because stronger stimuli are required to elicit any neurologic response, the older patient is unable to perceive early signs of danger. To protect from accidental skin burns, the thermostat on water heaters should be lowered, and electrical heating devices such as heating pads, electric blankets, and mattress pads should not be used.

---

**CRITICAL THINKING**

**Mr. Jones**

Mr. Jones, age 72, lives at home and is visited by the home health nurse. His home has wood floors with throw rugs. The bathroom is located in the hall outside his bedroom. Mr. Jones has nocturia and is occasionally incontinent from urgency to void. He takes bumetanide (Bumex) 1 milligram orally daily.

1. What additional assessment data should be obtained about Mr. Jones regarding his urinary status and home environment?
2. Are safety concerns present in the home environment?
3. What nursing diagnoses should be included in Mr. Jones’s nursing care plan?
4. What should be included in a teaching plan for Mr. Jones?
5. Mr. Jones is to take bumetanide 1 milligram orally now. Bumetanide 0.5-milligram tablets are available. How many tablets are required?

*Suggested answers are at the end of the chapter.*
Another safety issue of concern focuses on changes in balance. It is more difficult to maintain balance as one ages, especially when musculoskeletal changes are considered. Special caution should be taken to assist older patients with transferring and ambulation activities so optimum levels of safety can be maintained.

Fine tremors of the hand can be a normal finding with advancing age. These movements tend to increase when the older patient is cold, excited, hungry, or active. Assistive devices provided by an occupational therapist (such as handle grips or anchored equipment) can help eliminate the unsteadiness created when fine tremors make it more difficult to accomplish ADLs (Fig. 15.4). Accompanied by generalized muscle weakness, normal neurologic changes that arise with advancing age usually occur on both sides of the body at the same time. One-sided weakness, sensory deficits, and performance problems should always be referred for further evaluation. Coarse tremors of the finger, forearm, head, eyelids, or tongue that occur when the body part is at rest can be a sign of a neurologic problem such as Parkinson’s disease. These typically occur on one side of the body first and should always be referred for further evaluation.

**Key Changes in the Sensory System**
Age-related changes in the sensory system include the following:

- Decreased visual perception
- Decreased elasticity of the eardrum
- Decreased sense of smell
- Decreased taste perception
- Decreased touch sensation

**NURSING CARE.** Sensory changes associated with advancing age tend to occur gradually. Early identification and prompt referral and treatment can sometimes minimize sensory loss, which has a strong impact on the older person’s psychological health.

Normal age-related changes in the eye affect the focus ability of the lens and the maneuverability of the eye muscles to meet the needs of near and far vision. It is especially difficult for older patients to read fine print, although it is usually manageable with reading glasses or bifocal lenses. When caring for a patient who wears glasses, it is important to remind the patient to consistently wear the glasses as needed and to help the patient keep them clean and in good repair. When glasses are removed by the patient, keep them accessible and in a protective, labeled case.

The older patient has a more difficult time adjusting to changes between light and dark settings. Seeing in the dark can be enhanced with the use of a red nightlight because red lighting is more easily detected by the cones and rods in the older patient’s eye. Make every effort to reduce glare from bright sunlight because sensitivity to glare is enhanced by normal changes that occur in the aging eye. The glare from car headlights can impair vision in older patients who are still driving, creating added safety issues with night driving.

Several eye disorders can affect the aging eye (see Chapter 52). Regardless of the cause, any vision loss in older
patients puts them at risk for psychological problems with disorientation, withdrawal, or self-imposed isolation caused by sensory deprivation.

Hearing loss is common in older adults. Although the severity of age-related hearing loss is variable, the stigma it carries is the same. For older patients, the first difficult sounds to discriminate are the high-pitched tones. Therefore, it is often more effective to whisper when communicating with an individual who has a hearing impairment because whispering decreases the pitch of the sounds. Shouting is not helpful because both volume and pitch are increased. It is best to speak to a hearing-impaired person in a moderate volume and a lower tone. It is also helpful to stand in front of hearing-impaired patients so they can see the speaker’s face during communication (Box 15-1).

Two types of hearing loss, conductive or sensorineural, can occur separately or in combination in the patient with a hearing impairment (see Chapter 52). It is important to use hearing protection throughout life because noise damage to the ear is usually not reversible. New-technology hearing aids can help most people with hearing loss. Patients should be referred to an audiologist for further evaluation if hearing loss is suspected. Hearing aids are often not well accepted by older persons or their family members because they are visual signs of a loss. Because of possible sensitivity, it is important to maintain patient privacy if a referral for further evaluation is made. If the older patient has a hearing aid, it should be kept accessible to the patient at all times. The hearing aid should be kept clean with soap and water. A cotton swab removes wax buildup in tiny areas of the hearing aid. When not in use, the hearing aid should be stored in a labeled protective container and the battery turned off to conserve it. Extra batteries should be kept readily available.

As discussed in the GI section of this chapter, the senses of taste and smell work closely together. Like other sensory losses, a declining ability to taste is not a problem exclusive to the older person. Both ill-fitting dentures and poor oral care can contribute to an alteration in the sense of taste, as can certain medications, tobacco products, and oral disease. Because of their codependent nature, taste and smell are two senses often treated as one. Age-related losses are expected to occur gradually in the older patient. In some cases, the loss of smell can result from sinus problems, nasal obstruction, or allergies. If olfactory receptors are the primary cause for losing the sense of smell, little can be done except to teach safety issues related to the loss (e.g., use of smoke alarms and natural gas alarms at home). Because some medications have been linked to the loss of taste, a medication review and daily mouth inspections help the nurse find a source that can be treated. However, any report of sudden loss in taste or smell sensation should be reported to the HCP because it can signal other health care problems.

Nurses also need to be aware of the environment they provide for the older patient. Overstimulation produced by sensory overload (as in intensive care hospital settings) can create psychological and physical strain that is difficult for an older patient to cope with. As a patient advocate, be sensitive to the patient’s environment and changes in the patient’s health care status, identifying and minimizing overload situations early in the recuperation period.

Key Changes in Sexuality

Age-related changes in sexuality include the following:

• Chronic illnesses, which can affect sexual functioning
• Functional sexual changes in older men, commonly alteration in ability to obtain or maintain an erection and to ejaculate
• Functional sexual changes in older women, such as decreased vaginal lubrication
• Sexual problems caused by psychological factors, which are more common than physical ones in older adult patients
• Longer sexual arousal time in the older patient
• Increase in sexual activities that focus on nonintercourse intimacy behaviors, including various forms of touch.

NURSING CARE. The older patient’s sexuality is an important aspect to consider when providing care. It is essential to accept that sexuality is one of the basic physiological needs identified in Maslow’s hierarchy of needs for all people regardless of age. Be aware of personal attitudes and values about sexuality, sex, and aging, being careful that personal stereotypes and beliefs do not interrupt the older person’s attempt to maintain sexual identity. Because privacy remains a common problem for individuals in health care settings, provide the patient some scheduled private time for sexual expression. As new sexual enhancement treatments become more available to patients, there can be a greater openness to discuss sexual expression in conversations with older patients. Still, many older patients have difficulty overcoming barriers to sexual expression because of cultural or religious beliefs, lack of a suitable partner, fear of failure, fear of consequences, illness, side effects of medications, and certain chronic diseases that can alter libido or sexual function. Because sexual discussions with these patients can be more difficult, it is important to address the sexual history section.

Box 15-1 Communicating With Patients Who Have Hearing Impairments

• Ensure that hearing aids are on with working batteries, if applicable.
• Face the patient so the speaker’s face is visible.
• Speak toward the patient’s best side of hearing.
• Speak in a clear, moderate-volume, low-pitched tone.
• Do not shout because doing this distorts sounds.
• Recognize that high-frequency tones and consonant sounds are lost first—s, z, sh, ch, d, g.
• Eliminate background noise because it can distort sounds.
as sensitively, professionally, and completely as other sections of the patient assessment form (Box 15-2).

COGNITIVE AND PSYCHOLOGICAL CHANGES IN THE OLDER PATIENT

Cognition

In addition to the physiological changes that occur with advancing age, older patients also experience changes that have an effect on cognition. Cognition includes abilities related to intelligence, memory, orientation, judgment, calculation, and learning. Cognition focuses on intake, storage, processing, and retrieval of information. For the most part, older patients store information without much conscious effort. If dealing with information becomes difficult, the older person can begin to worry. Unless this worry is addressed, the patient’s concern can result in psychological problems and fears.

Many factors can affect cognition. Sensory changes and diseases associated with age can cause misinterpretation of information being collected. Pain from chronic diseases, such as arthritis, can limit cognition as pain takes over the body and mind. Sleep deprivation caused by worry or fear can make it more difficult to perform routine tasks. Medications that cause drowsiness as a side effect can also impair cognition.

Long-term memory retrieval is easier to accomplish in old age than short-term memory retrieval. Assist the patient having short-term memory problems by using written lists, visual cues, and other memory-enhancing systems to aid in strengthening short-term memory skills.

Intelligence does not decline as one ages if it is measured using an appropriate instrument that focuses on accuracy and not on speed of response. Although cognitive abilities do tend to slow down with advancing age, they are not lost. Most of the subtle declines that occur with information processing and retrieval do not need to interfere with the older patient’s abilities in performing ADLs.

Nurses need to assist in the identification of individual problem situations and work with older patients and their families in developing strategies to better address their needs. It is common knowledge that health, good nutrition, and adequate sleep are important factors for brain functioning. These factors should be the cornerstones in planning care for the older patient.

Coping Abilities

How a person chooses to adapt to a change in functional ability over time has a significant impact on how that person will work through the entire maturational process called aging. In addition to normal aging changes, many older patients are coping with compounding changes that occur because of chronic disease. Nurses must not lose sight of the fact that in addition to changes caused by some decline in physical and cognitive functioning, older persons simultaneously work to deal with many societal and culturally perceived losses associated with advancing age. Changes in employment status and societal and family roles and shifts from independence to dependence can leave a strong psychological impact on both older patients and significant others. With such a combination of losses, an older patient’s confidence level can be affected, requiring encouragement of self-care behaviors.

Personality, attitude, past life experiences, and the desire to adapt to change are all intrinsic influencing factors that help the older patient cope with changes brought on by advancing age. Extrinsic factors include things such as financial status, family support, and support provided by those who directly care for the patient. If older patients have the energy, desire, determination, and support of those who care for them, they are better able to optimize use of their cognitive functions toward health.

Depression

There are times when the psychological impact of change is too difficult to cope with, and loneliness, grief, or sadness does not easily allow the older person to cognitively focus on health. When this happens, depression can result, with the potential to disable the older person’s mind and body. Depression is the most common psychiatric problem among older adults. This psychological condition, which includes a disturbance in mood, increases the risk for suicide, physical health complaints, and sleep disturbances.

Box 15-2 Sexuality Data Collection

As with any nursing skill, practice will increase your comfort in collecting sexuality data for the older patient so these needs are not ignored. Identification of sexuality concerns is a valuable part of data collection, and it also can lead to the discovery of other health issues. Establish rapport with the patient by collecting other data first and turning to sexuality data at the end of the history. Older patients often respond to sexuality questions but will not bring up the topic. As you collect data, be aware of problems (e.g., pain, medication side effects, mobility, dexterity, elimination, angina, surgery) identified in the history that can have an impact on sexual function.

Naturally, you should use a professional approach and manner and tell the patient that you will now ask questions about sexuality. Start with questions that are likely to be more comfortable for the patient, as follows:

- Address roles first. For example: What concerns (do you have or has your illness created) in carrying out your roles with your (spouse or sexual partner)?
- Address relationship issues next. For example: What effect on your relationship with your (spouse or sexual partner) has this (illness, symptom, chronic illness) had?
- Address body image. For example: What effect has your (illness, surgery [mastectomy, prostate, ostomy], chronic illness, age-related changes) had on your self-concept of being a (man or woman)?
- Address sexually transmitted infections. For example: Do you have any discharge or open sores (vaginal, penile)?
It is important to understand that the frequency and intensity of depression generally increase with advancing age. Depression can result from physical changes in the brain, as from a medication or a condition affecting neurotransmitters, or from psychological changes at an emotional level, such as maladaptive coping from a perceived loss. Regardless of the cause, depression has the potential to be reversed with prompt identification and treatment. It is important, therefore, to be sensitive to what the older person is and is not saying during communications. If depression is suspected, patients should be referred for treatment before maladaptive behaviors occur.

Dementia

Unlike depression, dementia involves a more permanent progressive deterioration of mental function. Dementia is often characterized by confusion, forgetfulness, impaired judgment, and personality changes. There are two main types of dementia: multi-infarct dementia and Alzheimer’s disease.

For dementia, help the older patient maintain an optimum level of functioning in an atmosphere that provides physical and emotional safety. To help ground the confused patient, if appropriate, incorporate reality orientation or validation into all nursing interventions. Sensory overload should be decreased for confused patients. Speak calmly and slowly, and provide nontreating therapeutic touch if accepted by the patient.

In addition, it is important to address the education and support needs of the patient’s family as they learn to deal with changes in the older patient’s behavior. Refer any patient with confusion for a mental status examination to help determine whether the person has depression or dementia. It is essential that a sensory status examination be conducted before a mental status examination to help ensure the accuracy of the test results.

Delirium

Delirium reflects the patient’s level of alertness and psychomotor activity and is commonly a complication of acute illness and its treatment. Although it can occur in hospitalized patients at any age, it occurs most often in hospitalized older patients and is often charted as “confusion.” Although the actual mechanism through which delirium occurs is not known, it is thought to stem from changes in brain neurotransmitters that control cognitive function, mood, and behavior. Unlike depression and dementia, delirium has a sudden onset, tends to be worse at night, and can last for a few hours or a few weeks. The patient seems disturbed or frightened. Based on patient behaviors, delirium can be classified as hypoactive, hyperactive, or mixed.

Also different from depression and dementia, delirium is a cognitive state that can be easily reversed once the cause is identified and treated. For this reason, the nurse must not assume that the older patient’s current mental status is his or her usual state. The nurse must be able to identify risk factors for this condition (e.g., acute illness, infection, alcohol or other drug abuse, surgery, hip fracture, metabolic disturbance) and report any patient concerns before they become problems.

Sleep and Rest Patterns

The need for sleep does not decrease with age, but the pattern in older adults usually varies from earlier times in their lives. As in any age group, lack of sleep leads to fatigue, irritability, increased sensitivity to pain, and increased likelihood of accidents. This is why it is important to obtain a baseline sleep and rest history when an older patient is admitted to a health care unit. Consider sleep patterns, bedtime rituals, rest and nap patterns, daily exercise patterns, stress level, dietary intake patterns, and lifestyle issues such as caffeine, alcohol, and nicotine intake when completing a sleep and rest assessment for an older patient.

Circulatory problems can disrupt normal sleep patterns for the older person and might be the only clue of an impending health problem. The anxious patient who is unable to sleep might be calmed with back rubs, foot rubs, a warm towel bath, warm milk, or a glass of wine, if not contraindicated, when patterned bedtime rituals prove to be unsuccessful. Sleep medications should be used only as a last resort because they can affect the quality or depth of the sleep the older person receives and can produce unwanted side effects.

Medication Management

Medication management is one of the most difficult tasks for older patients, family members, and the health care providers caring for them. Because older patients are more susceptible to drug-induced illness and adverse side effects for a variety of reasons already addressed in this chapter, nurses need to be especially aware of what the older patient is taking, how it is being taken, and its effects. The Beers Criteria updated by the American Geriatrics Society identifies potentially inappropriate medication use in older adults (The American Geriatrics Society, 2012) (Table 15.2).

Older adults often have more than one chronic illness for which they take multiple medications. Polypharmacy can result in side effects that can be dangerous or duplication of medications with similar actions. Not only do HCPs need to be aware of prescribed medicines; they also need to review all over-the-counter medicines and self-prescribed extracts, elixirs, herbal remedies, herbal teas, cultural healing substances, and other home remedies that are being used by the older adult.

HCPs not only need to be concerned about overuse and combinations of medications but also misuse of them. If an older patient crushes a large enteric-coated pill so it can be taken in food and easily swallowed, destruction of the enteric protection can inadvertently cause damage to the stomach and intestinal system. Some patients intentionally skip prescribed doses as a way to save money. When prescribed doses are not being taken as expected, problems do not clear up as quickly, and new problems can result.

Be a patient advocate by working closely with older patients and their families on medication education. Patients need to know the purpose of each prescribed medicine, the importance of adherence to medication therapy, when a medication should be taken, how it should be taken, what food–beverage–medicine combinations are not safe, and the early and late side effects of the medicine that must be reported to the physician (see “Evidence-Based Practice”).

Chapter 15 Nursing Care of Older Adult Patients 289
TABLE 15.2 MEDICATIONS AND GERONTOLOGICAL ISSUES

<table>
<thead>
<tr>
<th>Ten Medications to Use With Caution or Avoid in Older Adults</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Caution: Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) Avoid: Long-acting NSAIDS (indomethacin, piroxicam)</td>
<td>Increases risk of indigestion, ulcers, bleeding in stomach or colon. Increases blood pressure, worsens heart failure, impairs kidneys.</td>
</tr>
<tr>
<td>Avoid: digoxin (Lanoxin) greater than 0.125 mg</td>
<td>Can become toxic in older adults and those with impaired kidney function.</td>
</tr>
<tr>
<td>Avoid: glyburide (Diabeta, Micronase), chloropamid (Diabinese)</td>
<td>Can cause severe low blood sugar.</td>
</tr>
<tr>
<td>Avoid: Muscle relaxants such as cyclobenzaprine (Flexeril), methocarbamol (Robaxin), carisoprodol (Soma)</td>
<td>Can cause grogginess, confusion, increase fall risk, constipation, dry mouth, urination problems.</td>
</tr>
<tr>
<td>Avoid: Medications for anxiety/insomnia such as benzodiazepines, including diazepam (Valium), alprazolam (Xanax), chlordiazepoxide (Librium); sleeping pills such as zaleplon (Sonata), zolpidem (Ambien)</td>
<td>Increases confusion, fall risk, and prolonged grogginess and sleepiness.</td>
</tr>
<tr>
<td>Avoid: Anticholinergic drugs such as amitriptyline (Elavil), imipramine (Tofranil), trihexyphenidyl (Artane), dicyclomine (Bentyl), oxybutynin (Ditropan)</td>
<td>Can cause blurry vision, low blood pressure, confusion, constipation, urination problems (caution with enlarged prostate).</td>
</tr>
<tr>
<td>Avoid: Demerol</td>
<td>Increases risk for seizures and confusion.</td>
</tr>
<tr>
<td>Avoid: antihistamines diphenhydramine (Benadryl), chlorpheniramine (AllerChlor, Chlor-Trimeton)</td>
<td>Can cause blurry vision, confusion, constipation, dry mouth, urination problems (caution with enlarged prostate).</td>
</tr>
<tr>
<td>Avoid unless prescribed for psychosis: haloperidol (Haldol), risperidone (Risperdal), quetiapine (Seroquel)</td>
<td>Increases risk of stroke or death. Causes tremors, other side effects, increase fall risk.</td>
</tr>
<tr>
<td>Avoid: Estrogen pills and patches</td>
<td>Increases risk for breast cancer, blood clots, dementia.</td>
</tr>
</tbody>
</table>

Medication use, abuse, and misuse need to be addressed regularly with older persons. Concerns need to be closely monitored and promptly addressed. Older patients can be helped to adhere consistently to a prescribed medication routine through the use of visual and verbal reminders that have meaning for the patient. Encouraging proper medication use, self-care, and supportive independence helps everyone involved in the patient’s medication management.

EVIDENCE-BASED PRACTICE

Clinical Question
Can medications be taken with grapefruit juice?

Evidence
Research studies have shown that the chemicals found in grapefruit juice and pulp (as well as some bitter oranges used to make orange marmalade) can interfere with the enzyme activity needed to break down some drugs in the digestive system. This can result in overly high levels of some drugs that can cause serious side effects and toxicity (Dolton, Roufogalis, & McLachlan, 2012).

Implications for Nursing Practice
Because grapefruit and some bitter orange citrus fruits can interfere with safe drug absorption, they should not be used with some medications until after approval by the pharmacist.

REFERENCE
Condition, needs, and strengths. Listening and observing are two key nursing skills required to accurately obtain information from older patients because symptom patterns often differ between younger and older patients with the same health conditions. For example, older patients can have confusion rather than chest pain during a heart attack.

Health education is the most important health promotion tool for the nurse to use in the care of older patients. Educational efforts must first focus on erasing stereotypes about aging and erroneous associations between aging and illness. (For example, although research shows that urinary incontinence is not a normal sign of aging, many still think it is inevitable with old age.) Providing evidence-based health information at the right time, in the right amount, and in the right way can empower the older patient to value a proactive approach for wellness in old age. Once a health promotion approach is accepted, the nurse can work with the older patient in health screening, immunization updates, safety program participation, and activity planning aimed at an optimal level of functioning and wellness for the older patient (Table 15.3).

BE SAFE!

BE VIGILANT! For medication safety:
- Document a complete list of the patient’s medications on admission by actively questioning the patient and family members.
- Make sure newly prescribed medications are compatible with the patient’s current medications and reviewed by a pharmacist.
- Use at least two patient identifiers other than room number, such as patient name and birth date, when giving medications.
- Before the patient goes home, provide a complete written list of medicines and doses to the patient, family members, and the next caregiver or physician.

HEALTH PROMOTIONAL ROLE IN NURSING CARE OF THE OLDER PATIENT

Before the nurse is able to focus on health promotion and disease prevention, it is important to accurately determine the present health status of the older patient. When gathering holistic health data, the nurse focuses on the older patient’s mind, body, and spirit, separately and in combination. Care must be taken to use valid and reliable data collection tools during this process to gain a true picture of the older patient.

TABLE 15.3 NURSING CARE FOCUS ON SAFETY ALPHABET FOR OLDER PATIENTS

| A is for ABILITIES | • Know your abilities.  
|                   | • Know patient’s abilities.  
|                   | • Base nursing actions on your abilities.  
|                   | • Seek out assistance when needed.  |
| B is for BODY MECHANICS AND ALIGNMENT | • Use proper body mechanics.  
|                                         | • Use appropriate assistive devices.  
|                                         | • Ensure patient is in proper body alignment.  |
| C is for COMFORT | • Ensure physical and emotional comfort during care.  
|                 | • Use pain scale during each assessment.  |
| D is for DELIBERATE MOVEMENTS | • Plan ahead and communicate plans to patient.  
|                               | • Demonstrate confidence during care.  
|                               | • Alert patient to planned movements by saying, “Moving on three. One, two, three.”  
|                               | • Ensure patient assists with moves as able.  |
| E is for ENVIRONMENT | • Always place call light within reach.  
|                   | • Keep environment uncluttered and safe.  
|                   | • Ask patient’s permission before moving items.  
|                   | • Put items back as patient prefers.  |

Gerontological Issues

Playing Nintendo Wii games such as bowling can be an enjoyable activity for the older adult. It can provide socialization, exercise and diversion to reduce boredom and loneliness. It is being used in settings such as long-term care.

</table>

Home Health Hints

**Home Visits**
- Schedule therapy visits and nurse visits on the same day, if possible, to decrease the risk of fatiguing the older patient.
- Because many older patients keep their homes warm, wear layers of clothing, removing a layer as needed, rather than adjusting the heat in the home.
- Place cell phones and pagers on a silent mode, if possible, to avoid startling or confusing the older patient.
- Do not assume that the older patient will remember the health care nurses who come to the door. Each time, state your name and why you are there. Wear a large-letter photo nametag that is in clear view.
- To enhance the effectiveness of a visit, ask the older patient to talk in a quiet room of the home with the main caregiver invited in at the appropriate time. This can help the older patient stay more focused while ensuring privacy and fostering the person’s ability to hear.
- Stressors in a patient’s life, such as annoying visitors, chastisement by caregivers, and harassment by bill collectors, are often experienced firsthand by the home health nurse. Document and share those with the home care team, so a coordinated approach can be taken.

**Medications**
- Assist patients and/or caregivers with obtaining and setting up a weekly pill dispenser. These can be purchased at the local pharmacy. For patients who are forgetful, a pill dispenser with a timer can be purchased. An audible or visual alarm will go off when it is time for them to take medications.
- It is important for the home health nurse to assess the patient’s ability to follow instructions. During visits, check the medication dispenser to ensure that pills are being taken as prescribed. If there is a concern, inform the primary care provider.

**Nutrition/Fluids**
- One of the first signs of dehydration is tachycardia. Instruct the patient regarding adequate hydration.
- If the older patient has dentures, assess if they are worn for eating. If not, assess why they are not worn (e.g., sores, improper fit from weight loss) and discuss solutions.
- Check the refrigerator for outdated food. Many older patients are on a limited budget and have been taught not to waste food. These factors, along with a decreased sense of smell and taste, can increase the risk of food poisoning.
- Encourage the use of spices and herbs, such as parsley, oregano, lemon, garlic, and basil, instead of salt and sugar. Suggest keeping pared apples and segments of oranges in the refrigerator for snacks.
If a Meals-on-Wheels program is available, ask if the older patient would like to be placed on the service.

Use a warming tray when feeding an older patient who takes a longer time to eat.

When swallowing is difficult, freezing of liquids helps, so they can be eaten with a spoon or like a popsicle. Milkshakes, high-protein drinks, instant breakfast mix, or eggnog are thicker liquids that are easier to swallow.

Elimination

If an older person wears perineal pads or adult briefs, ask how many are used in a 24-hour period to assess the degree of incontinence or amount of output. Have the patient keep a voiding diary to further assess the degree of incontinence.

Suggest a bedside commode when a weakened older patient is on diuretics or has a history of falling or confusion. Placing it next to the bed at night helps reduce the risk of falls and eases caregiver burden.

If the older patient reports constipation, review the diet and make suggestions regarding adequate fluid and fiber. A mixture of equal parts of applesauce, bran, and prune juice is often helpful to prevent or relieve constipation. Discourage the use of mineral oil because it will interfere with vitamin absorption.

Rest

If the older patient seems fatigued early in the day, ask about sleeping patterns and things that disturb it, such as barking dogs, traffic noise, and visitors. Recommend earplugs or changing rooms to obtain a good night’s rest. Check medications for insomnia listed as a side effect and suggest dosing of these medications early in the day if appropriate. A 15- to 30-minute nap in the early afternoon can be helpful.

Infection Symptom

One of the first signs of infection in the older patient is confusion.

Education

Suggesting that limiting visitors or not allowing persons with colds to visit can be helpful in preventing illness in the older patient.

When auscultating lungs, ask the older patient to take deep breaths slowly in and out through the mouth. This can stimulate coughing, which is an opportune time to teach deep-breathing and coughing exercises.

When teaching, it is important to acknowledge the patient’s knowledge and life experiences. When given a chance, patients tell how they have maintained their health over the years. Use open-ended scenarios for teaching such as, “What would you do if you fell and you were alone?”

Teaching should occur with patients, not to them. The nurse is in the patient’s home, which is a personal place. Patient dignity should always remain intact during home care visits and teaching sessions.

Lab Draws

When drawing blood from the hand of an older patient, use the smallest needle possible and a butterfly device. Hold light pressure at the injection site for at least 2 minutes after the needle is removed.

Do not use a bandage on the fragile skin of an older patient if the bleeding has stopped with pressure.

SUGGESTED ANSWERS TO CRITICAL THINKING

Mr. Jones

1. Does he live alone? Does he have a history of falls? If so, does he wear a safety device to signal for help? What type of nightlight is used? How far is it to the bathroom? Does he take his bumetanide (Bumex) early in the day rather than at night? Does he void before going to bed? Does he anticipate needing to void 30 minutes after lying down?

2. Wood floors that are slippery when wet from incontinence are a safety hazard. Throw rugs can slide or cause tripping. An appropriate nightlight should be available.

3. Nursing diagnoses include Functional Urinary Incontinence related to distance to bathroom; Deficient Knowledge related to safety, medication administration, and nocturia; and Risk for Injury related to slippery floors from incontinence, use of throw rugs, and inadequate lighting.

4. A teaching plan should include the following:

   • Safety: Place urinal at bedside to prevent incontinence on way to bathroom. Consider red nightlight to improve vision and prevent falls. Use easily cleaned floor covering that is secure and absorbent to avoid falls. Consider the need for wearing a device that can send a signal for help.

   • Medication administration: Take diuretics early in the day to avoid having to get up frequently while sleeping at night.

   • Nocturia: Void before lying down. Anticipate need to void after lying down by reclining in chair for 30 minutes with legs elevated before going to bed and then void on way to bed.

5. Two 0.5-mg tablets.
UNIT THREE  Understanding Life Span Influences on Health and Illness

REVIEW QUESTIONS

1. When planning care for the older adult, the nurse understands the definition of aging as being which of the following?
   1. A disease state that results in the death of a person’s body cells all at once
   2. A condition that starts for all people when they reach the age of 65
   3. A maturational process with individual adaptations for physical and psychological changes over time
   4. A state of accelerating decline in body functioning directly related to a disease process

2. The nurse is collecting data on a patient who is 77 years old and says, “I am shorter now.” The nurse would recognize that which of the following commonly contributes to individuals becoming shorter with age?
   1. Contractures
   2. Bone degeneration in the legs
   3. Hyperextension of the cervical spine
   4. Water loss from the intervertebral disks of the spine

3. Which of the following interventions should the nurse perform to protect skin integrity in the older adult? Select all that apply.
   1. Assess skin daily
   2. Apply moisturizer between toes
   3. Use gentle bathing techniques
   4. Gently massage nonreddened, intact skin sites
   5. Use hot water for bathing

4. Which of the following is the best approach for the nurse to use with a cognitively alert older patient recently diagnosed with hypertension that would help encourage prescribed antihypertensive medication compliance?
   1. The nurse says, “It is important that you take your blood pressure pill every day. Do you understand this?”
   2. The nurse explains the medication and gives the patient a grid to record daily when the pill is taken. The nurse then asks, “How do you see this working for you?”
   3. The nurse asks the patient, “Do you have a relative or friend who can call you every day to remind you to take your blood pressure pill? It is really important that you take it and as you get older it is harder to remember things.”
   4. The nurse tells the patient, “If you don’t take your blood pressure pill, you will probably have a heart attack or a stroke, so you better figure out a way that you don’t forget to take it everyday.”

5. The nurse contributes to the plan of care for an older patient on bedrest based on the understanding that pressure ulcers occur at sites of ischemia and can begin to develop as early as which of the following time frames?
   1. 5 to 10 minutes
   2. 20 to 40 minutes
   3. 50 to 60 minutes
   4. 75 to 120 minutes

6. The nurse is planning care for an older patient at risk for aspiration. Which of the following does the nurse understand would place the older patient at greater risk for aspiration?
   1. Increased lung capacity
   2. Decreased lung capacity
   3. Decreased gag reflex
   4. Increased gag reflex

7. Which of the following actions could the nurse institute to help prevent constipation in the older adult patient? Select all that apply.
   1. Increase dietary fiber intake.
   2. Decrease water intake.
   3. Encourage participation in ADLs.
   4. Review medication effects.
   5. Increase daily exercise.
   6. Decrease fresh fruit intake.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Describe how the history of home health nursing has shaped the nursing care of today.
2. List the members of the home health team and their roles.
3. Compare and contrast hospital-based nursing care and home health nursing care.
4. Explain the steps involved in making a home health visit.
5. Explain safety practices for the nurse while making home visits.
6. Identify home safety interventions for the patient.
7. Describe methods of infection control the home health nurse uses.
8. Identify what is to be included in documenting a home visit with a patient.
9. Plan nursing interventions for the home health patient and caregiver.

INTRODUCTION TO HOME HEALTH NURSING

What do you think home health nursing care is? It is health care conducted in the home by qualified nurses. It is an important component of patient care. The Bureau of Labor Statistics (2012) indicates that there will be a 22% increased need for licensed practical/vocational nurses (LPN/LVNs) from 2010 to 2020. This increase in need will lead the LPN to positions in home health. Part of this increase is due to the aging baby boomer population (those born between 1946 and 1964) who will develop functional disabilities, patient preference for care in the home, and technological advances that are making complex care in the home cost-effective. LPN/LVNs need to understand how care is received in the home because the hospital and home settings differ.

HISTORY OF HOME HEALTH NURSING

Home care is not a new concept. Nurses have been caring for patients in their homes for more than 100 years. In 1893, Lillian Wald set out to improve the New York community in which she lived. Health care was available only to those who could afford it. Because of limited access to health care and lack of education, the home environment that poor families and immigrants were living in was not conducive to health and wellness. With the help of fellow nurse Mary Brewster, Wald established the Henry Street Settlement in New York City. The services started by Wald and Brewster laid the groundwork for establishing home care as a nursing specialty. Because of Lillian Wald and the nurses who worked with her, families were able to receive care and education in their homes to maintain or improve their health (Friends of Mt. Hope Cemetery, n.d.).

During the early 20th century, nurses took the initiative to develop community programs to meet the needs of the patients in their care. Nurses in the 21st century can learn from this and be involved in improving the communities in which they live. Home health nurses focus not only on the patient but also on the patient’s family and the community. In home health care, nursing care and its differences from medical care can be truly understood.

HOME HEALTH ELIGIBILITY

Home health care requires skilled nursing care and must be delivered by a licensed professional nurse. Physical therapy and occupational therapy may also be needed, independent of nursing. A patient who is receiving home health nursing is required to be home bound. If patients are able to drive, then it is felt they are able to transport themselves to health care services. Patients are also viewed to attend special events, go to church, or go to medical appointments and still be considered homebound. If the nurse suspects a patient is driving daily, he or she needs to reinforce eligibility for home health and suggest alternative options for health care to permit the patient to maintain independence. These options can include activities such as going to a clinic to have a blood pressure reading done, attending an outpatient physical therapy or occupational program, or having skilled needs (such as dressing changes) completed in a day surgery facility. If you have concerns about a patient, discuss them with the registered nurse (RN), who can work to assist the patient in receiving the needed care.

Home health services usually are ordered for care after discharge from the hospital when there is a need for skilled care in the home. Skilled care includes those skills that patients cannot complete alone and that require the interventions of a qualified nurse (Box 16-1).

It is not uncommon, however, for a health care provider’s (HCP’s) office to request home health services after seeing a patient in the office. For example, a patient who is having difficulty controlling blood glucose levels could benefit from having a nurse come to the home to assess how the patient is using a glucometer and what types of food are being purchased, to monitor the glucose level, and to teach the patient appropriate diabetic management. Another

Box 16-1 Skilled Activities for the Home Health Nurse

According to the Centers for Medicare and Medicaid (2011), which is the agency responsible for establishing home health rules and guidelines, a visit is considered “skilled and necessary” when the patient cannot perform the needed skill, there is no family member available to perform it, and the patient’s medical issues make it necessary to have a licensed professional nurse monitor and manage the situation. Examples of skilled activities include:

- Dressing changes
- Administration of IV medications
- Management and assessment of newly inserted feeding tubes and tracheostomies
- Management and assessment of a new colostomy or urostomy
- Foley insertion and maintenance
- Patient and family education
- Monitoring a patient’s status following a change in medications or condition
- Blood draws (only if the patient is receiving other home health services; this is not covered as an independent skilled visit)

If a family member is present and able to perform the skill part of the time, the nurse can teach that person how to perform the skill. The nurse may still complete skilled visits to monitor patient progress and attend to the patient’s needs when family members are not available. It is important to remember that a skill must be involved, as discussed earlier. If the patient can manage the care either independently or with help from a family member, the services of a home health nurse may not be required.
example would be patients who cannot easily get to the HCP’s office to have their blood pressure checked weekly. If the HCP has changed the patient’s medications, he or she might need to make sure the adjustment is improving the patient’s health as demonstrated by stable blood pressure readings. These types of visits are usually short term with the goal of facilitating independent care by the patient and/or family.

**OTHER MEMBERS OF THE HOME HEALTH TEAM**

**Social Services**

Based on recommendations from the RN or hospital case manager, the HCP may order a social worker to evaluate community resources to assist the patient. Social services can be helpful in creating a link between the patient and resources available within the community. These resources can include meals on wheels, safety resources, or outreach programs.

**Assisted Living Facilities**

Home care may be provided in an assisted living facility for patients living in this type of facility. Because these facilities are not skilled nursing facilities, the facility staff is not able to perform nursing skills. Home health nurses need to understand the facility’s policies when visiting a patient in assisted living and maintain communication with the facility staff regarding health care instructions (e.g., keep the dressing clean and dry).

**CRITICAL THINKING**

Mr. Rosa

- Mr. Rosa, 75 years old, was just discharged from the hospital following an acute exacerbation of heart failure. You notice that he has little food in his house. It appears that the home has not been cleaned in several weeks and that the clothes he is wearing are torn and soiled. Talking with him, you learn that his wife died 6 months ago from cancer and he has had a difficult time adjusting to this loss.

1. What are some community services that might be available to Mr. Rosa?
2. What information would be important to discuss with Mr. Rosa’s HCP?
3. Are there any other services that the home health agency can offer Mr. Rosa for patient centered care?

Suggested answers are at the end of the chapter.

**TRANSITION FROM HOSPITAL-BASED NURSING TO HOME HEALTH CARE**

When working in the hospital, the nurse has many resources available, including resource staff such as other nurses, HCPs, respiratory therapists, and unit secretaries. Patients who enter the hospital are leaving behind the comfort of their own homes. They may be scared and isolated, trying to adjust not only to an illness but also to a new environment. The opposite is true in home health nursing. In the patient’s home, the nurse is the visitor. There is no resource staff to answer questions, and the surroundings are unfamiliar. This can be a difficult adjustment for the nurse. As your confidence in being a home health nurse grows, so too will your comfort level with entering someone else’s home.
Cultural Considerations

In the Hispanic culture, families may be large and their living spaces may be small. When you first enter such a home, you may have a feeling that the lack of space is unhealthy. It is important to realize, however, that this is part of the Hispanic culture. You must evaluate the overall home environment, not just its appearance. Chapter 4, “Cultural Influences on Nursing Care,” offers further discussion of transcultural nursing care.

It is important to remember that you have entered another person’s home. Cultural issues need to be recognized and considered (see “Cultural Considerations”). Do not make quick judgments because the dishes are not done or the bed is not made. People have different values that may not always match yours. If the home is in such a state that it poses a health or safety risk, then it might be necessary to inform the RN.

Resources are not always quickly available when working in a patient’s home. As such, it is important to have a good understanding of nursing skills. Home health nursing requires an ability to adapt and remain flexible because the home environment, unlike the hospital environment, can be unknown. Because of this, it is necessary to assess both the patient and his or her home setting.

Consider the patient who has been referred to home health services after a fall at home and subsequent fracture of an arm. The referral was to start physical therapy services, not skilled nursing. During the initial assessment, the nurse notes that the patient is lethargic and has extremely low blood pressure readings upon standing. Further data gathering of the home environment leads the nurse to find that the patient’s wife has been giving too much of the patient’s heart medication. The home health nurse can contact the supervising RN to obtain orders from the HCP to assess the patient’s blood levels of this medication. This example demonstrates how nurses in the home need to evaluate the patient’s case based not only on the referral diagnosis but also on what can be occurring within the home that could have contributed to that diagnosis.

Families play a large part in the care of patients in the home. Do not be surprised to walk into a home and find several anxious family members with a list of questions they would like answered. They will be very involved in your visits. This can be intimidating at first. When preparing for a visit, take the time to review and learn about an unfamiliar diagnosis or medication. Also be prepared for the unexpected. Carry extra common supplies such as various sizes of urinary catheters, sterile dressing gauze, different types of tape, and lots of alcohol wipes. This will help you feel more prepared and assist with developing a helping, trusting relationship with your patients and their families.

Because of the autonomous, or independent, nature of home health, most agencies require at least 1 year of medical-surgical nursing experience. This helps ensure that you have gained the basic knowledge needed to work in home care. You will continue to learn as you work in the home setting. Home health agencies also hire nurses for specialty areas such as cardiac or wound care. Nurses with a specific specialty will usually work with patients who have diagnoses within their specialty. See Box 16-2 for a review of liability issues.

THE ROLE OF THE LPN/LVN IN HOME HEALTH

The LPN/LVN’s role in home health is varied and complex. Skilled care may be similar to those performed in the hospital setting, such as wound care, or medication administration (Fig. 16-2). The difference is the setting in which these skills are performed. Many factors need to be considered when

Box 16-2 Liability Issues to Consider When Working in Home Health Care

When starting in home health care, review your state’s nurse practice act and your scope of practice. The National Council of State Boards of Nursing (www.NCSBN.org) lists all the state boards of nursing Web sites. This is a useful tool for any nurse.

Understanding your scope of practice will ensure that you complete care that follows your state’s guidelines. When in patients’ homes, they might ask you to perform a skill or request something that is outside your scope of practice. It is important that you explain to them that it is outside your scope of practice but still address their concern by contacting your agency immediately to find out how to handle their request. It is important to address their request because it could indicate a change in the status of their health.

For example, if a patient asks you if it is okay to increase a medication, you should understand that as an LPN/LVN, you cannot prescribe medications. So if you were to say it was okay, you would be altering the prescribed dose, and thus practicing outside your scope of practice because only an HCP can prescribe medications.

Always discuss your concerns with your supervisor and review your agency’s guidelines, policies, and procedures. Know what you can and cannot do before you start, and never be afraid to question something that you feel or know violates your nurse practice act. Remember: It is your license, so follow your nurse practice act!
assisting patients in the home (e.g., having necessary supplies, infection control, patient education material, documenting, and personal and patient safety).

**STEPS IN THE HOME HEALTH VISIT**

**Preparing for the Visit**

A typical day for the home nurse consists of six to seven home visits. These visits typically last 30 to 45 minutes. Most agencies try to arrange visits in the same geographical location for convenience. If your visits are focused on a specialty such as wound care, you may have to travel long distances to visit your patients, but then you would be assigned fewer than seven visits. Agencies allow for mileage reimbursement, so be sure to keep close track of mileage from house to house.

The night before your visit, develop a plan of action for how your visits will be structured. Sometimes you will need to be at a certain place at a particular time, so factor this into your planning. Each patient needs to be contacted. Give the patient a 1- to 2-hour window for your arrival time. Remember, you cannot always anticipate what is going to happen during a visit. It is better to give your patients a time range as opposed to an exact time. If you are unsure how to locate your patient’s home, ask for directions while you are arranging the visit time.

The agency will usually provide you with a form to use that reviews the patient’s diagnosis, pertinent medical information, and reason for home health care. Writing directions to the patient’s home on these forms is an easy way to have the information close by. It is important for this process to be organized. If you have too many papers with information on them, it is difficult to manage both your time and the patient’s needs, creating frustration for all.

**LEARNING TIP**

Map sites on the Internet are a great place to find driving directions (see [http://maps.google.com](http://maps.google.com) or [www.mapquest.com](http://www.mapquest.com)). Simply type in starting and ending addresses to obtain detailed directions. Carry with you a map and cell phone—even the best of directions can be confusing once on the road. GPS apps are now available that the nurse can download to a cell phone, which will provide step-by-step instructions while driving.

If you are going to be late for any reason, contact the patient. Remember, these patients are homebound and often anxious. Arriving late can interfere with development of an effective therapeutic relationship.

**Safety Considerations**

Home health nurses’ travels can take them to areas that are dangerous. It is important to be vigilant about personal safety.

Box 16-3 lists tips on how to protect yourself before, during, and after a home health visit. Patient safety in the home is also of importance. Stay alert to things in the home that can pose a hazard to the patient. Teaching the patient how to prevent injuries in the home is an essential intervention. Physical or occupational therapy can help the patient build strength, learn how to use assistive devices, and maintain safety. “Gerontological Issues” offers some ideas for patient safety considerations in the home.

**Gerontological Issues**

Older adults make up a significant proportion of home health patients. Because of changes in their health, many items in patients’ homes can become potential safety hazards. The home health nurse should always assess the patient’s safety in the home. Things to look for are as follows:

- Overcrowded spaces
- Scatter/throw rugs
- Bathroom safety
- Adequate lighting
- Access to needed supplies
- Steps to enter the home
- Pets
- Electrical cords
Box 16-3 Safety Guidelines for Home Health Nurses

In general, providing home health services is a safe occupation. Most communities recognize the importance of the role of home health nurses and are receptive to their visits. It is still important to understand how you can protect yourself in case an unsafe situation arises.

Here are some tips for maintaining safety when completing a home health visit:

- Always carry a map, whistle, and cell phone.
- Keep your gas tank filled.
- Complete recommended maintenance on your car and have the tires checked regularly.
- If possible, park on the street or road in front of the house. This prevents someone from blocking you in the driveway.
- When entering a home, be aware of where the exit doors are and any windows that will allow safe evacuation from the home.
- Be aware of your outside surroundings. When leaving the home, have your supplies packed up and keys out, ready to open the car door.
- If lost in an unknown area, leave and go to a familiar place and contact the patient for directions. Call your agency if you are concerned about home safety.
- If you need to complete a visit at night, request an escort. Many communities will have a police officer accompany you to and from the home. Discuss this option with your supervisor.
- Never complete a visit if you feel concerned for your safety.

CRITICAL THINKING

Mrs. Ambani

Mrs. Ambani was referred to your home health agency after an appointment with her HCP. During that visit, Mrs. Ambani was diagnosed as being anemic, resulting in dizziness, fatigue, and alterations in her blood pressure. The HCP requested home health nurse visits for Mrs. Ambani to assess her safety and recommend appropriate safety devices.

1. What are some safety devices that would assist Mrs. Ambani?
2. What are some hazards in the home the nurse should look for?
3. Visit www.champ-program.org and identify fall prevention tips from the fall prevention toolkit to plan care for Mrs. Ambani.

Suggested answers are at the end of the chapter.

Infection Control

Maintaining asepsis in the patient’s home may be a challenge. The home health agency will review infection control policies and procedures during in-service orientation. In the hospital, everything is available for infection control. In the home, the nurse is responsible for bringing supplies, provided by the home health agency, for safe care. Periodically go through your equipment supply to make sure you have enough. It is always important to have extras of basic equipment, including the following:

- Personal protective equipment—disposable gowns, masks, goggles, and shoe covers
- Gloves, including latex-free gloves
- Biohazard bags and containers of various sizes
- Disposable underpads—can be used to provide a clean field for supplies; also used on the floor to place the home health bag
- Antibacterial soap
- Sanitizing liquid
- Disinfecting spray to clean equipment and bag after each visit
- Alcohol wipes for disinfecting thermometers and stethoscopes
- A small chemical spill kit

An important infection control measure is hand hygiene. It is important to wash your hands with soap and water before and after completing your patient care. If water is not available, use sanitizing liquid. Do not wash your hands in the patient’s kitchen sink; always ask to use the bathroom for washing your hands.

Documentation

Because of reimbursement guidelines, the nurse needs to document specific things during the visit. Home health agencies receive their income based on a prospective payment system (pre-determined rate), not per-visit payments. On admission, the RN fills out information that is entered into a computer system. This information is called the Outcome and Assessment Information Set, or OASIS-C. This tool is used to generate information about the home health agency and patient outcomes.
It is also used to help develop a plan of care that best meets the patient’s problems. The LPN/LVN should be familiar with the general function of this form and its relevance to creating a plan of care.

For home health agencies to be reimbursed, they need to demonstrate that a skill was completed. Documenting information is based on the patient’s plan of care and the corresponding skill that was completed at the visit. For example, the HCP orders skilled nursing observation and medication management for a patient. In documenting the visit for this order, the nurse needs to state that this skill was completed. Documentation would include the following:

- Patient’s response to medication—vital signs, level of consciousness, or other potential side effects
- Patient’s current understanding of medication regimen and the action the nurse took to improve that understanding
- Patient’s response to that education and any areas in which the patient might continue to need assistance.

Home health agencies, like hospitals, have different ways of documenting. The following items are typically included in all agencies’ home health documentation:

- Nurse’s arrival and departure times
- Assessment findings
- Vital signs
- A narrative note
- Patient’s signature verifying that the nurse was present in the home.

The documentation flow sheet is returned to the agency within an identified time frame (usually within 24 hours of a visit). Some agencies have secure drop boxes in which to leave paperwork after hours. When placing paperwork in the drop box, forms need to be neatly organized and attached together.

A folder with information is also kept at the patient’s residence. It usually consists of relevant patient information and a communication form that all staff members complete at each visit. Similar to hospital charting, this documentation is important to ensure continuity of care. It is even more vital in the home setting because staff members might not cross paths for a verbal report.

**EBP and Documentation**

OASIS-C, updated in 2012, is an assessment form that is completed by the RN during the first initial visit. Questions are related to identifying if problems exist beyond the referral diagnosis. It allows the RN to implement a plan of care that is evidence based, helping to eliminate potential complications and improve outcomes. These quality measures address the timeliness of care, care implementation, education, and prevention interventions. Indicators that can be flagged for further investigation by the RN include but are not limited to immunizations, falls, depression, pain, diabetic foot care, and heart failure. Additional information can be found at www.cms.gov.

The Agency for Healthcare Research and Quality is another resource to help guide the nurse in providing current care. A visit to www.qualitymeasures.ahrq.gov can offer information on disease specific care from the acute setting to home care. Follow links for “Measures”—“Disease and Conditions” (2013).

**Patient Education**

A primary responsibility of nurses in home health is educating patients about their illness and ways to effectively manage that illness at home with the intention of decreasing the need for hospitalization. Most home health agencies have handouts to help reinforce the verbal instructions the nurse provides. Many handouts are available from other sources as well, if needed.

**Learning Tip**

An easy way to make sure you always have the handouts you need is to organize them into a three-ring binder. Always have plenty of these handouts when making a visit. Many times, family members who do not live with the patient request copies so that they can have them at home. You can organize the information in several ways—for example, based on the diagnosis or alphabetically.

**Nursing Process for the Home Health Patient**

**Data Collection**

Monitor and document patient and family adjustment to change and illness. Perform a complete patient assessment during each visit. Assess the home environment for potential safety hazards and the need for devices to assist with care.

**Nursing Diagnoses, Planning, and Implementation**

Ineffective Self Health Management related to deficient knowledge, complexity of medical needs, and limited access to social support

**Expected Outcome**

- The patient will demonstrate changes in lifestyle needed to maintain health.
- Work with patient in developing both short- and long-term goals to ensure patient’s goals are being met.
- Recognize small accomplishments positively to reinforce patient’s progress.
• Educate patient on management of the health care regimen to allow patient to carry out regimen.
• Provide educational material in both written and verbal format to promote understanding of complex issues.
• Review plan of care with patient to facilitate involvement and eventual independence.
• Identify and work with social support systems to meet patient’s needs.
• Help patient obtain needed supplies to promote wellness.
• Assess the home environment for hazards and assist patient with making needed changes to promote safety.
• Assess the patient for changes in health status to detect changes that can affect progress.

Risk for Caregiver Role Strain related to management of a chronic illness and lack of understanding of resources available

Expected Outcome: The caregiver will identify effective ways for dealing with the complexity of a chronic illness.

• Include caregiver in the plan of care to help develop an understanding of the management of the illness.
• Assist caregiver with identifying community resources available such as respite care, Meals on Wheels, and support groups to meet patient’s needs.
• Enlist the help of a social worker to facilitate contact with community resources.
• Assess caregiver’s expectations of the patient’s health. Misconceptions regarding progress can foster anger and frustration toward the patient.
• Discuss ways to help caregiver deal effectively with feelings of anger and frustration to allow dealing with the feelings and issues causing them.
• Acknowledge the change in roles (e.g., a child taking care of a parent) and the challenges associated with this change in family roles to allow planning for the changes.

Evaluation
The patient and caregiver will acknowledge acceptance and understanding of the change in health status. This is evidenced by involvement in the plan of care and participation with goal setting, use of community resources, maintenance of a safe home environment, and demonstration of ability to manage medical regimen.

OTHER FORMS OF HOME HEALTH NURSING

Telenursing
Technology makes it possible to provide care in the home to patients in remote or rural areas, or after office hours. Telenursing, a branch of telehealth, uses information technology and telecommunication to provide nursing care. Various types of technology can be used including telephone, fax, e-mail, and video/audio conferencing. When it is time for the nurse to visit a patient located a great distance away, the nurse connects with the patient via equipment set up in the patient’s home. Because the nurse can see the patient, physical assessments can be made, including wounds. The nurse can then plan care and provide education to the patient. This form of home health care will likely grow as the aging population increases.

So far, this chapter has focused on home health care that is covered under the Medicare and Medicaid systems. The purpose of this type of home health is to assist the patient with managing health needs on an intermittent basis. Other types of home agency service work are also available for nurses, including private-duty nursing and hospice nursing (see Chapter 17).

Private Duty Nursing
Private-duty nursing consists of scheduled care to assist patients with personal and homemaking needs. These services have been called home companion services, homemakers, and private-duty care. Many of these services focus more on companionship and respite care. Families who are taking care of a patient with complex needs, such as a patient with Alzheimer’s disease, may need time away from the home to complete personal tasks. Agencies can provide both licensed and unlicensed assistive personnel (UAP) to help the patient while the family is away. These services are considered an out-of-pocket expense and are not covered by Medicare and Medicaid.

Families can contract with an agency to have a staff member spend 2 to 3 hours a day in the home. The staff can complete homemaking tasks and companion tasks, such as arts and crafts or playing cards. Nurses can work in these agencies in the role of supervisor to UAP. Nurses also may be involved in helping patients fill weekly medication dispensers. Many nurses enjoy this type of work because of the relationships that are formed with patients and families. They may be involved with the same family for months to years, as opposed to a few months, as is typical with Medicare home health patients.

SUMMARY
Home health nursing is a rewarding career path. Nurses who work in the home have the unique opportunity to assist patients during times of crisis and to experience the results of their interventions. Home health nursing will continue to grow in the 21st century, and the need for qualified professionals will offer many opportunities for the LPN/LVN. Thinking back on the impact that nurses such as Lillian Wald had and her ability to change the lives of so many because of her willingness to meet those patients in their homes, one can see the importance that home health nurses have in the successful progression for patients from illness to health and wellness.
CRITICAL THINKING

Mr. Rosa

1. The loss of Mr. Rosa’s wife and his subsequent health problems have affected his ability to properly care for himself. A nutritional diet is important for healing and maintenance of health. A referral to Meals on Wheels would be appropriate. This agency will deliver at least one healthy meal each weekday (usually lunch). The meal can be adapted to meet the patient’s dietary guidelines.

Many communities offer elder services to patients at a reduced cost to assist with housekeeping services. Helping the patient set up homemaker services will help him through this difficult time. Offering the patient information about grief counseling services in the community can be beneficial during this time. Once discharged from home health, the patient can begin attending counseling services. Other community resources to consider are neighborhood socials, church services if appropriate, and online communities that match the patient’s values.

2. The HCP needs to be contacted about the patient’s withdrawn demeanor and lack of interest in self-care. Mr. Rosa may be experiencing a situational depression because of the recent loss of his wife and his own health problems. During this time, the HCP might decide to prescribe an antidepressant to help.

3. The nurse recognizes that Mr. Rosa needs extra help at this time. Consider a referral for social services to assist with community resources and grief counseling. Because heart failure is a chronic disease that can contribute to fatigue, an occupational therapist can work with the patient in developing energy-conserving techniques for completing activities of daily living. Also the services of a home health aide can help with personal care and provide additional emotional support.

Mrs. Ambani

1. Because anemia can cause extreme fatigue, it is important for Mrs. Ambani to have safety devices in the home to prevent falls. These devices can be obtained from a medical supply store and are usually covered by Medicare. Equipment to consider includes a bath stool for the shower so the patient can sit while bathing, a detachable shower head, handrails in the shower and hallways, a bedside commode, an over-the-toilet seat, a reacher to assist with obtaining objects at a distance, a medical alert device that can be worn at all times, and, if fatigue is severe enough, a motorized wheelchair.

2. The home has many hazards. Important things to assess for include scatter/throw rugs, overcrowded spaces, sharp edges along furniture, inadequate lighting, and stairs. Instruct the patient to keep frequently used kitchen appliances and foods on shelves that are easy to reach. The same is true for the bathroom and bedroom. Assist the patient with setting up a “command center” in the living room so that favorite items are kept in proximity and the patient does not have to get up so frequently.

3. Links include checklist on assisting with fall prevention in relation to vision loss, medication safety, and general fall preventions. These checklists can be left in the home. Assessment forms that the nurse can use offer topics on orthostatic protocols and environmental safety.

REVIEW QUESTIONS

1. What impact did Lillian Wald have on the nursing profession?
   1. Allowed nurses to function as medical care providers.
   2. Demonstrated the impact nursing can have on patients’ health and wellness.
   3. Made it possible for nurses to obtain prescription drugs for patients in the home.
   4. Developed the Henry Street Settlement in 1890.

2. Which of the following are members of the home health team? Select all that apply.
   1. LPN/LVN
   2. Health care provider
   3. Social worker
   4. Home health aide
   5. Lawyer
   6. Patient
3. A patient is being seen by home health nurses for monitoring of weight and vital signs and education about medication changes following an acute exacerbation of heart failure. The nurse must document which of the following?
1. What the patient ate for breakfast
2. Distance the patient was able to ambulate while working with physical therapy
3. Education about the role of the home health aide in assisting the patient with personal care
4. Education about how to keep a log of daily weights and when to contact the HCP about a potential problem

4. An LPN/LVN has started working for a local home health agency and is concerned about the transition to home health nursing after working in the hospital for 10 years. What are some recommendations that would ease this transition for the LPN/LVN?
1. Explain that home health nursing is just like hospital nursing.
2. Instruct the nurse to always be prepared, to keep paperwork organized, and spend some time the night before a visit to review patient health information to help gain confidence in the home.
3. Allow an opportunity for exploring feelings and acknowledging that this is a hard transition.
4. Let the nurse know it is not possible to completely adjust to home health nursing because of variability in the home.

5. What steps can the home health nurse take to ensure that a patient is not exposed to infectious materials in the home?
1. Disinfect the home health bag after each patient visit with a germicidal spray supplied by the home health agency.
2. Perform hand hygiene in the kitchen sink rather than the bathroom sink.
3. Use the same red bag from patient to patient for disposing of soiled dressings.
4. If a chemical spill occurs, contact the agency to send personnel to clean it up.

Answers can be found in Appendix C.

Nursing Care of Patients at the End of Life

BETSY MURPHY

LEARNING OUTCOMES

1. Identify characteristics of the patient who is approaching the end of life.
2. List necessary legal documents for patients with life-limiting illness.
3. Explain choices that are available to patients at the end of life.
4. Demonstrate appropriate communication with dying patients and their families.
5. Describe physical changes to expect during the dying process.
6. Plan nursing interventions for patients at the end of life.
7. Describe postmortem care.
8. Plan nursing interventions for the grieving patient and family.
9. Discuss the role of the LPN/LVN in hospice care.

KEY TERMS

- advance medical directive (ad-VANSE MED-ih-kuhl dur-EK-tiv)
- advocate (ADD-vuh-ket)
- artificial feeding (ART-ih-FISH-uhl FEE-ding)
- artificial hydration (ART-ih-FISH-uhl hy-DRAY-shun)
- do not resuscitate (DNR) (DOO not re-SUSS-ih-TATE)
- durable power of attorney (DUR-uh-buhl POW-ur OV uh-TUR-nee)
- hospice (HOS-pis)
- living will (LIH-ving WIL)
- palliative (PAH-lee-uh-tiv)
- postmortem care (pohst-MOR-tum KARE)
Mr. Moran, 89 years old, resides in a long-term care facility and has been losing weight and growing weaker for the past 6 months. Despite treatment for depression, he continues to grow weaker and more dependent on his caregivers. As you read this chapter, consider what decisions his family will face and what resources are available to them in their quest to provide appropriate care for him.

### A GOOD DEATH

Despite our best efforts, there will come a time when all our patients will die. Death is the expected end to a life well lived. In America, only 10% of us will die suddenly. The remaining 90% will experience a gradual decline over a period of months or years.

In the 21st century, most Americans will die from chronic and acute illnesses such as cancer, heart disease, stroke, and dementia. We have the technology to prolong life, but sometimes this longer life can carry with it profound disability and reduced quality of life. Our patients sometimes tell us that this is not what they intended for the last phase of their life. So what is the role of the nurse with patients nearing the end of life? Two priorities are (1) to help identify patients with life-limiting illnesses early so that they and their families have the opportunity to redefine their goals of care and (2) to help our patients communicate their wishes to health care providers (HCPs), both orally and in writing, to ensure that their wishes are understood.

Perhaps the most important role for nurses is to give our patients support and validation as they move through the series of losses leading to a good death. Dying is, after all, the final phase of our growth and development. The developmental tasks associated with this phase involve reflecting on our lives, saying goodbye, saying, “I’m sorry,” and saying, “I love you.” The goal of having a “good death” is a valid goal.

There have been multiple studies focused on identifying the needs of terminally ill patients and their families (Gardner & Kramer, 2010). The findings fit into five categories:

- **Adequate pain and symptom management**
- **Ability to make their own decisions**
- **Avoidance of unnecessary life-sustaining treatment and prolongation of the dying process**
- **Reducing the emotional and financial burden on their families**
- **Ability to use remaining time to strengthen relationships with loved ones**

This description of a good death helps nurses listen to what patients want and to focus on how best to help them achieve their goals. Nurses who choose to provide care for the dying will experience personal growth in their own lives. Facing the inevitability of our own mortality can force us to look more deeply at our beliefs, values, and priorities in life. This can result in a richer, more focused life.

### IDENTIFYING IMPENDING DEATH

Most Americans say that they want to die at home. Home for many patients will mean the place they are most comfortable, surrounded by caregivers who understand their needs and provide attentive care. Home can be where they live independently or with their families. It can also be in a continuing care retirement community, assisted living facility, or nursing home. In the United States, 30% to 40% of older adults die in long-term care facilities. A surprising 80% of older patients die within a year of admission to a nursing home (Kelly et al, 2010). Nurses who are working in long-term care and assisted living facilities will find themselves in a position both to identify patients who are likely to die soon and also to support these patients’ families in planning for a good death. Because so many patients die within months of admission to long-term care, identification of their wishes should be done soon after admission. If a frail older patient’s wishes are not documented and the person becomes ill, he or she will be routinely transported to the hospital, possibly to receive unnecessary treatments.

How can you identify patients who are nearing the end of their lives? Some patients die because of disease, but some patients simply show weight loss and progressive weakness as signs that they are in the final months of life. Research has shown that measuring both weight loss and increasing dependency in activities of daily living (ADLs) can help to identify patients who are dying. Weight loss is a useful marker of mortality risk in older adults (Alley et al, 2010). Weight loss caused by depression or acute illness can sometimes be reversed with aggressive treatment. But if neither depression nor acute illness is the cause of the patient’s decline, he or she may be entering the final months of life. Worsening symptoms may also be an indicator of decline. One study shows that 25% of older men had pain in their final 2 years of life, and 50% to 60% of men had pain in the final months of life (Smith et al, 2010).

Older patients who are having trouble swallowing and require treatment for aspiration pneumonia are likely to die within a year. Their decreased respiratory muscle strength, lack of lung elasticity, and poor immune response make recovery unlikely. Older patients with poor renal and cardiac functions are also at high risk for dying. The final truth is that for some older patients with chronic illness, many treatments offer little benefit.

For most patients, the transition from treating an illness to allowing the patient to die is a gradual process. Figure 17.1 shows the evolving relationship between treatments intended to cure and treatments intended to comfort as the patient approaches the end of life. As curative therapies are reduced, comfort care, or palliative measures, are increased. This chapter explores some of the choices people need to make at the end of life and the interventions you can use to help patients during this time.
ADVANCE DIRECTIVES, LIVING WILLS, AND DURABLE MEDICAL POWER OF ATTORNEY

The Patient Self-Determination Act, which took effect in 1991, ensures that every patient has the right to accept or refuse any medical treatment that is offered. The act also requires HCPs to ask patients entering a hospital if they have prepared advance medical directives. These include a living will and a durable power of attorney for health care. In preparing advance medical directives, patients are exercising their right to make their wishes known regarding specific medical treatments they would want—or not want—if they become unable to make decisions on their own. The directives require the signatures of two witnesses; neither can be a family member or HCP.

A living will is a document instructing HCPs about a patient’s preferences (such as to withhold or withdraw life-sustaining procedures) if the patient is unable to communicate, found to be permanently unconscious, and/or has been declared “terminal.” A durable power of attorney for health care specifies who will speak for a patient when he or she cannot speak. Many states provide standard forms to use and may require the patient to have both a durable power of attorney for health care and a living will to ensure the patient’s wishes are followed. An attorney, although not required, may be helpful for some families.

Encourage patients not only to fill out the necessary forms but also to discuss their wishes with all family members. It is estimated that only about 20% to 30% of Americans have advance medical directives. Some patients are reluctant to complete them, concerned that they may change their minds about treatments in the future. It can be helpful to talk about advance care planning as a process. Patients can change their minds at any time about any treatment and write new advance directives. What matters most is that they get started and document their wishes today.

Do Not Resuscitate Orders

A “No Code” or DNR order is written in a hospital or long-term care facility after collaboration with the patient, family, and the HCP, usually after it has been determined that the patient will not benefit from CPR. A DNR order simply means that CPR will not be done. Patients must still decide whether they want aggressive treatment of their underlying condition, up to but not including CPR, or whether they want only comfort measures without therapeutic treatment. Some hospitals offer several options:

• DNR/Comfort Care Only
• DNR/Full Therapeutic Support
• Full Code

Outside the hospital, at home, or in most nursing facilities, patients will have fewer options for aggressive treatment. Patients can, however, choose to have a DNR order that will be recognized by emergency personnel. Many states have a Durable DNR document that, once signed, can be displayed in the patient’s home to advise rescue personnel that the patient does not want CPR. These may also be called out-of-hospital or prehospital DNR orders.

Many people assume that their documented desire not to receive resuscitation in a living will is all that is needed. This is not correct. In states that have an out-of-hospital DNR policy, patients must also complete the durable DNR document or they will receive CPR regardless of their stated wishes. There is also a new document for patients with life-limiting illness called Physician Orders for Life Sustaining Treatments (POLST). This document is signed by both the patient or the patient’s decision maker and the patient’s physician. This is a physician’s order for emergency medical services (EMS) to follow. The order can specify whether the patient wants CPR and list the patient’s choice of treatments. EMS workers are trained to look for such a document, often in a bright color and hanging on the patient’s refrigerator.

Some patients fear that in choosing DNR status, they will suffer and be alone at the time of their death. Patients and families may erroneously perceive DNR as withholding a treatment that could benefit the patient. It is important to tell patients that DNR does not mean do not treat. Patients who have a DNR/Comfort Care Only order will still receive oxygen, medications, and other comfort measures to aggressively manage their symptoms and ensure a comfortable death. A gentler way of discussing this choice may be to ask patients and families if they prefer to allow natural death. All DNR orders and discussions with families should be documented on the patient’s chart (see “Patient Perspective—Anna”).

Artificial Feeding and Hydration

Patients may be unable to eat or drink as a result of three conditions: an acute illness, a long illness with multiple medical problems, or simply the aging process. Otherwise, healthy patients who are unable to eat while recovering from an acute illness will probably benefit from artificial feeding. An example of this would be a cancer patient receiving total parenteral nutrition (TPN; see Chapter 7) or tube feeding to prevent weight loss.

Patient Perspective

Anna

My mom, Anna, was diagnosed with cardiomyopathy and congestive heart failure when she was 60 years old. At that time, she was still working and had just remarried. She thought she had many years left in life. She did not have an advance directive—why would she?

Two years later, as her disease progressed, she decided she did not ever want to “live on machines.” So with the help of her doctor and our family, she wrote her living will and made her new husband her durable power of attorney for health care, with me as his backup person. Because she was still functioning really well with lots of medications and occasional hospitalizations, she chose a DNR status, but with full therapeutic, aggressive interventions. She even took a tour of Europe during this time in her life, knowing she would not be able to do it later.

By age 67, she had a lot less energy to do things, and her heart failure really cramped her lifestyle. But she still enjoyed life, and her goal was to see her oldest grandson, my son, graduate from high school. She considered a heart transplant, but her doctor told her she was too old to qualify. She did have a new kind of valve surgery that was supposed to make her feel better, but it didn’t help much.

Three months after my son’s graduation, she was hospitalized several times with progressively worse outcomes. She weighed barely 100 pounds and could not eat much. She was only 70 years old, and still looked and acted so young! Finally, she was in a semi-coma in the hospital, and our family had to make the difficult decision to withdraw all therapeutic support. She was now a DNR, with comfort measures only. We were confident this would be what she wanted because we had talked about it with her. She was alert enough to let us know that she wanted to die at home.

She was discharged home with hospice care and died within a week. I moved in for her final days to help out, and between her husband and me, her hospice nurse (who was a godsend), and frequent visits from family and her minister, she was well cared for. We kept her comfortable with lots of attention and morphine. She was alert and able to converse much of the time. She ate what and when she wanted, which amounted to one-quarter of a cheese and tomato sandwich one day, but she enjoyed it! She could finally enjoy a glass of grapefruit juice, which she had been unable to have for years because it interacted with one of her heart medications.

At the end, she died with me holding her left hand and her husband holding her right. We were telling her we loved her. It was a good death.
CRITICAL THINKING

Mrs. Hart

Mrs. Hart has written a living will specifying her wishes should she become incapacitated. Because she has advanced disease, she tells you she would not want to be resuscitated if she has a cardiac arrest. She is currently hospitalized but will be discharged to her home in a few days.

1. What documents does she need to have in place to ensure she will not receive resuscitation?
2. What health team members should you collaborate with in helping Mrs. Hart through this process?

Suggested answers are at the end of the chapter.

loss while receiving a treatment such as chemotherapy or radiation that is known to cause weight loss. In contrast, patients who are losing weight because of a life-limiting illness with multiple medical problems or the aging process itself will probably not benefit from artificial feeding. Research has shown that “no strong evidence exists supporting the use of parenteral hydration/nutrition for the majority of terminally ill patients” (Day, Dalal, & Bruera, 2012). “Terminally ill patients” includes not just patients declining from advanced cancer but also patients with life-limiting diseases such as Alzheimer’s dementia, Parkinson’s disease, and other conditions.

It is now widely accepted that feeding advanced dementia patients via feeding tube does not prolong their life or enhance their quality of life. Despite this fact, many patients continue to receive feeding tubes because their families are not consistently provided with evidence-based information to make good decisions (Teno et al, 2011). Providing families with this evidence-based information as part of advance care planning can help families to make the best possible decisions for their loved ones. The Alzheimer’s Association provides educational information for families of patients with dementia. It recommends that instead of a feeding tube, these patients receive an effective program of hand feeding (www.alz.org).

When a patient is recognized as having entered the dying phase, medical treatment should contribute to comfort. Research suggests the benefits of artificial nutrition and hydration may be limited and may not outweigh the burdens (Raijmakers et al, 2011). There are some benefits to withholding artificial feeding and artificial hydration in the final weeks of life in all actively dying patients. These benefits are:

- Fewer pharyngeal and lung secretions, which can reduce dyspnea
- Reduced swelling around tumors, which can reduce associated pain
- Less urination, resulting in dryer skin with less skin breakdown

It has been theorized that as dehydration occurs, the body produces a form of endorphin that enhances comfort. As ketone levels rise from the breakdown of body fat, patients experience an anesthetic effect that creates a sense of well-being. Families often express concern that the patient will experience hunger or thirst. Hospice providers report observational evidence that dying patients do not report hunger or do report having a dry mouth. Mouth dryness can be easily managed with good mouth care.

The issue of feeding is emotionally difficult for families. Often their loved one has been ill a long time. Bringing favorite foods may have been one of the ways they showed love and communicated caring. Families will need support in making decisions about feeding in three important ways:

- Identifying goals of care and evaluating whether artificial feeding will help meet those goals
- Weighing the benefits and burdens of feeding
- Finding new ways (besides feeding) to communicate their love, such as skin care, mouth care, or reading to their loved one

For a different perspective on artificial feeding, see “Ethical Considerations” for Chapter 17 at davispl.us/medsurg5.

Hospitalization

A hospital is where patients go to receive aggressive medical treatment. The goal of care in a hospital is to improve the patient medically and transfer him or her to an appropriate level of care that will better meet individualized needs. There are burdens associated with hospitalization for older adult patients approaching the end of life. They may actually decline more rapidly in a hospital setting. When removed from a setting with predictable routines and known caregivers, the older patient often eats less and becomes at risk for weight loss. Research has shown that all older adult patients suffer accelerated cognitive decline after hospitalization (Wilson et al, 2012). They enter a foreign environment and are cared for by health care workers who do not know them. Patients may be physically restrained as they become agitated and fearful while away from home. Patients who are frail and have poor immunity are at risk for developing infections. They often enter the hospital with one infection and are discharged with other infections that may be resistant to antibiotics or caused by antiotics, such as *Clostridium difficile*. There is evidence that receiving antibiotic therapy for infection may prolong survival in some patients with advanced dementia, but patients who received antibiotics had more discomfort than those who received no antibiotics (Gi vens, Jones, Shaffer, Kiely, & Mitchell, 2009). Helping families decide on goals for the patient’s care will help with making decisions in the future. If the patient or family decides on comfort care only, then going to the hospital or receiving antibiotics may not meet their goal.

Patients living in nursing facilities with end-stage dementia who have severe cognitive impairment will benefit from having a “do not hospitalize” order. This will maintain the patient in an environment that feels safe and preserves his or her chosen quality of life. Having hospice care in place (see next section) in nursing facilities can help reduce hospitalizations (Dobbs, Meng, Hyer, & Volicer, 2012).
Hospice Care

Many people think of hospice as a place. It is actually a service. The service is provided in private homes or independent and assisted living facilities. It can also be provided in hospitals and nursing homes when there is a signed contract between the hospice organization and the facility. To qualify for hospice care, a patient must have an estimated prognosis of 6 months or less. Patients can receive hospice care longer than 6 months as long as their health continues to decline.

Some indicators of a 6-month or less prognosis (regardless of diagnosis) are 10% loss of weight in 6 months, functional decline, frequent hospital admissions, and recurrent infections. The goal of hospice care is holistic: to manage symptoms such as pain and nausea, to provide emotional and spiritual counseling for the patient and family, and to support the patient in achieving his or her goals of care. Each patient is assigned a multidisciplinary hospice team (Table 17.2) to assist with care.

Most health insurance companies now provide a hospice benefit. Many are modeled after the Medicare hospice benefit. The Medicare benefit pays for both routine hospice care at home and for inpatient hospice care provided in a contracted hospital, skilled nursing facility, or freestanding hospice unit. Medications, medical supplies, oxygen, and medical equipment are also covered if they are related to the terminal diagnosis.

Hospice care can help a family take care of a patient at home, but hospice nurses do not routinely provide 24-hour in-home care. (A nurse is on call for in-home visits 24 hours a day.) Nurses and other team members make regular visits to support the patient and family. In times of medical crisis, short-term inpatient hospice services or 24-hour in-home continuous nursing care may be provided under some hospice benefits.

---

**TABLE 17.2 THE HOSPICE TEAM**

<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physician or other HCP</td>
<td>Works with the patient’s primary HCP, offering suggestions to improve care. Directs team activities and often will make visits to the patient’s home.</td>
</tr>
<tr>
<td>Nurse</td>
<td>Makes routine home visits, assessing patient needs and implementing plan of care. Nurses are available 24 hours per day to make visits as needed.</td>
</tr>
<tr>
<td>Social worker</td>
<td>Provides emotional counseling and long-term planning, assists patients with insurance issues, and helps identify community resources.</td>
</tr>
<tr>
<td>Chaplain or minister</td>
<td>Provides spiritual counseling or coordinates care of spiritual issues with the patient’s chosen spiritual counselor. May participate in funeral or memorial service.</td>
</tr>
<tr>
<td>Home health aide</td>
<td>Provides personal care, linen changes, light housekeeping.</td>
</tr>
<tr>
<td>Volunteers</td>
<td>Support caregivers by staying with the patient while they get out of the house. May also read to patient, run errands, etc.</td>
</tr>
<tr>
<td>Bereavement counselor</td>
<td>Provides counseling for family and significant others for 13 months after patient’s death.</td>

---

**COMMUNICATING WITH PATIENTS AND THEIR LOVED ONES**

Terminal illness is a family experience. Family is defined by the patient and may include blood relatives, friends, significant others, or partners. The primary role of the nurse is to facilitate a comfortable death that honors the choices of the patient and family. The nurse, therefore, becomes the advocate, assuring that patient and family wishes are communicated to other members of the health care team. In addition, the nurse is often the professional caregiver and educator of the nonprofessional caregivers and family.

To successfully work with dying patients and families, you must demonstrate empathy, unconditional positive regard, trustworthiness, and critical thinking. You are part of an interdisciplinary team. The team consists of the HCP, nurse, social worker, chaplain, and others. Each discipline has expertise and can lend support to the others in providing care. As illustrated in the earlier section on end-of-life choices, patients and their loved ones need support and evidence-based information to make good decisions. All members of the team can assist with this support.

Good communication requires that you take time to listen, answer questions honestly, help identify choices, and allow verbalization of fears. Eighty percent of communication is nonverbal, such as eye contact, body language, and tone of voice. Take time to identify your own communication barriers that will affect your ability to talk with families. Do you have fears about your own mortality or lack personal experience with death? Do you fear being blamed for decisions, or disagree with decisions that were made? These barriers will affect your ability to sit with patients and families in crisis, sustain eye contact, and support them in their process. Practice attentive listening with patients and families. Allow them to talk. Be silent, don’t change the
subject, and know that you do not need to have all the answers. Your role can be to help them reflect on what they are trying to communicate and to clarify their goals of care so you can better advocate for them.

Set the stage for communication by sitting down to show you are not in a hurry (Fig. 17.2). Maintain eye contact, encourage patients to speak, repeat what they say to gain clarification, and reflect on its meaning. Some things to say to facilitate good communication include the following:

- “Do you feel like talking?”
- “Tell me more about your fears of . . . .”
- Repeat back what you hear: “You mentioned you were upset by . . . .”
- Reflect: “So are you saying that . . . ?”
- “What does this mean to you?”
- “How can I help you?”

From the patient’s perspective, many factors influence the content and quality of communication with you. Some patients are so afraid that they cannot hear what they have been told about their illness. It can be helpful to ask what the doctor has said to get baseline information about where they are in understanding their disease.

Patients may use denial as a mechanism to protect themselves from becoming overwhelmed by emotion. The denial is necessary to enable them to survive on a day-by-day basis. You do not need to correct their denial. Some patients remain in denial throughout the course of their illness. When patients in denial ask you a direct question about their condition, it can be an indicator that they are ready to hear the truth. It is essential that you always answer questions honestly and to the best of your knowledge. Dishonesty destroys trust and credibility.

Patients and their families may also feel angry. Allowing them to express their anger will validate it and enable them to progress emotionally. Comments such as “It is okay to be angry with God and anybody else” will encourage them to continue to talk. Patients who fully understand their prognosis will express sadness and regret. Sitting with patients as they express sadness will allow them to share their feelings and give you an opportunity to offer emotional support.

### THE DYING PROCESS

This section discusses the expected changes in the days and hours before death. Assessing patients for these changes, planning and implementing treatments, and evaluating patients’ responses to interventions are all important. Nursing interventions are summarized in the “Nursing Care Plan for the Patient at the End of Life.”

(Text continued on page 316)
### NURSING CARE PLAN for the Patient at the End of Life—cont’d

**Intervention** Explain to the family the rationale for medical interventions. **Rationale** Blood transfusions may be given to improve oxygenation and reduce dyspnea; a thoracentesis may promote lung expansion. These are not intended to prolong life but to promote comfort. **Evaluation** Are additional interventions needed and effective? Does family understand rationale for their use?

**Intervention** Plan activities to conserve energy. **Rationale** Spacing rest with activity will help reduce oxygen consumption. **Evaluation** Can patient tolerate spaced activities?

**Intervention** Place patient in a recliner with pillows to 45 degrees. **Rationale** An upright position allows lung expansion. **Evaluation** Does positioning reduce dyspnea?

**Intervention** Offer alternative comfort measures, such as massage and muscle relaxation. **Rationale** Relaxation reduces anxiety and resulting dyspnea. **Evaluation** Are alternative measures effective?

**Intervention** Administer oxygen as ordered. **Rationale** Oxygenation raises SpO₂ and reduces dyspnea. **Evaluation** Does oxygen raise SpO₂ and relieve dyspnea?

**Intervention** Place a fan in room if patient desires. **Rationale** The feeling of breeze may reduce subjective feelings of dyspnea. **Evaluation** Does patient report increased comfort or appear more comfortable with fan on?

**Intervention** Administer low-dose morphine as ordered. **Rationale** Morphine causes peripheral vasodilation, which can reduce pulmonary edema. It can also reduce anxiety. **Evaluation** Are respirations less labored after morphine?

**Intervention** Explain to patient and family that small dose of morphine will help to slow breathing, so patient feels more comfortable and will work on the part of the brain that makes patient feel short of breath, reducing the sense of panic. **Rationale** The informed patient and family will be able to cooperate and assist with keeping the patient comfortable. **Evaluation** Do patient and family understand reasons for care and feel secure that patient is receiving best possible care?

**Nursing Diagnosis:** *Ineffective Airway Clearance* related to excessive secretions and inability to swallow as evidenced by gurgling sound, “death rattle”

**Expected Outcome:** The patient’s airway will be free of secretions.

**Evaluation of Outcome:** Is patient’s breathing quiet and unlabored?

**Intervention** Adjust the patient’s head to allow secretions to move down the throat. **Rationale** This will help the patient swallow the secretions and decrease frightening noise. **Evaluation** Is breathing quieter?

**Intervention** Place a humidifier in the room. **Rationale** Humidified air can liquefy secretions and help the patient cough. **Evaluation** Is patient able to cough up secretions?

**Intervention** If secretions are copious, administer hyoscyamine or scopolamine as ordered. **Rationale** These anticholinergic medications can dry secretions. **Evaluation** Do medications help dry secretions?

**Intervention** Administer low-dose morphine as ordered. **Rationale** Morphine has an anticholinergic action that can help dry secretions. **Evaluation** Does morphine help quiet breathing and help patient stay calm?

**Intervention** Suction patient as needed. **Rationale** If secretions are not controlled by noninvasive measures, suctioning may be needed. **Evaluation** Is suctioning needed? Is it effective?

**Intervention** Explain to patient and family that, “Because he can no longer swallow saliva, it collects in the back of his throat. This medication will help reduce the secretions and reduce the feeling of shortness of breath.” **Rationale** The informed patient and family will be able to cooperate and assist with keeping the patient comfortable. **Evaluation** Do patient and family understand reasons for care and feel secure that patient is receiving best possible care?
**NURSING CARE PLAN for the Patient at the End of Life—cont’d**

**Nursing Diagnosis:**  *Imbalanced Nutrition: Less Than Body Requirements* related to inability to swallow and lack of appetite as evidenced by refusing food, weight loss.

**Expected Outcomes:** The patient will state satisfaction with amount and types of food offered. The patient will not aspirate food or fluid.

**Evaluation of Outcomes:** Does patient appear content with foods and fluids offered? Does he or she swallow without aspirating?

**Intervention** Let the patient choose when and what to eat. Do not force the patient to eat if he or she does not wish to.  
**Rationale** The goal is no longer providing adequate nutrition but keeping the patient comfortable.  
**Evaluation** Is the patient receiving the foods and fluids he wants?

**Intervention** Sit the patient upright to eat or drink.  
**Rationale** This can help the patient swallow and prevent aspiration.  
**Evaluation** Does patient swallow effectively?

**Intervention** Explain to family, as needed, that, “He is afraid to swallow now because his swallowing is impaired and it causes him to choke. As he becomes dehydrated, his comfort will increase as the body produces naturally occurring anesthesia.”  
**Rationale** The informed patient and family will be able to cooperate and assist with keeping the patient comfortable.  
**Evaluation** Do patient and family understand reasons for care and feel secure that the patient is receiving best possible care?

**Nursing Diagnosis:**  *Impaired Oral Mucous Membrane* related to dehydration, not eating, medication side effects.

**Expected Outcome:** The patient’s mucous membranes will be clean and moist.

**Evaluation of Outcome:** Are mucous membranes clean and moist? Does patient indicate that his mouth is moist?

**Intervention** If patient is alert, offer ice chips or sips of water.  
**Rationale** These keep mucous membranes moist.  
**Evaluation** Does patient indicate mouth feels comfortable?

**Intervention** Provide frequent mouth care with sponge-tipped Toothettes.  
**Rationale** This can keep mucous membranes moist when patient is not able to drink adequate fluids.  
**Evaluation** Is mouth clean and moist?

**Intervention** Apply lanolin to lips.  
**Rationale** Lanolin keeps mouth and lips from becoming dry and crusty.  
**Evaluation** Are lips smooth and moist?

**Nursing Diagnosis:**  *Impaired Comfort* (pain, terminal restlessness) related to disease process, dying process, medications.

**Expected Outcome:** The patient will state that he or she feels comfortable or, if unable to speak, will appear calm and peaceful, not restless or agitated.

**Evaluation of Outcome:** Is patient comfortable, calm, and peaceful?

**Intervention** Assess for reversible causes of agitation:  
• Pain or other discomfort  
• Urine retention or fecal impaction  
• Medications that are no longer beneficial  
• SpO₂ <90%.  
**Rationale** Often, agitation is a sign of discomfort. Identifying and removing the cause of the discomfort can help calm the patient.  
**Evaluation** Can causes be identified? Are they removed?
NURSING CARE PLAN for the Patient at the End of Life—cont’d

**Intervention** Reposition in bed at least every 2 hours and as needed. **Rationale** Repositioning frequently can promote comfort and relieve pressure on bony prominences. When other medical interventions are discontinued, the patient still needs to be repositioned regularly to prevent uncomfortable complications. **Evaluation** Does repositioning promote comfort?

**Intervention** If SpO₂ is low, administer oxygen as ordered. **Rationale** Low SpO₂ causes dyspnea, which is not comfortable. **Evaluation** Is SpO₂ raised to 90%? Is patient’s breathing unlabored?

**Intervention** Discuss with the HCP discontinuing all uncomfortable procedures, such as blood draws and finger-sticks for blood glucose. **Rationale** Many procedures provide information to the staff but are not beneficial to the patient at the end of life. They should be discontinued. **Evaluation** Are any uncomfortable procedures still being carried out that are not absolutely necessary?

**Intervention** If the cause of the agitation cannot be determined, try medication for pain, dyspnea, or anxiety as ordered. **Rationale** Medication may need to be administered based on objective observations if the patient is unable to communicate. **Evaluation** Does medication promote comfort?

**Intervention** Keep the patient safe with one-on-one monitoring and side rails up. **Rationale** A fall would increase the patient’s discomfort. **Evaluation** Is patient safety maintained?

**Intervention** Keep perineal area clean and dry, frequently checking adult briefs. **Rationale** A wet brief is not comfortable. Unchanged briefs can also lead to skin breakdown, another source of discomfort. **Evaluation** Is patient clean and dry with intact skin?

**Intervention** Teach the patient and family that “Restlessness can have many causes. It can be a sign of pain, bowel or bladder problems, or a medication issue. I will work with the HCP to improve the situation.” **Rationale** The informed patient and family will be able to cooperate and assist with keeping the patient comfortable. **Evaluation** Do patient and family understand reasons for care and feel secure that patient is receiving best possible care?

**Nursing Diagnosis:** Hypothermia or Hyperthermia related to dying central nervous system and inability to regulate body temperature

**Expected Outcomes:** The patient’s temperature will be maintained as close to normal as possible, and discomfort from temperature extremes will be managed.

**Evaluation of Outcomes:** Is temperature within normal limits? If unable to control temperature, does patient appear comfortable?

**Intervention** Administer acetaminophen suppository as ordered. **Rationale** Acetaminophen is an antipyretic. It is given by suppository if the patient cannot swallow. **Evaluation** Does acetaminophen reduce fever?

**Intervention** Keep the patient clean and dry. Change gown and bed linens as needed. **Rationale** A fever can cause diaphoresis (excessive sweating), and lying in damp sheets can be uncomfortable and cause skin breakdown. **Evaluation** Is patient kept dry and comfortable?

**Intervention** If the patient is cold, add blankets as needed. Do not use an electric blanket or heating pad. **Rationale** Blankets will warm the patient without risking burns from electric heating devices. **Evaluation** Are blankets helpful?

**Nursing Diagnosis:** Acute Confusion related to neurologic changes

**Expected Outcomes:** The family will voice understanding that confusion is not uncommon and will show appropriate responses if it occurs.

**Evaluation of Outcomes:** Does the family respond appropriately to patient during times of confusion?
NURSING CARE PLAN for the Patient at the End of Life—cont’d

**Intervention** Assure families that some confusion is common. **Rationale** If family is prepared, confusion will be less disturbing. **Evaluation** Is family informed? Do they verbalize understanding of what to expect?

**Intervention** Do not correct the patient but instead encourage the patient to talk about what is happening. **Rationale** Sometimes patients talk about their fears in metaphor. Allowing them to express this fear will promote relaxation and decrease loneliness. **Evaluation** Is the patient less distressed after speaking?

**Intervention** Keep a dim light on in the room, and remind the person gently of who is present. **Rationale** Being able to see clearly helps keep the patient oriented if he or she awakens during the night. **Evaluation** Is the light on? Is patient able to orient himself or herself on awakening?

**Intervention** Explain to family that “Many patients don’t make sense at times. It is as if they are in two worlds at the same time. The patient will be less distressed if you let him (or her) talk about what he (or she) is experiencing.” **Rationale** Family members will be less distressed if they understand what is happening. **Evaluation** Does the family respond appropriately to the patient’s confused statements?

**Nursing Diagnosis:** Fear related to threat of death

**Expected Outcome:** The patient will be treated as still present and respected, and not as though he is already gone.

**Evaluation of Outcome:** Is communication respectful toward the patient?

**Intervention** When providing care, always speak as if the patient can hear you. When conversing with family members in the room, remember that the patient also can hear what you are saying. **Rationale** Patients may be able to hear even when they appear to be nonresponsive. Always assume the patient can hear you. **Evaluation** Are caregivers and family members sensitive to the patient’s presence when communicating?

**Intervention** When giving care, explain softly to the patient what you are doing and why. **Rationale** Knowing what is happening can reduce anxiety and increase cooperation. **Evaluation** Does patient appear calm? Does he respond to your explanations?

**Intervention** Explain to family that “Hearing is the last sense to go. This can be a good time to say the things you have not been able to say. He (or she) may still hear you.” **Rationale** Continued communication can be comforting to both the patient and the family. **Evaluation** Is communication appropriate?

**Nursing Diagnosis:** Anticipatory Grieving related to impending death

**Expected Outcome:** The patient and family will be able to openly communicate their feelings to each other and say goodbye.

**Evaluation of Outcome:** Are patient and family able to communicate effectively and say goodbye to each other?

**Intervention** Be present with the patient. Just sit quietly and hold the patient’s hand for a period of time. **Rationale** This can help the patient feel less alone, especially if there are no family members present. Many patients fear dying alone. **Evaluation** Is someone present with the patient as much as possible?

**Intervention** Show appropriate concern. **Rationale** This will promote trust and empower the family members to ask for what they need. **Evaluation** Is the family communicating openly with the providers?
Educating family caregivers about what to expect is essential. Caregivers who anticipate the expected changes and understand the rationale behind the interventions are more successful in their caregiving and have fewer regrets or concerns after the death. The Nursing Care Plan includes specific communications that may help caregivers understand what is happening and how they can help.

**Eating and Drinking**

As our bodies move toward death, there is less desire for food and fluids. Patients are conserving energy and often do not feel hungry. The swallowing reflex can be impaired, increasing the risk of choking. Patients fear choking and may hold their mouth tightly closed when food or fluids are offered. This is normal, and the resulting dehydration will increase comfort due to endorphin production and rising ketone levels.

**Changes in Breathing**

About 50% to 70% of patients have dyspnea at the end of life. Patients who are alert may report dyspnea. Those who are not alert may have tachypnea (respiratory rate greater than 24 per minute), facial grimacing, and use of accessory muscles to breathe. Untreated dyspnea can lead to fear and agitation, leading to more dyspnea. Some patients also will have episodes of apnea in the days or hours before they die.

Dyspnea has many causes. Pneumonia, anemia, congestive heart failure, and pleural effusion can be successfully treated early in the course of illness. Dyspnea that occurs in the final hours of life is not treated by correcting the underlying condition but can be effectively managed and controlled (see the “Nursing Care Plan for the Patient at the End of Life” and “Evidence-Based Practice”).

**Oral Secretions**

Saliva that the patient is now unable to swallow may collect in the back of the throat, causing a sound sometimes called a death rattle. This can be disconcerting for the family. See the "Nursing Care Plan for the Patient at the End of Life" for interventions.

**Temperature Changes**

As the body loses its ability to control temperature, the patient may become diaphoretic or feel cold all the time. Some patients have experienced fevers as high as 105°F (40.5°C). As death approaches, the feet and legs may become cool, cyanotic, and mottled. This is often an indicator that death will occur within hours.

**Bowel and Bladder Changes**

Most patients will become incontinent of bowel and bladder during the course of the dying process. Urine output will decrease as dehydration occurs. Urine often will darken in color and have a strong odor.

**Sleeping**

In the final weeks of life, patients may be sleeping for most of the day. This is due to a change in metabolism. They also begin to emotionally detach from families as part of their preparation to leave.

---

**EVIDENCE-BASED PRACTICE**

Clinical Question

Are opioids (morphine) effective in controlling dyspnea? Do opioids compromise the respiratory system of patients with dyspnea?

Evidence

A review of randomized controlled trials of patients with chronic obstructive pulmonary disease (COPD) showed that opioids were effective in relieving dyspnea without major adverse effect (Varkey, 2010).
Mental Status Changes

As patients go through the process of dying, they often have episodes of confusion, possibly from electrolyte imbalance or medications. Some patients will say things like, “I have to catch a train” or “I need my passport.” This metaphorical communication is well documented in the hospice literature. It is almost like patients are living in two worlds (Callanan & Kelley, 1992).

Terminal Restlessness

Terminal restlessness is a syndrome observed in a significant number of patients with various diagnoses during the final days of life. The patient may be unable to concentrate or relax and may show nonpurposeful motor activities such as picking at the sheets. The patient may hallucinate or try to climb out of bed. Terminal restlessness can have many causes, including hypoxemia, metabolic abnormalities, and liver failure. Some physical causes may be reversible, so it is important to assess whether pain, urine retention, or fecal impaction may be the cause.

Restlessness may also be caused by medications. As kidney and liver functions decline, medication levels rise in the body and cause toxicity. Consult with the HCP and pharmacist to determine if all the medications the patient is receiving are beneficial or necessary. Table 17.3 reviews medications that may be helpful at the end of life.

Unconsciousness

Most patients are unconscious for hours or days before they die. Before they lose consciousness, their ability to see may

<table>

<tbody>
<tr>
<td>Opioids</td>
<td>morphine (MS, MS-IR, MS Contin, Roxanol) hydromorphone (Dilaudid) fentanyl (Sublimaze, Actiq, Fentora)</td>
<td>For pain and dyspnea. Must be given routinely to be effective. Give routinely. Give short-acting analgesia for 24–72 hours until fentanyl patch takes effect. Do not cut patches before application. Wear gloves when applying or removing patch because drug may be absorbed during handling. Do not apply heat over a patch. Heat increases drug absorption and may cause overdoses. Used patches may still contain drug. Dispose of used patches to prevent accidental exposure to others, especially children and pets.</td>
</tr>
</tbody>
</table>

Continued
be diminished. Hearing is the final sense to be lost. It is important for you to remember as you are caring for the patient and conversing with the family that your patient likely hears everything you are saying. Encourage the family to continue talking to the patient.

**CRITICAL THINKING**

**Mr. Johnson**

Mr. Johnson is in the final hours of his life and has become increasingly short of breath throughout the day. With each inspiration, his respirations are moist and noisy. Currently, his respiratory rate is 30 per minute, and you notice he is using his accessory muscles to breathe.

1. What is the cause of his noisy breathing?
2. What can be done to lower his respiratory rate and decrease his dyspnea?

*Suggested answers are at the end of the chapter.*

**CARE AT THE TIME OF DEATH AND AFTERWARD**

Death has occurred when you observe the absence of heartbeat and respirations. The skin becomes pale and waxy, the eyes may remain open, and pupils are fixed. Telling the family that the patient has died should be done with sensitivity, providing small amounts of information according to the family’s level of understanding. Be sure to check and adhere to the policies in your health care setting and state regarding death pronouncement and organ donation. Document the general appearance of the body, including absent pulse and lung sounds. Your goal now is to provide a personal closure experience for the family.

After death has been pronounced, you will provide **post-mortem care**. First, remove the tubes, medical supplies, and equipment. Bathing and dressing the patient and making him or her look presentable for the family shows respect. Some cultures dictate specific care of the body after death and who should provide that care (see Chapter 4 for more information). The nurse can assess and advocate for cultural practices requested by the family. Work toward providing a clean, peaceful impression of the deceased. Position the body in proper alignment, insert dentures, place dressings on leaking wounds, and use briefs as needed. Allow the family time with the body. Embalming is necessary within 12 hours. Do not remove the body from the room until the family is ready. Covering or uncovering the face at removal should be done according to the family’s preference. Additional activities, such as contacting the HCP or funeral home, should be carried out according to institutional policy.

**GRIEF**

Grief is the emotional response to a loss. Loss is a daily experience in everyone’s life. Loss can occur due to divorce, children leaving home, loss of job, loss of possessions, or other losses, including death. People express grief in their own way according to their coping skills, life experiences, and cultural
norms. In end-of-life care, grief is a process that begins before the patient’s death and continues through a series of tasks that the survivors move through to resolve grief. Feelings associated with grief may include anger, frustration, regret, guilt, sadness, and many others. Although each person is different, the process commonly includes three general stages (Table 17.4).

Interventions for the grieving patient are addressed in the “Nursing Care Plan for the Patient at the End of Life.” The nursing process for the grieving family is addressed next.

### NURSING PROCESS FOR THE GRIEVING FAMILY

#### Data Collection

Some things to consider when assessing grief include the following:

- Where is the family in the grief process?
- Are family members experiencing physical problems, such as shortness of breath, sweating, or skin color changes?
- Is the stress of grieving worsening medical conditions?
- What support systems are available to the family?
- What interventions can I use to facilitate their grief process?

#### Nursing Diagnoses, Planning, and Implementation

Although many nursing diagnoses may be appropriate, the priority diagnosis is simply Grieving.

**Grieving related to impending death or loss of loved one.**

**EXPECTED OUTCOME:** Family members will be able to express feelings of anger, guilt, or sadness. They will be able to think about the future and perform ADLs as needed.

- Simply be present. *Sitting with the bereaved, without having to have all the answers, is very powerful. If you don’t know what to say, just be silent.*

#### Evaluation

Healing takes time. If interventions have been effective, however, family members will have the support to function effectively while they grieve.

### THE NURSE AND LOSS

Working with dying patients triggers awareness of your own losses and fears about death and mortality. Adapting to the care of the dying requires that you explore and experience your personal feelings toward death. Unresolved losses from your past can resurface and affect your ability to care for dying patients. You may find that you continue to think about patients who have died long after the event. Emotionally continuing to care about deceased patients takes energy away from the daily care you are providing to current patients and your own family. Unresolved grief can lead to symptoms that resemble burnout, such as insomnia, headaches, and fatigue.

If you find yourself distancing and withdrawing from your dying patients, it is an indicator that you need to attend to caring for yourself. Some nurses may find counseling helpful to effectively process losses from the past and learn healthy ways to process future losses.

### Table 17.4 Stages of Grief

<table>
<thead>
<tr>
<th>Stage</th>
<th>Tasks</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stage 1</td>
<td>Acknowledge the reality of the loss. Recognize the loss.</td>
<td>Has difficulty with feelings of numbness, emotional outbursts, poor daily functioning, and avoidance.</td>
</tr>
<tr>
<td>Stage 2</td>
<td>Work through the pain by expressing and experiencing the feelings.</td>
<td>Anger, bargaining, depression. May feel guilt over not preventing the death or not providing enough care. May feel angry at loved one who has “left them behind.” May experience insomnia, loss of appetite, apathy, lack of interest in daily life.</td>
</tr>
<tr>
<td>Stage 3</td>
<td>Adjust to an environment without the deceased.</td>
<td>Finds hope in the future, participates in social events, feels more energetic.</td>
</tr>
</tbody>
</table>
Both formal and informal support systems should be in place to support staff through multiple losses. Informal support can be one-on-one sharing of experiences with coworkers, peers, pastoral counselors, and HCPs. Understanding and acknowledging your limitations, asking for help, and getting regular exercise and relaxation are important components. Some nurses find journal writing a helpful process; writing down feelings may allow you to release them. Formal support systems can be established in many ways:

- Preplanned gatherings where nurses can express feelings in a safe environment
- Postclinical debriefings after difficult deaths to alleviate anxiety and promote learning
- Ceremonies such as memorial services in facilities to allow both staff and residents to recognize and honor the loss of patients.

In addition, many employers offer free employee assistance programs that provide counseling.

**REFLECTIONS ON MR. MORAN**

Remember Mr. Moran from the beginning of the chapter? Clearly he is approaching the end of life. Determine what he and his family want to happen in the final months of his life and where he wants to be. What are the goals of care? If comfort is the goal, how can this best be achieved? If keeping him in his familiar and safe environment is the goal, then help his family weigh the benefits and burdens of CPR, hospitalization, artificial feeding, and artificial hydration.

**Home Health Hints**

- Allow time during your visit to sit quietly with the patient and caregiver. Sitting quietly lets the patient and caregiver know you are there to meet both physical and emotional needs.
- Encourage family involvement with care. Families need reassurance that they are not going to hurt the patient; take the time to teach them how to assist the patient with basic care.
- Prepare the family for what to expect as death approaches.
- When the patient is no longer conscious, encourage the family to continue to spend time at the bedside sharing personal thoughts and memories with the patient. For example, a spouse might talk about when they first met, or family members can play a favorite song.

**SUGGESTED ANSWERS TO**

**CRITICAL THINKING**

- **Mrs. Hart**
  1. Mrs. Hart will need a DNR order in the hospital setting and, when she goes home, she will need an out-of-hospital, prehospital, durable DNR or POLST—whatever is called for in her state of residence. In addition, her family members should be aware of her wishes.
  2. Her HCP, hospital social worker, or case manager can be helpful.

- **Mr. Johnson**
  1. Mr. Johnson’s noisy breathing may be caused by saliva collecting in the back of the throat or by pulmonary edema.
  2. Mr. Johnson may benefit from oxygen, positioning, and suctioning oral secretions. Low-dose morphine will decrease his respiratory rate and improve his oxygenation. Morphine also has a drying effect on secretions. If morphine is unsuccessful, the addition of hyoscyamine may be helpful.

**REVIEW QUESTIONS**

1. A 94-year-old patient is admitted from home to the hospital with pneumonia. What factors would lead the nurse to believe the patient is nearing the end of life?
   1. Distended abdomen and yellow skin tone
   2. Fever of 101.6°F (38.7°C) and a respiratory rate of 28 per minute
   3. Difficulty swallowing and weight loss
   4. Inability to cough and bring up secretions

2. What is a durable power of attorney for health care?
   1. A document that outlines a patient’s wishes at the end of life
   2. A document that gives a patient a “do not resuscitate” status
   3. A document specifying the person who will make decisions for a patient once the document is signed
   4. A document specifying the person who will make decisions for a patient when the patient is no longer able to speak for himself
3. A patient’s family member says, “I heard someone say my mother could have a ‘good death.’ What on earth is a good death?” Which response by the nurse is best?
   1. “We consider a good death to be one that follows the patient’s wishes for care, is comfortable, and allows them to die where they choose.”
   2. “In reality, no death is a good death, but we do our best to make sure patients are comfortable right up until they die.”
   3. “A good death is when the patient is kept sedated so they don’t really know what is happening during the last days until they die.”
   4. “A good death occurs when the patient is kept alive as long as possible, so she can take care of all her unfinished business first.”

4. A husband whose wife has just died cries, “What am I going to do? She is all I had.” What is the best response the nurse can provide?
   1. “You are going to go on with your life. You still have your work and your children.”
   2. “I am sorry you lost your wife, but I know she would not want you to be sad. You have to be strong for her.”
   3. “I know how you feel. I lost my grandmother recently, and it was really hard.”
   4. There is no need to say anything. Just be present and listen.

5. A dying patient has excessive secretions that are causing dyspnea. Which medications will best help dry the secretions and increase comfort? Select all that apply.
   1. Haloperidol
   2. Scopolamine
   3. Acetaminophen
   4. Morphine
   5. Guaifenesin

6. Which of the following nursing interventions should the nurse provide at the end of life? Select all that apply.
   1. Position the patient to increase comfort and prevent complications.
   2. Provide comfort measures such as massage.
   3. Research experimental treatments that may help the patient find a cure.
   4. Administer medications to control symptoms.
   5. Teach the family CPR for use if the patient dies when the nurse is not present.
   6. Sit quietly with the patient and family.

7. A patient has just died, and his family is waiting to see him. What postmortem care is essential first?
   1. Document the time and circumstances of the death.
   2. Place identification on the body according to hospital policy.
   3. Clean the patient up and make him look peaceful.
   4. Cover the patient’s body and face with a sheet.

8. The wife of a hospitalized patient who died an hour ago is crying and unwilling to leave the hospital room. The rest of the family is in the waiting room. The admitting department just called and wants to have the room cleaned for a new patient. Which action should the nurse take?
   1. Allow the wife to stay in the room as long as she likes.
   2. Call a taxicab for the wife and gently guide her out of the room.
   3. Sit with the wife for a few minutes, then take her to the waiting room.
   4. Tell the wife that you are sorry for her loss, but that another patient needs the room.

9. A patient who has been receiving hospice care for 3 months tells the LPN he has decided he wants to return to active treatment of his disease. What should the LPN do?
   1. Encourage the patient to discuss his desire with his HCP.
   2. Tell the patient that he cannot change his goals once hospice care has been initiated.
   3. Check his medication supply for any leftover medications he was taking during treatment.
   4. Explain to the patient that since he is terminal, treatment will not help the course of his disease.

Answers can be found in Appendix C.

Understanding the Immune System
KEY TERMS

- **active immunity** (AK-tiv im-YOO-nih-tee)
- **anaphylactic** (AN-uh-fih-LAK-tik)
- **antibody** (AN-tih-baw-dee)
- **antigen** (AN-tih-jen)
- **autoimmune** (AW-toe-ih-mewn)
- **cell-mediated immunity** (SELL mee-dee-ay-ted ih-MYOO-nih-tee)
- **humoral immunity** (HYOO-mur-uhhl ih-MYOO-nih-tee)
- **lymphocyte** (LIM-uh-site)
- **neutrophil** (NEW-troh-fil)
- **passive immunity** (PASS-iv ih-MYOO-nih-tee)
- **white blood cells** (WYTE BLUHD SELLS)

**LEARNING OUTCOMES**

1. Identify the type of immunity that is obtained with a vaccine.
2. Describe the two mechanisms of immunity.
3. Discuss the function of each class of immunoglobulin and how each behaves in a particular immune response.
4. Describe how aging affects the immune system.
5. Explain subjective data that are collected when caring for a patient with a disorder of the immune system.
6. Explain the objective data that are collected when caring for a patient with a disorder of the immune system.
7. Describe nursing care provided for patients undergoing diagnostic tests for the immune system.
8. Discuss common therapeutic measures used for disorders of the immune system.
Immunity is defined as the ability to destroy pathogens or other foreign material and to prevent further cases of infectious disease. Immunity is typically the body’s response to foreign microorganisms such as bacteria, viruses, and fungi. However, immune responses can be directed to ward other cells or substances that are identified by the body, correctly or incorrectly, as foreign. Malignant cells are considered foreign and are usually destroyed by the immune system after mutation but before they become malignant. Unfortunately, transplanted organs are usually perceived as foreign and are therefore rejected. Occasionally, the immune system mistakenly reacts to self (autoimmune disease) or to a substance that should be tolerated (allergic reaction).

The immune system consists of lymphoid organs and tissues, lymphocytes and other white blood cells (WBCs), and many chemicals that activate our own cells for the destruction of foreign antigens (Fig. 18.1). The lymphatic system includes lymph, lymphatic vessels that help return tissue fluid to the circulatory system; lymph nodes, nodules, and the spleen, where macrophages phagocytize (engulf and destroy) pathogens and B and T cells carry out immune functions; and red bone marrow and the thymus (which functions primarily in childhood and atrophies with age). Lymph flows from vessels through lymph nodes where pathogens are percolated out and destroyed. Lymph nodes are especially concentrated in the cervical, axillary, and inguinal areas. Lymph nodules, lacking encapsulation, are found under the surface of mucous membranes (e.g., tonsils).

Antigens
Antigens are chemical markers that identify cells or molecules. Human cells have their own antigens—thousands of markers that identify the cell as “self.” These are the major histocompatibility complex antigens, also called human leukocyte antigens, which are genetically determined. Major histocompatibility complex antigens are tolerated by the body’s immune system, whereas foreign antigens will be destroyed in one of several ways.

Lymphocytes
There are three types of lymphocytes: natural killer (NK) cells, thymus-derived lymphocytes (T cells), and bone marrow–derived lymphocytes (B cells), each with different functions.

Natural Killer Cells
NK cells are found throughout the body and are nonspecific in action, destroying a variety of foreign cells including altered self-cells. After binding with an abnormal cell, NK cells release either perforins or granzymes, which cause cytolyis. Cell fragments are then phagocytized by WBCs.

T Cells and B Cells
The lymphocytes called T cells and B cells are in volved in specific immune responses; that is, each cell is programmed to respond to one kind of foreign antigen.

Antibodies
Antibodies are also called immunoglobulins (Ig) or gamma globulins and are glycoproteins produced by plasma cells in response to foreign antigens. Antibodies do not themselves destroy foreign antigens but rather become attached to such antigens to label them as foreign.
them for destruction. Each antibody is specific for only one antigen, and B cells (that become plasma cells) are capable of producing millions of different antibodies. There are five classes of human antibodies, designated by letter names: IgG, IgA, IgM, IgD, and IgE (Fig. 18.2). Their functions are summarized in Table 18.1.

**Mechanisms of Immunity**

The two mechanisms of immunity are **cell-mediated immunity**, which involves T cells, and **humoral immunity**, which involves mainly B cells but is assisted by T cells. Although the mechanisms are different, invasion by a pathogen often triggers both.

**Cell-Mediated Immunity**

This mechanism of immunity is effective against intracellular pathogens (such as viruses or fungi), malignant cells, and grafts of foreign tissue. A T-cell response results in cytotoxic Ts, which attack altered cells; helper Ts, which assist; and memory Ts, which retain knowledge of the pathogen in the event of future encounters with the same (Fig. 18.3).

**Humoral Immunity**

Humoral immunity is also called *antibody-mediated immunity* and involves antibody production. It is effective against extracellular pathogens, which are usually bacteria but can also be viral or fungal infections (Fig. 18.4).

Although B cells are stationary, the antibodies produced by plasma cells circulate throughout the body and bond to the antigen, forming an antigen–antibody complex. This immobilizes the bacteria; also, the antigen is now labeled for phagocytosis by macrophages or neutrophils. The antigen–antibody complex also activates the complement cascade.

* **WORD BUILDING**
  * neutrophil: neutro—neuter + philo—to love

</tbody>
</table>

Complement is a group of more than 30 plasma proteins that circulate in the blood until activated by either the presence of foreign bacteria or by an antigen–antibody complex. The activation of complement results in the formation of a protein cascade that lyses (causes disintegration of) the cell. Other complement proteins bind to foreign antigens and serve as further labels to attract macrophages.

**ANTIBODY RESPONSES**

The first exposure to a foreign antigen stimulates antibody production, but the antibodies are produced too slowly to prevent the disease. However, with time, the person accumulates antibodies and memory cells specific for that pathogen. On a second exposure to the antigen, the memory cells begin rapid production of large amounts of antibody, often enough to prevent a second occurrence of the illness (Fig. 18.5). This is the basis for the protection given by vaccines. A vaccine contains an antigen that is not pathogenic. The vaccine stimulates the formation of antibodies and memory cells.

Antibodies may also neutralize viruses; that is, they attach to a virus and render it unable to enter a cell (see Fig. 18.2). Viruses cannot reproduce outside of living cells, and those coated with antibodies are phagocytized by macrophages. Interferon, another defense against viruses, is a chemical produced by cells infected with viruses. Although it does not help the infected cell, interferon protects surrounding cells by enabling them to resist viral replication.

Antibodies are also involved in allergic responses, in which the immune system responds to foreign but harmless antigens (an allergen), such as plant pollen. IgE antibodies bond to mast cells, which break down and release histamine and other chemicals that contribute to inflammation. Anaphylactic shock is an allergic reaction, but massive response. It is characterized by loss of plasma from capillaries (an effect of histamine) and a sudden drop in the intravascular blood volume and blood pressure.

**TYPES OF IMMUNITY**

Two categories of immunity are passive immunity and active immunity. In passive immunity, antibodies are not produced by the person but are obtained from another source. One form

- **WORD BUILDING**
  - anaphylactic: ana—up + phylaxis—protection
of naturally acquired passive immunity includes placental transmission of antibodies from mother to fetus and transmission of antibodies in breast milk. Artificially acquired passive immunity involves injection of preformed antibodies; this may help prevent disease after exposure to a pathogen such as the hepatitis B virus. Passive immunity is always temporary, in that antibodies from another source eventually break down.

Active immunity means that the person produces his or her own antibodies. An example of naturally acquired active immunity occurs when a person recovers from an infection and then has antibodies and memory cells specific for that pathogen. Artificially acquired active immunity occurs as the result of a vaccine that stimulates production of antibodies and memory cells. The duration of active immunity depends on the particular disease or vaccine; some confer lifelong immunity, but others do not.

Gerontological Issues

Significant changes occur in the immune system of the older adult. These changes are known as immune senescence, which refers to a decline in immune system function. Some specific changes include the following:

- Thymus gland decreases in size, increases production of immature T cells, and has a subsequent decline in response to antigens.
- Antibody response to foreign organisms decreases.
- Immunizations to support the immune responses of older adults include the following:
  - Influenza vaccine (plus H1N1 flu vaccine if recommended) yearly mid-October to mid-November, before influenza season
  - Pneumococcal vaccine once when age 65
  - Herpes zoster vaccine once when age 60
  - Tetanus, diphtheria, and pertussis booster every 10 years.

Aging and the Immune System

The efficiency of the immune system decreases with age (Fig. 18.6). As such, older adults are more susceptible to infections and autoimmune disorders (see “Gerontological Issues”). The incidence of cancer is also higher; malignant cells that might once have been quickly destroyed by the immune system live and proliferate.
History

Demographic Data
The patient’s gender and ethnicity are important to note because some diseases tend to be associated with a particular gender or ethnicity. For instance, systemic lupus erythematosus (SLE; see Chapter 19), an autoimmune disorder, affects women up to nine times more than men (Ferenkeh-Koroma, 2012). In addition, Hispanic, Native American, Asian, and African American women develop SLE two to three times more often than Caucasian women.

Health History

Assessment of the patient’s past and present medical conditions should also include a family history. Many atopic (allergic) disorders, such as allergic rhinitis and asthma (see Chapter 31), and autoimmune disorders, such as ankylosing spondylitis (see Chapter 19), are thought to be either familial or have a genetic predisposition in certain ethnic or cultural groups (“Cultural Considerations”). For example, 4 new genes have been identified that are strongly associated with SLE, and 10 others are possible risk factors.

Patients’ surgical history may give clues about their previous health or current condition. For example, with thymus gland removal (thymectomy), T-cell production may be altered, which affects the cell-mediated immune response. If the spleen was removed (splenectomy), lymphocyte and plasma cell production may be altered, which affects the humoral immune response.

NURSING ASSESSMENT OF THE IMMUNE SYSTEM

Disorders of the immune system can affect every system in the body, so it is important to collect head-to-toe data as well as a patient history (Table 18.2).
### TABLE 18.2 SUBJECTIVE DATA COLLECTION FOR THE IMMUNE SYSTEM

<table>
<thead>
<tr>
<th>Category</th>
<th>Questions to Ask During the Health History</th>
<th>Rationale/Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Demographic Data</strong></td>
<td>What is your age?</td>
<td>The immune system decreases in functional effectiveness as one ages, and a number of immune disorders tend to afflict individuals of particular age ranges.</td>
</tr>
<tr>
<td></td>
<td>Where were you born? What is your ethnic or cultural background?</td>
<td>This information can aid in determining ethnic and cultural background influences. Some immune disorders tend to afflict individuals of particular cultural/ethnic groups more than others.</td>
</tr>
<tr>
<td></td>
<td>Where have you lived? Where do you currently reside?</td>
<td>This information can aid in determining ethnic and cultural background as well as possible environmental influences.</td>
</tr>
<tr>
<td><strong>History</strong></td>
<td>Do you have allergies to any medications? Latex? Foods? Insects? Environmental allergens? If yes, have you had a recent exposure to any of these? Describe the reaction.</td>
<td>This information may lead to a direct cause of current symptoms and provides information regarding the status of the patient’s immune system. Medication side effects are commonly inaccurately considered allergies by patients. If family members (especially immediate) have severe reactions to substances, the patient may be predisposed to immune reactions to the same antigen or in general.</td>

<tr>
<td></td>
<td>What sort of support systems do you have?</td>
<td></td>
</tr>
</tbody>
</table>
For current medications, include prescription drugs, over-the-counter drugs, and herbal preparations. Corticosteroids and immunosuppressants decrease the immune response, and some anti-infectives and antineoplastics depress the bone marrow. This results in decreased production of the cells made in the bone marrow. Bone marrow depression of WBCs can alter cell-mediated and humoral immune responses. The herbal preparation licorice, which is sometimes used for its anti-inflammatory and expectorant effects, when taken with corticosteroids, increases the effects of the corticosteroids.

A patient’s lifestyle may influence immune system function and should be assessed. Knowing a patient’s dietary habits and supplemental vitamins gives insight into the potential reserve of the patient’s immune system for fighting infection. Anaphylactic reactions can be caused by exposure to latex, which may be found in gloves and other medical products that healthcare workers and their patients touch. Be aware of this potentially life-threatening reaction, and know the agency’s latex allergy protocol. Patients who are allergic to latex should wear medical identification jewelry or have other readily available identification and carry an epinephrine auto-injector (EpiPen).

The patient’s life stressors, coping behaviors, and support systems should be explored. Stress (environmental, physical, and psychological) can depress immune system function. Coping behaviors are essential to keep stress within manageable limits to maintain optimum immune function. Support systems play an important role in coping with stress and should be encouraged and nurtured by nurses.

Current Problem

Use the WHAT’S UP? format to collect data about the current immune system problem. For immune disorders, ask the patient the following questions:

- Where is it? What part of the body is affected?
- How does it feel? Painful? Itching?
- Aggravating and alleviating factors?
- Timing: Was there exposure to a pathogen? Did you have a previous infection? Does it occur only in certain settings? Did you have chemotherapy or radiation therapy? How long have symptoms persisted?
- Severity. Does it affect activities of daily living (ADLs)? Work? Roles?
- Useful data for associated symptoms. Imunosuppression? Family history? Allergies?
- Perception of the patient of the problem. What do you think is wrong?

Common signs and symptoms present with immune disorders include fever, fatigue, joint pain, swollen glands, weight loss, and rash.

Physical Examination

Physical data collection begins by observing the patient’s general appearance, color, posture, gait, facial expression, skin, and nailbeds (Table 18.3). Any cyanosis or erythema (redness) is noted. Rashes should be examined for size, shape, location, texture, drainage, and pruritus (itching). Visual and hearing changes can be associated with an immune disorder. Adventitious lung sounds, such as wheezing, may indicate asthma or an allergic response. Crackles are often associated with upper respiratory infection. Lymph nodes should be inspected and then gently palpated (by the advanced practitioner; see Fig. 18.1). Normally, lymph nodes are not palpable in the adult. If enlarged, note the following characteristics: location, size, shape, tenderness, temperature, consistency, mobility, symmetry, pulsation, and if red streaks, redness, or edema are present.

LEARNING TIP

A normally functioning immune system is required to trigger an inflammatory response and production of the signs of inflammation or infection: fever, redness, pain, swelling, and warmth. If the immune system is suppressed or functioning abnormally, this normal inflammatory response may not occur. Thus, the patient may have only a low-grade fever with none of the other signs of inflammation or infection (redness, pain, swelling, and warmth).

Recognize patients with suppressed immune systems so that low-grade fevers are reported to the physician for prompt treatment. This may be the only sign of a life-threatening infection that develops because of the suppressed immune system.

<td>Confusion or lethargy are common in later stages of systemic lupus erythematosus (SLE) and acquired immunodeficiency syndrome (AIDS).</td>
</tr>
</tbody>
</table>
| **Skin**          | Warm, dry, smooth, supple, even coloring, nonpruritic | Rash, urticaria, pruritus, pustules with many forms of allergic reactions.  
Butterfly rash (red rash over bridge of nose and cheek bones) occurs in less than 50% of patients with SLE.  
Painless purple lesions with Kaposi’s sarcoma, associated with HIV and AIDS.  
“Butterfly rash” (red rash over bridge of nose and cheek bones) occurs in less than 50% of patients with SLE.  
Painless purple lesions with Kaposi’s sarcoma, associated with HIV and AIDS. |
| **Lung Sounds**   | Clear throughout                               | Pericardial friction rub may be heard with rheumatoid arthritis or SLE because of inflammation of the connective tissue surrounding the heart (pericardium). |
| **Lymph Nodes**   | Nonpalpable and nontender                      | Enlarged lymph nodes that are painless, firm, and fixed are associated with cancerous lesions, whereas painful enlarged lymph nodes are associated with inflammation and infection. |
| **Gastrointestinal** | Appropriate appetite without nausea or vomiting  
Regular pattern of brown, soft, formed stools | Anorexia, nausea, and vomiting associated with immune disorders.  
Diarrhea or diarrhea alternating with constipation is common with irritable bowel syndrome (IBS). |
| **Renal**         | An average of 30 mL per hour of clear, yellow/amber urine without presence of protein or pain | Urine output of less than 30 mL/hour, the presence of protein in urine, and edema occur with SLE or serum sickness.  
Transfusion reactions can cause hematuria, flank pain, or oliguria.  
Glomerulonephritis may cause hematuria, flank pain, or oliguria. |
| **Musculoskeletal** | Painless and nonswollen joints with full range of motion  
Overall strength, endurance and coordination appropriate for age and physical fitness | Swollen, painful joints and limited joint range of motion occur in rheumatoid arthritis.  
Decreased strength and coordination occur in patients with multiple sclerosis.  
Patients with myasthenia gravis lose strength and endurance with repetitive movements. |
If enlarged, the spleen may be palpable (by an advanced practitioner) in the left upper quadrant of the abdomen with disorders in which there is an overproduction or excessive destruction of red blood cells (RBCs).

Renal impairment from an immune disorder causes a change in urinary output, flank pain, edema, weight gain, or elevated renal function studies.

A general neurologic assessment of muscle strength and coordination, changes, or abnormalities is made. Changes may be an indication of an immune-based disorder such as multiple sclerosis or myasthenia gravis.

**CRITICAL THINKING**

**Mrs. Sims**

- Mrs. Sims is scheduled for a lymph node biopsy and is seen in preadmission testing before surgery. As the nurse prepares to draw blood specimens, he learns that Mrs. Sims is allergic to latex.

1. How can the nurse promote patient-centered care during this lab draw?
2. Why is this patient allergy information important?
3. What should the nurse do next?
4. What precautions should the nurse use for drawing the blood specimen?

Suggested answers are at the end of the chapter.

**DIAGNOSTIC TESTS FOR THE IMMUNE SYSTEM**

Presenting signs and symptoms and the patient’s history determine which tests and procedures may be ordered. Table 18.4 describes the most common blood tests for patients with allergic, autoimmune, or immune disorders. Table 18.5 presents common noninvasive and invasive procedures for immune disorders. Chest X-ray, magnetic resonance imaging (MRI), and computed tomography (CT) scans might also be useful.

**Gene Testing**

With human genome mapping data, scientists are able to test for numerous diseases, predisposition to diseases, and enzyme deficiencies that can alter immune response.

**THERAPEUTIC MEASURES FOR THE IMMUNE SYSTEM**

**Allergies**

With allergies, medical identification jewelry or other readily available identification is essential. Allergies must be verified before giving any medications or foods. All allergies, including those to food, must be taken very seriously (see “Evidence-Based Practice”).

**EVIDENCE-BASED PRACTICE**

**Clinical Question**

If a patient is allergic to shellfish, is the person allergic to iodine and therefore unable to tolerate iodine in products such as Betadine, Povidone being used on the skin?

**Evidence**

True hypersensitivity reactions to seafood, including shellfish, arise from the group of antigens called tropomyosins, which are proteins needed for muscle contraction. These reactions are not caused by iodine in the seafood (Harrison, 2013).

**Implications for Nursing Practice**

Although nurses need to continue to ask patients about their allergies, there is no need to exchange the povidone-iodine solution found in procedural kits for a non-iodine-based bactericidal cleanser in patients with seafood allergies.

C-Reactive Protein (CRP)

An abnormal protein found in plasma during acute inflammatory processes; more sensitive than sedimentation rate. Normal: <10 mg/L

Radioallergosorbent test (RAST)

Patient serum is mixed with a specific allergen, incubated with radiolabeled anti-IgE antibodies, and then the total amount of the specific IgE antibodies is measured.

Enzyme-Linked Immunosorbent Assay (ELISA)

Patient’s blood is tested for antibodies on HIV antigen test plates.

Western Blot

A blood test to detect the presence of any of the four major HIV antigens. Is considered positive when at least two of the four antigens are detected. Used as a confirmation test.

Immunoglobulin Assay or Electrophoresis

Antibodies are made up of immunoglobulins, of which there are five different classes.

- IgG
  
  Normal (mg/dL):
  
  500–1500

- IgM
  
  50–300

- IgA
  
  100–490

- IgE
  
  <100 IU/mL

- IgD
  
  <3 U/mL

CD4+ Count

CD4+ T lymphocytes are counted. Percentage: 60%–75% Normal count: 600–1500/mm³

CD8 + Count

CD8+ T lymphocytes are counted. Percentage: 25%–30% Normal count: 300–1000/mm³

CD4+/CD8 + Ratio

Ratio of CD4+ and CD8+ absolute counts are determined. Normal: >1

AIDS = autoimmune deficiency syndrome; HIV = human immunodeficiency virus; MCH = mean corpuscular hemoglobin; MCHC = mean corpuscular hemoglobin concentration; MCV = mean corpuscular volume; NSAIDs = nonsteroidal anti-inflammatory drugs; RBC = red blood cell; RDW = red blood cell distribution width; SLE = systemic lupus erythematosus; WBC = white blood cell.

</tbody>
</table>
Food allergies create serious management problems and have become the most common cause of anaphylaxis in the community setting, resulting in numerous deaths from anaphylactic shock (“Nutrition Notes”). The offending allergen may be present in extremely small amounts. Sometimes a food product is contaminated by a previous batch of food made with the same equipment. Occasionally, the allergen may enter the body not by ingestion but by inhalation or contact with skin or mucous membranes.

Epinephrine is the drug of choice for life-threatening anaphylactic reactions. If possible, treatment should be given immediately with administration of epinephrine until other medical care can be provided.

An epinephrine autoinjector (EpiPen) is commonly prescribed for patients with allergies to food or insect stings. It is a prepackaged, single-use device that allows the patient to self-inject a physician-ordered dose of epinephrine right through clothing. The patient must carry the EpiPen at all times when insect stings are possible. The expiration date of the EpiPen must be checked routinely and replaced as needed. The patient should be instructed that the EpiPen does not replace the need for immediate and continued medical attention because the duration of the single dose of epinephrine varies from 1 to 4 hours. Also, anaphylaxis can be biphasic, which means a relapse can occur hours after the initial improvement from the dose of epinephrine.

Nutrition Notes

Respecting Food Allergies

Allergies and Anaphylaxis

In the community, food is the most common trigger of anaphylaxis, which can be fatal (Sicherer, 2011). Epinephrine is the drug of choice for acute reactions and the only medication shown to be lifesaving when administered promptly, but it is underutilized (Chipps, 2013). An analysis of 13 anaphylactic reactions to food in children, 6 of which were fatal, illustrates the criticality of epinephrine: mean elapsed time between ingestion of the allergenic food and a dose of epinephrine was 36 minutes in the survivors and 93 minutes in the deceased. Despite histories of asthma and food allergies, fewer than half the children had self-injectable epinephrine prescribed, and only one of the six children with a fatal reaction used a dose (Boch, Munoz-Furlong, & Sampson, 2001). Analysis of 63 later cases of fatal anaphylaxis caused by food allergies confirmed the original findings (Boch, Munoz-Furlong, & Sampson, 2007).

Guidelines for Treating Anaphylaxis

Guidelines specify that all patients who have experienced anaphylaxis should be discharged with (1) an anaphylaxis emergency action plan, (2) an epinephrine autoinjector (2 doses), (3) a plan for monitoring autoinjector expiration dates, (4) a plan for arranging further evaluation, and (5) printed information about anaphylaxis and its treatment (Burks et al, 2011). More education at all levels—physicians, patients, families, school personnel, restaurateurs, and the public—is required to combat these potentially preventable tragedies. Food allergies deserve more respect and timely treatment.

Immunotherapy

To help desensitize a patient with anaphylactic reactions or chronic allergic symptoms, subcutaneous immunotherapy (SCIT) involves preparing an extract of the allergen and injecting small amounts of it as a vaccine. Initially, the subcutaneous injections are given once or twice weekly with a very dilute preparation. Over a 3- to 6-month period, the concentration of the allergen in the vaccine is increased until the desired hyposensitivity is reached. Once the desired allergen concentration is reached, maintenance injections may be given every few weeks, usually for up to 3 to 5 years. It is important that the patient not miss a dose. If this happens, the allergen strength may need to be reduced.

Clinical trials are ongoing in the United States using the sublingual (under the tongue) route as an alternate to subcutaneous injections. Sublingual immunotherapy (SLIT) is the use of tablets or drops containing specific allergen extracts placed under the tongue and allowed. It is popular in Europe, South America, Asia, and Australia. It has been found to have advantages over SCIT in a few select situations, such as when older people experience allergic rhinitis from house dust mites.

When administering the allergen injection, it is important to understand that an anaphylactic reaction can occur. A physician and emergency equipment should be readily available. After the injection, the patient should be observed for about 20 to 30 minutes to detect a reaction. The patient and family should be taught that a reaction could occur up to 24 hours after the injection and how to respond if it does occur. Local inflammatory reactions are much more common than anaphylaxis and can be minimized by giving a histamine blocker before giving the vaccine.

Medications

Medications are one of the primary treatment options for immune disorders. General categories of these medications include epinephrine, corticosteroids, antihistamines, histamine (H1) blockers, decongestants, mast cell stabilizers, antibiotics, immunosuppressants, interferon, leukotriene antagonists, and hormone therapy (see Chapter 19).

Surgical Management

In some cases, splenectomy is needed to control symptoms of an immune disorder. It usually is done when other lines of treatment are not effective. A significant side effect of this surgery is the reduced ability of the immune system to fight infections.

Monoclonal Antibodies

Monoclonal antibodies can be produced against a variety of antigens. A monoclonal antibody is made by cloning one specific antibody and then growing unlimited amounts of it in tissue cultures. Many uses are being found for these antibodies, such as in dealing with transplant rejections.

Recombinant DNA Technology

Recombinant deoxyribonucleic acid (DNA) technology combines genes from one organism with genes from another. This therapy is used to replace an abnormal or missing gene with the goal of producing a normal gene. The normal gene can then be injected into the patient in an attempt to cure the disorder if the patient’s body reproduces the normal genes. T-lymphocyte-directed gene transfer for severe combined immune deficiency has been performed successfully. Along these same lines is the research regarding injection of stem cells, the precursors to all cells, into abnormal areas to produce normal cells. Studies continue in this area for possible uses of gene therapy. Since the completion of the mapping portion of the human genome project, new discoveries in this area occur daily. For more information, visit www.nhgri.nih.gov or www.ncbi.nlm.nih.gov/guide.
UNIT FOUR  Understanding the Immune System

SUGGESTED ANSWERS TO

CRITICAL THINKING

Mrs. Sims

1. Review the patient’s history and allergies to prevent complications. Explain the procedure, and allow the patient to ask questions or verbalize concerns.
2. The patient may have an anaphylactic reaction if exposed to latex, which can result in death for some patients.
3. The nurse should follow the agency’s latex allergy protocol, enter this information into the patient’s medical record, notify surgery scheduling so latex precaution protocols can be planned for surgery, and ensure that the patient’s health care provider is informed.
4. Following the agency’s protocol, the nurse should wear nonlatex gloves and use nonlatex equipment to draw the specimens.

REVIEW QUESTIONS

1. The nurse taught a patient about vaccines. The nurse would evaluate the patient as understanding the information taught if the patient stated that a vaccine provides which of these types of immunity?
   1. “Naturally acquired passive immunity”
   2. “Artificially acquired passive immunity”
   3. “Naturally acquired active immunity”
   4. “Artificially acquired active immunity”

2. Which of the following vaccines would the nurse correctly recommend to be given annually during a teaching session on health maintenance with an older patient?
   1. Influenza
   2. Pneumovax
   3. Diphtheria tetanus
   4. Polio

3. The nurse is assisting with data collection on a patient. Which of the following past surgeries found in the patient’s history would alert the nurse to possible immune system dysfunction when planning care?
   1. Splenectomy
   2. Thyroidectomy
   3. Pneumonectomy
   4. Parathyroidectomy

4. During data collection, the patient reports tenderness in the cervical lymph nodes. The nurse recognizes that enlarged and tender lymph nodes usually indicate which of the following problems?
   1. Cancer
   2. Degeneration
   3. Inflammation
   4. Arthritis

5. The nurse is caring for a patient with suspected HIV infection. The nurse anticipates that which of the following is a confirmation test that will be ordered to test for HIV antibodies?
   1. Murex SUDS
   2. Western blot
   3. Enzyme-linked immunosorbent assay
   4. p24 antigen testing

6. Biaxin 200-mg oral suspension is ordered for a patient. The nurse has 125 mg/5 mL available. How many milliliters should the nurse give?
   Fill in the blank.
   Answer: ______ mL

Answers can be found in Appendix C.

Nursing Care of Patients With Immune Disorders

SHARON M. NOWAK

LEARNING OUTCOMES

1. Explain the immunological mechanism for the four types of hypersensitivities.
2. Explain the pathophysiology of disorders of the immune system.
3. Identify the etiologies, signs, and symptoms of immune system disorders.
4. Plan nursing care for patients undergoing tests for immune system disorders.
5. Describe current medical treatment for immune system disorders.
6. List data collected when caring for patients with disorders of the immune system.
7. Explain factors that alter or influence the self-recognition portion of the immune system.
8. Plan nursing care for patients with disorders of the immune system.

KEY TERMS

- anaphylaxis (AN-uh-fih-LAK-siss)
- angioedema (AN-gee-oh-eh-DEE-mah)
- ankylosing spondylitis (ANG-kih-LOH-sing SPOND-y-litiss)
- histamine (HISS-tah-mean)
- urticaria (UR-tih-KAIR-ee-ah)
Disorders of the immune system can be divided into three categories. The first category is hypersensitivity reactions, which include conditions such as anaphylaxis, hemolytic transfusion reactions, measles, and transplant rejections. Autoimmune disorders (e.g., rheumatoid arthritis, ulcerative colitis, and multiple sclerosis) are the second category. The third category includes the immune deficiencies, such as hypogammaglobulinemia and acquired immunodeficiency syndrome (AIDS; see Chapter 20).

**HYPERSENSITIVITY REACTIONS**

The immune system is an adaptive system that protects the body. However, sometimes this system can cause injury to the body because of its exaggerated response. One of these occasions is when a hypersensitivity reaction occurs. In 1963, Gell and Coombs developed a system of classifying hypersensitivity reactions as types I, II, III, and IV, according to the way the tissue is injured.

**Type I Hypersensitivity Reaction**

An anaphylactic reaction, a type I reaction, is an immediate reaction that occurs on exposure to a specific antigen (Fig. 19.1). The reaction can range from mild to severe and life threatening. The patient must have had previous exposure (sensitization) to the antigen. During this exposure, immunoglobulin E (IgE) antibodies are made and attach to mast cells throughout the body. When a subsequent exposure occurs, the antigen causes IgE to trigger mast cells to release their contents. One of the substances released is histamine, which causes vasodilation, changes in vascular permeability, an increase in mucous production, and contraction of various smooth muscles.

If the second antigen exposure is localized, the reaction is mild and remains local. However, if the exposure is systemic, the reaction is massive and widespread. Respiratory allergies, such as allergic rhinitis and allergic asthma, with associated disorders of atopic dermatitis, tend to be reactions of a larger scale. Anaphylaxis, urticaria, and angioedema are the severest forms of type I reactions.

A type I reaction occurs when the patient has a positive reaction to a scratch test. A scratch test is done to identify specific allergens to which a patient is reactive. Tiny amounts of a variety of common allergens are scratched onto the skin,
which is then observed for indications of a reaction: redness, edema, and pruritus. If these indicators occur it is considered to be a local reaction.

**Allergic Rhinitis**

Allergic rhinitis is the most common form of allergy. When symptoms occur throughout the year, it is called perennial allergic rhinitis. If the symptoms occur seasonally it is called hay fever. The causative antigens are environmental and airborne.

**PATHOPHYSIOLOGY.** Allergic rhinitis is the result of an antigen–antibody reaction. Ciliary action decreases and mucous secretions increase. Vasodilation and local tissue edema occur.

**SIGNS AND SYMPTOMS.** Signs and symptoms vary in intensity and include sneezing, nasal itching, profuse watery rhinorrhea (runny nose), and itchy red eyes. The nasal mucosa is pale, cyanotic, and edematous. Frequently there are dark circles under the eyes, called allergic shiners, caused by venous congestion in the maxillary sinuses.

**DIAGNOSTIC TESTS.** Skin testing may be performed to identify the specific offending allergens to allow avoidance of the allergen. However, skin testing does not always identify the allergen, and has limited usefulness for allergens that cannot be easily avoided once identified. The in vitro allergy test or radioallergosorbent test (RAST), can be a beneficial alternative to skin testing for some patients.

**THERAPEUTIC MEASURES.** Initial treatment involves eliminating the offending environmental stimuli. Antihistamines and nasal decongestants may be prescribed to relieve symptoms. If the symptoms are severe, corticosteroids may also be given via inhalation or nasal spray. Rinsing the sinuses can be an inexpensive and effective way to reduce nasal congestion. Key to this intervention is to avoid introducing microorganisms into the nasal passage. The saline solution must be either sterile or made from distilled water or previously boiled then cooled water.

Rhinophototherapy uses light waves to reduce the hyperimmune response seen in this disorder. The treatment is usually done three times a week for 3 weeks and relieves symptoms such as sneezing, itching, and runny nose.

Immunotherapy, referred to as allergy shots, is reserved for patients with severe or debilitating symptoms (see Chapter 18). This therapy continues until the patient no longer has symptoms when exposed to the environmental antigen.

**Atopic Dermatitis (Eczema)**

Atopic dermatitis, often called eczema, is a familial, chronic inflammatory skin response.

**PATHOPHYSIOLOGY.** These skin lesions are not typical for a type I hypersensitivity reaction, and a specific antigen cannot usually be identified as the cause. However, the pathophysiology of atopic dermatitis is believed to be a type I hypersensitivity reaction, mediated by IgE antibodies, because it is commonly found in patients with allergic rhinitis or allergic asthma.

**SIGNS AND SYMPTOMS.** Initially there is pruritus, edema, and extremely dry skin, which is followed by eruptions of tiny vesicles (blisters); these eventually break open, crust over, and scale off. There is decreased sweating in these areas with the skin eventually thickening (lichenification) in the areas of dermatitis.

**DIAGNOSTIC TESTS.** There are no tests to confirm this diagnosis. A detailed history and physical examination are used to diagnose it and to exclude other diseases with similar symptoms. Serum IgE levels will be elevated in these patients and tend to correlate with the severity of the disease. If an infection is present, culture and sensitivity tests may be ordered to determine the infecting organism and appropriate treatment.

**THERAPEUTIC MEASURES.** Treatment focuses on the symptoms of pruritus and dry and inflamed skin. Antipruritics are vital in reducing the itch–scratch cycle that predisposes the patient to lesion infections. Lukewarm soaks followed with application of emollients and oil-in-water lubricants such as Alpha Keri oil tend to be the most effective for dryness. Topical corticosteroids may be ordered for their anti-inflammatory properties. Topical calcineurin inhibitors such as tacrolimus and pimecrolimus also reduce the inflammatory response and relieve itching and rash when steroids are not effective. If skin lesions become infected, topical or systemic antibiotics are prescribed. Dilute bleach soaks may also be used twice a week to reduce severity of symptoms, especially those of infection. For long-term management of symptoms, it is important to identify and eliminate the triggers of the hypersensitivity, while controlling environmental temperature and humidity.

**Anaphylaxis**

Anaphylaxis is a severe systemic type I hypersensitivity reaction. Table 19.1 lists the numerous possible causes of anaphylaxis.

Continued
PATHOPHYSIOLOGY. IgE antibodies produced from previous antigen sensitization are attached to mast cells throughout the body. In this reaction, the antigen is introduced at a systemic level, which causes widespread release of histamine and other chemical mediators contained within the mast cells. The most profound complications of an anaphylactic reaction are respiratory and cardiac arrest. Immediate treatment is needed to prevent death.

SIGNS AND SYMPTOMS. Anaphylaxis produces sudden and life-threatening signs and symptoms (Table 19.2). Generalized smooth muscle spasms occur, causing bronchial narrowing and creating stridor, wheezing, dyspnea, and laryngeal edema, which can lead to respiratory arrest. Cramping, diarrhea, nausea, and vomiting also result from these spasms. Capillary permeability increases, allowing fluid to shift from the vessels to the interstitium. This causes hypotension, tachycardia, and an increase in respiratory symptoms. The blood volume in the vessels decreases while the blood vessels dilate, resulting in a further decrease in circulating blood volume. The dilation also causes diffuse erythema (redness) and warmth of the skin. Neurologic changes include apprehension, drowsiness, profound restlessness, headache, and possible seizures.

| Therapeutic Measures      | Intravenous (IV) access  |
|                          | Epinephrine IV           |
|                          | Vasopressive drugs IV    |
|                          | (dopamine)               |
|                          | Oxygen                   |
|                          | Antihistamines (oral, IV, injection) |
|                          | Corticosteroids (oral, IV, injection) |

If severe respiratory compromise:

- Tracheostomy or endotracheal intubation
- Mechanical ventilation

| Complications             | Respiratory and cardiac arrest |

| Priority Nursing Diagnoses| Impaired Gas Exchange |
|                         | Anxiety                |
|                         | Ineffective Health Maintenance |
DIAGNOSTIC TESTS. There is no time for tests to be performed during an anaphylactic reaction other than those needed to guide symptom treatment, such as arterial blood gases or electrocardiogram (ECG) monitoring. Anaphylaxis is diagnosed based on physical assessment and history from the patient or significant other. After the patient’s recovery, allergen testing may be considered for future prevention.

THERAPEUTIC MEASURES. Intravenous (IV) access is a priority for administration of IV epinephrine, vasoressor drugs (dopamine), and fluids to increase blood pressure. Oxygen therapy is started. If respiratory symptoms are severe, a tracheostomy or endotracheal intubation may be needed, with mechanical ventilation. Antihistamines and corticosteroids may also be given.

URTICARIA

PATHOPHYSIOLOGY AND ETIOLOGY. Urticaria (hives) is a type I hypersensitivity reaction. It is triggered by the antigen-stimulated reaction of IgE antibodies, which causes the release of mast cell contents, especially histamine. The causes of urticaria are numerous. In addition to medications and foods, cold, local heat, pressure, and stress can also cause urticaria. Many patients with underlying chronic conditions, such as systemic lupus erythematosus (SLE), lymphoma, hyperthyroidism, or cancer, are susceptible to urticaria.

SIGNS AND SYMPTOMS. The lesions of urticaria are raised, pruritic, nontender, and erythematous wheals on the skin. They tend to be concentrated on the trunk and proximal extremities.

DIAGNOSTIC TESTS. Diagnosis is based on physical examination and history.

THERAPEUTIC MEASURES. Treatment depends on the degree of symptoms. In the most severe cases, epinephrine may be given to quickly resolve the urticaria. Corticosteroids may be given orally, topically, or IV. Antihistamines and histamine (H2) blockers may aid in resolution by blocking the release of histamine. Patients suffering with the chronic form of urticaria might require IgE monoclonal antibody therapy such as with omalizumab (Xolair). The use of acupuncture as an adjunctive measure is being studied.

ANGIOEDEMA

PATHOPHYSIOLOGY AND ETIOLOGY. There are two major classifications of angioedema, acquired and hereditary. Hereditary angioedema is considered rare and consists of three types; acquired angioedema, the more common form, consists of six types. The underlying physiologic factor in the hereditary and most of the acquired types of angioedema is a defective or deficient C1inhibitor (C1-INH). This deficiency leads to a buildup of bradykinin, which leads to the symptomology. Visit the U.S. Hereditary Angioedema Association at www.haea.org for more information.

SIGNS AND SYMPTOMS. Depending on the location and extentiveness of the edema, angioedema eruptions are usually nonpruritic and painless. Unlike the epidermal eruptions of urticaria, angioedema eruptions are of the dermal and subcutaneous layers of the skin. There may also be mucous membrane edema. The eruptions usually last longer than with urticaria.

DIAGNOSTIC TESTS. A comprehensive history and physical examination confirm the diagnosis. Skin testing may be performed to determine the specific antigen.
Therapeutic Measures. The most basic treatment involves avoiding the antigen. Symptoms may be relieved with antihistamines and corticosteroids. For long-term treatment, immunotherapy for allergen desensitization may be indicated.

Treatment modalities for acute symptoms include a number of newer Food and Drug Administration–approved medications:

- To build up the patient’s C1-INH, there is Cinryze, a purified C1-INH and ecallantide (Berinert) a C1-esterase inhibitor, which prevents the breakdown of any C1 inhibitor present.
- Kalbitor, a brand of plasma kallikrein inhibitor helps symptoms.
- Icatibant (Firazyr), a selective bradykinin B2 receptor antagonist, helps symptoms.
- Infusion of fresh frozen plasma reverses the angioedema symptoms associated with angiotensin-converting enzyme inhibitor–induced angioedema, which tends to be resistant to standard treatments.
- Androgens, antifibrinolytics, and immunosuppressive therapy are useful in the long-term treatment of some of the acquired types of angioedema.

Nursing Process for the Patient With a Type I Hypersensitivity Disorder

Data Collection. Gather information about the patient’s signs and symptoms. Immediately report any sudden dyspnea, shortness of breath, anxiety, restlessness, or chest or back pain. Identify any allergies the patient may have as well as signs and symptoms that occur with exposure to the allergen. Perform a thorough skin assessment, and carefully document any lesions or rashes. Note any changes in rashes or lesions. Perform a thorough skin assessment, and carefully document any lesions or rashes. Note any changes in rashes or lesions or signs of infection, such as redness, warmth, and drainage. Assess the patient’s knowledge of disease process, causes, treatment plan, and self-care. Note responses to treatments.

Nursing Diagnoses, Planning, and Implementation.

Impaired Gas Exchange Related to Laryngeal Edema

Expected Outcome: The patient will maintain clear lung fields and remain free of signs of respiratory distress at all times.

- Monitor respiratory rate, depth, and effort such as use of accessory muscles, nasal flaring, or abdominal breathing to identify problems early.
- Monitor the patient for restlessness, changes in mentation, level of consciousness, changes in voice, or dysphagia to identify problems and intervene early.
- Position the patient in a high-Fowler’s or semi-Fowler’s position to improve ventilation and decrease upper airway edema.

Anxiety Related to Dyspnea or Pruritus

Expected Outcome: The patient will state that anxiety is controlled.

- Stay with the patient and speak calmly to reduce fear or frustration.
- Teach patient to visualize the absence of anxiety, itching, or dyspnea to decrease anxiety.

- Provide family with the information needed to distinguish between anxiety or panic and a serious physiological problem so that they can make informed decisions regarding obtaining emergency medical care.

Risk for Impaired Skin Integrity Related to Effects of Allergic Reaction

Expected Outcome: The patient’s skin will remain intact.

- Assess and document skin and lesions to provide a basis for interventions and evaluation.
- Teach patient to keep fingernails short and clean to minimize the damage or risk for infection if scratching does occur.
- Teach patient to apply clean, white cotton clothing (socks, gloves/mittens, undershirt) over affected area, especially at bedtime, to minimize scratching while allowing for air movement with minimal irritation from dyes.
- Teach patient to use gentle rubbing or pressure instead of scratching to minimize the amount of skin trauma.

Ineffective Health Maintenance Related to Lack of Knowledge of Methods to Decrease Inflammation and Pruritus and Reduce Episodes of Inflammation

Expected Outcome: The patient or caregiver will state understanding and follow the mutually agreed-on plan of care.

- Assess patient’s knowledge of disease and its causes to provide a basis for teaching and evaluation.
- Assess patient’s values and beliefs regarding plan of care to ensure that it corresponds to patient’s ideals, thereby improving compliance.
- Assess barriers to patient’s ability to carry out plan of care and plan interventions to decrease barriers to improve the likelihood of patient implementing the plan of care.
- Discuss methods of avoiding the allergen with the patient, such as wearing a mask when mowing the lawn or working outdoors, having heating ducts cleaned, covering heat registers with filters, and frequent home vacuuming and dusting to promote an understanding of preventive methods and prevent allergen exposure and anaphylaxis.
- Teach patient to use medical identification for allergies so prompt medical attention can be given if the patient is unable to give information.
- Explain need to obtain a prescription for an epinephrine autoinjector, and teach patient how to use it if antigen is environmental (e.g., insect sting or foods; see Chapter 18).
- The teaching plan for atopic dermatitis includes signs and symptoms of infection, use of humidification during the winter months to prevent dryness, wearing cotton clothing to minimize irritation, and cool soaks to decrease pruritus.
- Teaching for urticaria includes stress management and relaxation techniques to relieve urticaria and to follow therapeutic regimen including prescribed medications and their correct usage to reduce symptoms.
- Document teaching and patient understanding.

Evaluation. If interventions have been effective, there will be no signs of respiratory distress, and lung fields will be
clear. The patient’s posture, facial expressions, gestures, and concentration will reflect no anxiety. The skin will remain intact. If there are lesions, they will be reduced and healing. The patient will express knowledge of disorder and treatment plan. The patient will verbalize no barriers to attaining treatment goals.

**Type II Hypersensitivity Reaction**

A type II hypersensitivity reaction involves the destruction of a cell or substance that has an antigen attached to its cell membrane, which is sensed by either immunoglobulin G (IgG) or immunoglobulin M (IgM) as being a foreign antigen (Fig. 19.2). When an antigen marker is sensed as foreign, an antibody attaches to the antigen on the cell membrane, causing lysis of the cell or accelerated phagocytosis (engulfing and ingestion). When a cell is foreign, such as a bacterium, this process is beneficial. However, sometimes antigens on the surface of a red blood cell (RBC) can be sensed as foreign for the different ABO blood types, which results in the RBC being destroyed.

**Hemolytic Transfusion Reaction**

**PATHOPHYSIOLOGY.** A hemolytic transfusion reaction is a type II hypersensitivity reaction in which incompatible surface antigens on RBCs are transfused. These antigens may be ABO or Rh incompatible. (ABO and Rh [Rhesus] are human blood group systems.) The recipient’s antibodies attach to the foreign antigens on the transfused RBCs, causing rapid lysis (destruction) of the RBC. The rapid RBC lysis results in a massive amount of cellular debris that blocks blood vessels throughout the body. This leads to ischemia and necrosis of tissue and organs and can be life threatening.

**ETIOLOGY.** Occasionally, antibodies form after a bacterial or viral infection. However, prior sensitization is usually from a previous blood transfusion or pregnancy. ABO and Rh blood type must be matched for transfusions. The ABO blood types are A, B, AB, and O (Fig. 19.3). People with blood type O are universal donors because they do not have A or B antigens. However, those with type O blood can receive only type O blood. People with type AB blood are universal recipients, because they do not make A or B antibodies. Those with blood types other than AB cannot receive AB blood because they have A or B antibodies.

Rh antigens are present in people who are Rh+. A person who is Rh+ has the D antigen, which is the strongest antigen of the 50 possible antigens. Rh antibodies are present in those who are Rh− after a sensitizing event. A person who is Rh− does not have the D antigen. Those who are Rh− can receive Rh− blood, but those who are Rh− cannot receive Rh+ blood because of the formation of antibodies to the Rh+ blood. If maternal and fetal blood Rh factors (RBC surface antigens) are different, the mother becomes sensitized by the fetal Rh type, which can

![Figure 19.2 Type II hypersensitivity.](image-url)

affect future fetuses. For example, an Rh0(D)-negative pregnant woman becomes sensitized by a Rh0(D)-positive fetus. As a result, the blood cells of future Rh0(D)-positive fetuses can be destroyed by maternal antibodies crossing the placenta.

**DIAGNOSTIC TESTS.** The direct Coombs’ test confirms this diagnosis. In the laboratory, a small amount of the patient’s RBCs is washed to remove any unattached antibodies. Antihuman globulin is added to see if agglutination (clumping) of the RBCs occurs. If agglutination occurs, an immune reaction such as a hemolytic transfusion reaction is taking place.

**THERAPEUTIC MEASURES.** To prevent production of anti-Rh0(D) antibodies, a Rh0(D) immune globulin (RhoGAM) injection is given to Rh0(D)-negative patients accidentally given Rh0(D)-positive blood or exposed to Rh0(D)-positive fetal blood by delivery, miscarriage, abortion, amniocentesis, or intra-abdominal trauma. When antibodies do not form, then a hemolytic reaction can be prevented.

If a reaction occurs, medications are given to treat the reaction such as those listed in Table 19.4.

**NURSING PROCESS FOR THE PATIENT EXPERIENCING A HEMOLYTIC TRANSFUSION REACTION.**

**Data Collection.** Prevention of hemolytic reactions is crucial. Following strict institutional guidelines for blood transfusion administration helps ensure the patient’s safety. After blood is released from the hospital blood bank, two nurses, designated per institutional policy, double-check specified data. At the bedside, transfusion guidelines include double-checking the patient’s name and identification number on the chart, unit of blood, and patient’s identification bracelet, as well as checking the patient’s blood type in the chart, on the unit of blood, and paperwork with the unit of blood.

Agency policy is followed for taking vital signs during a blood transfusion. Minimally, vital signs are taken before the start of the blood transfusion, 15 minutes into the transfusion, and when the transfusion is completed. It takes only a small amount of blood to trigger a hemolytic transfusion reaction, so it is critical to stay with the patient at the bedside during the first 15 minutes of any blood transfusion. This enables detection of a blood transfusion reaction early for quick action to minimize cell destruction and complications, including death.

If symptoms of a reaction are noted, the blood transfusion is immediately stopped, and agency policy for a suspected transfusion reaction is followed. A normal saline infusion with new tubing is started to keep the vein patent. The health care practitioner (HCP) and blood bank are immediately notified. A nurse remains with the patient for reassurance and monitoring of symptoms and vital signs. If a blood incompatibility is suspected, the unused blood and blood tubing are returned to the blood bank for testing. A series of blood and urine specimens are collected and sent to the laboratory for analysis. The HCP’s orders are followed to treat the patient’s symptoms.

**BE SAFE!**

Every unit of blood, even of the same blood type, is unique and can trigger a blood transfusion reaction. Careful monitoring with every transfusion is necessary.

### CRITICAL THINKING

**Blood Types**

1. Who is the universal ABO Rh recipient?
2. Who is the universal ABO Rh donor?
3. Can someone with an A Rh− blood type safely receive O Rh+ blood?

*Suggested answers are at the end of the chapter.*

### SIGNS AND SYMPTOMS.

A hemolytic transfusion reaction is usually accompanied by a rather sudden onset of low back (flank) or chest pain, hypotension, fever rising more than 1.8°F (1°C), chills, tachycardia, tachypnea, wheezing, dyspnea, urticaria, and anxiety (Table 19.3). The patient also may report a headache and nausea.

Nursing Diagnoses, Planning, and Implementation.

Fear related to serious threat to health status

**EXPECTED OUTCOME:** The patient will state reduced fear.

- Allow patients to express their concerns to allow inaccurate information to be corrected.
- Inform patients about procedures and treatments to reduce fear.
- Remain with patient and allow significant others to visit to offer emotional support.

Ineffective Tissue Perfusion, Cardiopulmonary and Peripheral, related to arterial/venous blood flow exchange problems

**EXPECTED OUTCOME:** The patient will have adequate tissue perfusion as evidenced by palpable peripheral pulses, urinary output of 30 mL per hour, and no respiratory distress.

- Assess and maintain airway, and provide oxygen to promote oxygenation.
- Assess for pain and provide pain relief measures to reduce pain.
- Monitor vital signs and intake and output to detect changes for prompt treatment.
- Position patient with head elevated if short of breath to aid breathing.

Ineffective Tissue Perfusion, Cardiopulmonary and Peripheral, related to arterial/venous blood flow exchange problems

**EXPECTED OUTCOME:** The patient will have adequate tissue perfusion as evidenced by palpable peripheral pulses, urinary output of 30 mL per hour, and no respiratory distress.

- Assess and maintain airway, and provide oxygen to promote oxygenation.
- Assess for pain and provide pain relief measures to reduce pain.
- Monitor vital signs and intake and output to detect changes for prompt treatment.
- Position patient with head elevated if short of breath to aid breathing.

Risk for Injury related to prolonged shock resulting in multiple organ failure, death

**EXPECTED OUTCOME:** The patient will remain free of injury at all times.

- Use two methods to identify patient before giving blood products to prevent incorrect identification and administration of blood product.
- Remain with patient during first 15 minutes of transfusion and then obtain vital signs to detect signs of reaction.
- Give medications such as epinephrine or steroids, as ordered, to support affected tissues and organs.
- Give diuretics as ordered to assist kidney excretion of cellular debris from reaction.

Deficient Knowledge related to lack of exposure to blood transfusions

**EXPECTED OUTCOME:** The patient will state understanding of blood transfusion options.

- Encourage patient to discuss autologous (self) blood donation option with HCP to avoid a transfusion reaction. This may be an option for patients having elective surgery.
- After a hemolytic transfusion reaction, explain to patients the importance of informing future health care providers...
about the reaction to ensure that specific blood tests are performed for less common antibodies if the patient is ever typed for a blood transfusion again.

**EVALUATION.** If interventions have been effective, the patient states reduced fear, has normal organ and tissue function, and reports understanding of blood transfusion options to prevent transfusion reactions.

**Type III Hypersensitivity Reaction**

A type III hypersensitivity reaction involves immune complexes formed by antigens and antibodies, usually of the IgG type (Fig. 19.4). The patient is sensitized with an initial exposure to the antigen, and a reaction occurs with a later exposure. The reaction is localized and evolves over several hours, with symptoms ranging from a red, edematous skin lesion to hemorrhage and necrosis. The process involves formation of antigen–antibody complexes in the blood vessels as the antigen is absorbed through the vessel wall. Neutrophils are attracted to the area and release enzymes that ultimately lead to blood vessel damage.

**Serum Sickness**

**PATHOPHYSIOLOGY AND ETIOLOGY.** Serum sickness is a type III hypersensitivity immune reaction in which antigen–antibody complexes form and lodge in small vessels, which leads to inflammation, tissue damage, and necrosis. Serum sickness occurs occasionally after administration of penicillin or sulfonamide.

**SIGNS AND SYMPTOMS.** The signs and symptoms usually occur 7 days to 3 weeks after the exposure. Most predominant is severe urticaria and angioedema. The patient may have a fever, malaise, muscle soreness, arthralgia, splenomegaly, and occasionally nausea, vomiting, and diarrhea. Lymphadenopathy may occur, especially in the lymph nodes closest to the antigen entry site.

**DIAGNOSTIC TESTS.** With serum sickness, there is often a slight elevation in the white blood cell (WBC) count, sedimentation rate, and C-reactive protein. IgG and IgM immunoglobulins increase substantially, while the complement assay decreases. Plasma cells are seen on the peripheral blood smear.

**THERAPEUTIC MEASURES.** Because serum sickness tends to be self-limiting within about 10 days, treatment is focused on symptoms. Antipyretics may be given for fever and analgesics and anti-inflammatories for arthralgia. Antihistamines and epinephrine may be given for urticaria and angioedema. If symptoms persist, corticosteroids may be ordered.

***FIGURE 19.4*** Type III hypersensitivity.
NURSING PROCESS FOR THE PATIENT WITH SERUM SICKNESS.

Data Collection. Symptoms are noted. Responses to prescribed medications are documented. The causative agent may be identified through the history-taking process and is important for the patient to determine to prevent a recurrence of the condition.

Nursing Diagnoses, Planning, and Implementation

Pain related to muscle and joint soreness

**EXPECTED OUTCOME**
- The patient will state pain is reduced to acceptable level within 30 minutes of report of pain.
- **Monitor pain using a pain rating scale of 0 to 10 to identify need for treatment.**
- **Provide analgesics as ordered to relieve symptoms.**

Risk for Deficient Fluid Volume related to fever and gastrointestinal fluid loss

**EXPECTED OUTCOME**
- The patient will maintain blood pressure, pulse, and urine output within normal limits.
- **Observe for signs of hypovolemia, such as restlessness, weakness, muscle cramps, headaches, inability to concentrate, irritability, and postural hypotension to detect deficiencies to report to the HCP.**
- **Monitor intake and output to detect imbalances.**
- **Provide antiemetics as ordered to relieve nausea.**
- **Encourage oral replacement therapy with hypotonic glucose-electrolyte solutions, such as sports replacement drinks or ginger ale, because they increase fluid absorption and correct deficient fluid volume.**
- **Maintain IV fluids at ordered rate to replace lost fluids, but avoid fluid overload.**

EVALUATION. Goals are met if the patient reports less pain and if vital signs and urine output are within normal limits.

Type IV Hypersensitivity Reaction

A type IV hypersensitivity reaction, also called a delayed reaction, occurs when a sensitized T lymphocyte comes in contact with the particular antigen to which it is sensitized (Fig. 19.5). The resulting necrosis is caused by the actions of macrophages and the various T lymphocytes involved in the cell-mediated immune response.

Contact Dermatitis

**PATHOPHYSIOLOGY.** When a substance or chemical comes in contact with the skin, it is absorbed and binds with special skin proteins called haptens. With the first contact, there is no reaction or symptoms, but within 7 to 10 days, T memory cells are formed. Therefore, on subsequent exposures, the T memory cells quickly become activated T cells, which secrete the chemicals that may cause symptoms.

**ETIOLOGY.** Poison ivy and poison oak are the most common irritants causing this reaction. Latex rubber also may cause contact dermatitis and can trigger type I anaphylactic reactions.

Latex Allergy. Latex allergy is a serious problem for those who work in health care. Anaphylactic reactions to latex can be fatal. Exposure to latex for those in health care has increased dramatically since the implementation of universal precautions and the use of latex gloves began in 1987. Many times, latex gloves are worn when they are not needed, which increases exposure to the latex protein. Latex-free gloves are available. For patients who are allergic to latex, special protocols are followed using latex-free equipment. For information about latex allergy, visit the American Academy of Allergy, Asthma, and Immunology at www.aaaai.org. Also visit the U.S. Food and Drug Administration at www.fda.gov.

**SIGNS AND SYMPTOMS.** Within a number of hours of exposure, the area of contact becomes red and pruritic, with fragile vesicles. Secondary infections may develop. (See earlier discussion of atopic dermatitis.)

**DIAGNOSTIC TESTS.** Diagnosis is made by assessment of the skin and lesions through biopsy, culture or patch testing, and a detailed patient history.

**THERAPEUTIC MEASURES.** Treatment consists of controlling symptoms. Oral or topical antihistamines and topical drying agents may be used. Topical corticosteroids may be used and are most effective if sparingly applied after a bath or shower.

If symptoms are severe, systemic corticosteroids may be prescribed. Tacrolimus (Protopic) and pimecrolimus (Abreva), which are classified as topical immunomodulators, may also be prescribed when other treatments fail.
NURSING PROCESS FOR THE PATIENT WITH CONTACT DERMATITIS.

Data Collection. Symptoms are assessed for planning of interventions. Identification of the causative agent is noted in the patient’s history. Patient recognition of the cause is important to prevent a recurrence of the condition. Special protocols are used for patients allergic to latex. Some facilities may prepare special latex-free kits containing common supplies nurses use to care for patients. Ensure that latex allergy protocols are followed if a patient has a latex allergy to prevent possible development of life-threatening anaphylaxis.

Nursing Diagnoses, Planning, and Implementation. See Nursing Care Plan for the Patient With Contact Dermatitis.

Transplant Rejection

PATHOPHYSIOLOGY AND ETIOLOGY. Any form of transplanted living tissue is sensed as foreign material by the immune system. This is why lifelong immunosuppression is needed to help prevent transplant rejection, which can occur at any time. Lymphocytes become sensitized during an induction phase immediately after the tissue is transplanted. If immunosuppression is not effective, the sensitized lymphocytes invade the transplanted tissue and destroy it via the release of chemicals and macrophage activity, resulting in varying degrees of transplant rejection.

SIGNS AND SYMPTOMS. Various signs and symptoms occur depending on the transplanted tissue or organ involved and the severity of the reaction (Table 19.5). Signs and symptoms reflect failure of the organ or tissue, such as renal failure for a rejected kidney.

COMPLICATIONS. A total failure and loss of the transplanted tissue or organ can occur, or the tissue or organ can be damaged from immunological reactions and not function at full capacity. The greatest cause of death following a transplant is infection. Immunosuppression therapy, which is needed to prevent tissue rejection after the transplant, is a major contributory factor for severe infection development. Because the immune system is suppressed, it is unable to effectively fight infections.

DIAGNOSTIC TESTS. Biopsy, scans, blood tests, arteriography, and ultrasonography are some tests that may be performed to aid in diagnosing a transplant rejection.

THERAPEUTIC MEASURES. Depending on the type of transplant, the body’s immunological system is prepared before surgery with medications, transfusions, or radiation to minimize the risk of rejection. After the transplant, lifelong immunosuppression is needed (although studies are ongoing in which the same or gan donor’s bone marrow is transplanted at the same time as the organ transplant such as a kidney to reduce or elimination the need for antirejection drugs). Improved specificity of immunosuppressants has reduced medication side effects while improving patient outcomes. If rejection occurs, medications may be used to attempt to reverse the rejection. Supportive care is provided based on the failing organ, such as hemodialysis if a kidney rejection occurs.

NURSING CARE. Nursing care depends greatly on the type of transplant performed. Initially, the patient is in an intensive care unit under close observation and support. Observing for signs of rejection is a priority throughout the patient’s hospitalization. Another consideration for nursing care is the psychological support of patient and family. Many patients wait a long time before a donor match is found. Once a matching donor is found, there is usually great elation. Yet if a donor’s death made the transplant possible, the patient and family may simultaneously feel a profound sadness for the donor’s family. Patients need time to verbalize feelings and understand that these feelings are normal and diminish with time. Also, the fear of transplant rejection is always present and must be discussed.

### NURSING CARE PLAN for the Patient With Contact Dermatitis

**Nursing Diagnosis:** Risk for Impaired Skin Integrity related to effects of allergic reaction and pruritus

**Expected Outcome:** The patient’s skin will remain intact.

**Evaluation of Outcome:** Is patient’s skin intact? If not intact, is skin healing? Does patient express a plan for preventing impaired skin integrity?

<table>
<thead>
<tr>
<th>Intervention</th>
<th>Identify and document skin and lesions. <strong>Rationale</strong> Provides a basis for intervention planning and evaluation of healing. <strong>Evaluation</strong> Are lesions present? Are lesions healing?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intervention</td>
<td>Teach patient to keep fingernails short and clean. <strong>Rationale</strong> Short, clean nails cause less damage or infection if scratching occurs. <strong>Evaluation</strong> Does skin remain intact despite scratching?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Teach patient to apply clean, white cotton clothing (socks, gloves/mittens, undershirt) over affected area, especially at bedtime. <strong>Rationale</strong> Cotton allows air movement. White cloth is less irritating than those with dyes. Scratching is decreased during sleep with the use of gloves/mittens or by covering affected area. <strong>Evaluation</strong> Are symptoms of skin irritation reduced?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Teach patient to use gentle rubbing or pressure instead of scratching. <strong>Rationale</strong> Use of gentle rubbing or pressure instead of scratching causes less skin trauma. <strong>Evaluation</strong> Does skin remain intact despite itchy sensation?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Explain that tepid baking soda baths, colloidal oatmeal baths (e.g., Aveeno), and cool washcloths or cool baths reduce itching. <strong>Rationale</strong> These items help dry the vesicle and minimize the pruritus. <strong>Evaluation</strong> Is itching reduced?</td>
</tr>
</tbody>
</table>

**Nursing Diagnosis:** Ineffective Health Maintenance related to lack of knowledge of methods to decrease inflammation and reduce episodes of inflammation

**Expected Outcome:** The patient or caregiver will follow the mutually agreed-on plan of care.

**Evaluation of Outcome:** Can patient express knowledge of etiology, signs and symptoms, and treatment plan? Does patient discuss any emotional, social, financial, or material blocks to attaining treatment goals?

<table>
<thead>
<tr>
<th>Intervention</th>
<th>Identify patient’s knowledge of disease and causes. <strong>Rationale</strong> Provides a basis for the teaching plan. <strong>Evaluation</strong> Does patient state baseline knowledge?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intervention</td>
<td>Ask patient’s values and beliefs regarding plan of care. <strong>Rationale</strong> Patients are more compliant if their belief system fits into plan of care. <strong>Evaluation</strong> Does patient’s belief system work with plan of care?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Identify barriers to patient’s ability to carry out plan of care and plan interventions to decrease barriers. <strong>Rationale</strong> Barriers can prevent patient from carrying out plan of care. <strong>Evaluation</strong> Are barriers identified? Are solutions to barriers planned?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Teach patient to wear medical alert identification for allergen. <strong>Rationale</strong> With allergen identification, prompt medical care can be given in case patient is unable to give information. <strong>Evaluation</strong> Does patient agree to use allergen identification?</td>
</tr>
<tr>
<td>Intervention</td>
<td>Discuss methods of avoiding allergen with patient. <strong>Rationale</strong> Understanding prevention methods can help prevent allergen exposure. <strong>Evaluation</strong> Can patient state methods to help prevent allergen exposure?</td>
</tr>
</tbody>
</table>

*Continued*
UNIT FOUR  Understanding the Immune System

NURSING CARE PLAN for the Patient With Contact Dermatitis—cont’d

**Intervention** Teach patient to wash with a brown soap (e.g., Fels-Naptha) or, if unavailable, any soap when contact with the offending agent is suspected. **Rationale** This removes offending agent. **Evaluation** Does patient state understanding of need to wash off agent with exposure?

**Intervention** Teach patient not to scratch skin. **Rationale** Scratching can spread the dermatitis, as well as cause infection. **Evaluation** Does patient avoid scratching?

**Education.** Rejection can take place weeks, months, or years after a transplant (with decreasing risk). The patient and family need to be educated about specific signs and symptoms of rejection. Also, because infection is a major complication of long-term immunosuppressant medications, the patient and family need to know signs and symptoms of infection and when to notify the HCP of problems. Steroid use may mask the symptoms of infection, so small indicators such as a low-grade fever should be reported promptly. Education regarding prescribed medications is a must because the long-term success of a transplant depends on compliance with immunosuppressant therapy. Avoidance of people with colds or infections is also important to reduce the immunosuppressed patient’s risk of infection.

**AUTOIMMUNE DISORDERS**

In autoimmune disorders, the immune system no longer recognizes the body’s normal cells as self. Instead, antigens on these normal body cells are recognized as foreign material, and the body launches an immune response to destroy them.

A number of factors either cause or influence this breakdown of self-recognition, including viral infections, drugs, and cross-reactive antibodies. Some microbes stimulate production of antibodies but are so closely related to normal cell antigens that the antibodies also attack some normal cells. Hormones also may influence this breakdown of self-recognition.

Some autoimmune disorders are discussed next, whereas others are discussed in chapters related to the body system most affected. Table 19.6 lists additional autoimmune disorders and the chapters in which they are discussed.

</tbody>
</table>

**Pernicious Anemia**

**PATHOPHYSIOLOGY.** Antibodies that destroy gastric parietal cells lead to decreased production of intrinsic factor. Other intrinsic factor antibodies (type I and type II) alter the binding sites, which ultimately decreases the ability of intrinsic factor to assist in the absorption of vitamin B₁₂ in the ileum. Intrinsic factor plays a role in vitamin B₁₂ absorption in the small bowel, so a vitamin B₁₂ deficiency may result, causing decreased production of RBCs. Intrinsic factor is involved in most vitamin B₁₂ absorption, but evidence has demonstrated that there is a route independent of intrinsic factor for some absorption of vitamin B₁₂. This has important treatment implications.

**ETIOLOGY.** There tends to be a familial tendency toward the autoimmune form of pernicious anemia. Causes of the acquired form of pernicious anemia (non–immune-related) include any type of gastric or small-bowel resections coupled with no or inadequate vitamin B₁₂ or intrinsic factor replacement.

**SIGNS AND SYMPTOMS.** The patient experiences increasing weakness, loss of appetite, glossitis (inflammation or infection of the tongue), and pallor. Irritability, confusion, and numbness or tingling in the extremities (peripheral neuropathy) occur because the nervous system is affected.

**DIAGNOSTIC TESTS.** On microscopic examination of the patient’s RBCs, macrocytic (enlarged cells) anemia is diagnosed. Macrocytic anemia and low vitamin B₁₂ levels are indicators of pernicious anemia and folic acid deficiency. To determine if the diagnosis is pernicious anemia, intrinsic factor antibodies and parietal cell antibodies can be tested. Methylmalonic acid levels (when vitamin B₁₂ low), and homocysteine, will be elevated, whereas serum cobalamin will be decreased.

A Schilling test can be done but is used less today than in the past because it is a complicated test. For the Schilling test, radioactive vitamin B₁₂ is administered to the patient. The patient’s urine is then collected for 24 hours (48 hours for patients with renal disease), and the amount of radioactive vitamin B₁₂ excreted in the urine is measured. If intrinsic factor is decreased, gastric absorption of vitamin B₁₂ is also decreased, so that more vitamin B₁₂ is excreted in the urine. Gastric secretion analysis is done to measure levels of hydrochloric acid (HCl) because low or absent HCl may indicate pernicious anemia.

Further studies such as radioimmunoassay (RIA) or enzyme-linked immunosorbent assay (ELISA) may be performed to...
confirm an autoimmune etiology and specify which antibody is present, type I or type II.

**THERAPEUTIC MEASURES.** Corticosteroids may correct the problem if it is immunologically caused. Otherwise, vitamin $B_12$ therapy is needed, usually for life.

**NURSING CARE.** Vitamin $B_12$ is administered as ordered. Care related to fatigue and safety are important. Ambulation, frequent rest periods, and providing assistance with activities of daily living (ADLs) as indicated by the patient’s activity tolerance are helpful for the patient with anemia.

**Education.** The patient and family need education regarding oral or parenteral medication therapy. If vitamin $B_12$ injections are prescribed, the patient must understand that this is a lifelong need to prevent the return of symptoms. Patients should not miss injections, periodic vitamin $B_12$ testing, or follow-up appointments.

**Idiopathic Autoimmune Hemolytic Anemia**

**PATHOPHYSIOLOGY.** In this disorder, autoantibodies, for no known reason, are produced that attach to RBCs and cause them to either lyse or agglutinate (clump). When lysis occurs, fragments of the destroyed RBCs circulate in the blood. If agglutination occurs, clumps in the small blood vessels are followed by tissue ischemia.

**SIGNS AND SYMPTOMS.** Clinical manifestations vary from mild fatigue and pallor to severe hypotension, dyspnea, pallor, headaches, and jaundice. Problems concentrating and thinking frequently occur.

**DIAGNOSTIC TESTS.** The RBC count, hemoglobin (Hgb), and hematocrit (Hct) are low, and microscopic examination reveals fragmented RBCs. Lactate dehydrogenase (LDH) and serum bilirubin levels are elevated because of RBC destruction and tissue ischemia.

**THERAPEUTIC MEASURES.** Supportive measures such as supplemental oxygen may be started. Folic acid may be prescribed to increase production of RBCs. IV immunoglobulin, immunosuppressant medications, and corticosteroids may be useful in obtaining remission. In more severe cases, blood transfusions and erythrocytapheresis (a process in which abnormal RBCs are removed and replaced with normal RBCs) may be instituted. For severe cases a splenectomy may be performed in an attempt to stop the destruction of RBCs.

**NURSING CARE.** The patient’s signs and symptoms should be monitored and reported as needed. Frequent rest periods should be planned into the patient’s daily routine to prevent fatigue. Blood products are administered as ordered to replace RBCs.

**Education.** The patient and family are instructed on the medical regimen, and their understanding is verified.

**Hashimoto’s Thyroiditis**

**PATHOPHYSIOLOGY.** Autoantibodies for thyroid-stimulating hormone (TSH) form in Hashimoto thyroiditis. However, instead of inactivating TSH, the autoantibodies bind with hormone receptors on the thyroid gland and stimulate the thyroid gland to secrete thyroid hormones. The thyroid gland enlarges as a result of this overstimulation (hyperthyroidism). It becomes infiltrated with lymphocytes and phagocytes, causing inflammation and further enlargement. Then different autoantibodies appear that destroy thyroid cells, which slows secretion activity, causing hypothyroidism.

**ETIOLOGY.** The exact cause is unknown, although it occurs in females eight times more often than in males. It is also more common in people aged 30 to 50 years and patients with Down syndrome and Turner syndrome.

**SIGNS AND SYMPTOMS.** Initial signs and symptoms are those of hyperthyroidism, such as restlessness, tremors, chest pain, increased appetite, diarrhea, moist skin, heat intolerance, and weight loss. These manifestations may go unrecognized and progress quickly into hypothyroidism. At this point, an enlarged thyroid gland (goiter) may be seen. Signs and symptoms may include fatigue, bradycardia, hypotension, dyspnea, anorexia, constipation, dry skin, weight gain, sensitivity to cold, facial puffiness, and a slowing of mental processes.

**DIAGNOSTIC TESTS.** Immunofluorescent assay, a test that detects antigens on cells using an antibody with a fluorescent tag, detects antithyroid antibodies. Serum TSH levels are elevated, whereas triiodothyronine ($T_3$) and thyroxine ($T_4$) levels are low. A thyroid scan is also done.

**THERAPEUTIC MEASURES.** Thyroid hormone replacement therapy of thyroxine is the primary means of treatment. Lifelong thyroid hormone therapy is needed.

**NURSING CARE.** If the patient has a goiter, a soft diet may be needed for comfort. Frequent rest periods may be needed, as well as slowly increasing patient activity. Antiembolic stockings may help prevent venous stasis during the low-energy, decreased-activity phase. Daily weights and monitoring intake and output when cardiac status is compromised are important to detect abnormalities such as fluid retention. Because weight gain and facial puffiness alter patients’ self-image, patients need an opportunity to verbalize their feelings to help them adjust to this disease process.

**Education.** Patients taking thyroid hormone replacement therapy should avoid foods high in iodine. The diet should also consist of large amounts of fiber to combat constipation. During the hyperthyroidism phase, a diet high in protein and carbohydrates encourages weight gain. Education regarding prescribed medications is also needed. Cholestyramine, ferrous sulfate, sucralfate, iron-containing multivitamins, calcium carbonate and all other antacids interfere with the absorption of levothyroxine from the gastrointestinal tract. Therefore, levothyroxine should not be taken within a minimum of 4-hour period from these medications.

**Lupus Erythematosus**

There are four types of lupus. Neonatal is the rarest form and is passed on from a mother who has lupus to her fetus.
Drug-induced lupus erythematosus (DILE) affects approximately 10% of total lupus patients and rarely affects major organs. Research has identified about 80 prescription medications that have caused DILE (Box 19-1). A small percentage of lupus patients have the type that affects only the skin, a condition called discoid lupus erythematosus (DLE). This form is not life threatening and does not affect any internal organs. Most patients with lupus have the systemic type, which can be life threatening because it is a progressive, systemic inflammatory disease that can cause major body organ and system failure. Although this definition seems similar to the definition of rheumatoid arthritis, one distinct difference exists. Patients with systemic lupus erythematosus (SLE) typically have more body organ involvement earlier in their disease than patients with rheumatoid arthritis.

**PATHOPHYSIOLOGY.** SLE is an autoimmune disease characterized by spontaneous remissions and exacerbations. In SLE, the body develops abnormal antibodies (antinuclear antibodies [ANAs]) against its own tissue, leading to the formation of immune complexes. These in turn activate the complement system, resulting in negative autoimmune effects on the patient’s healthy connective tissue. Many of the manifestations result from recurring injuries to the patient’s vascular system. The resulting immune complexes lodge in the blood and organs, leading to inflammation, damage, and possibly death.

**ETIOLOGY.** The cause of SLE is unknown, but the disorder tends to occur in families. Identified chromosomal markers indicate a genetic link. Environmental factors may also play a critical role in the development of SLE. Infections, high stress levels, various hormones and drugs (especially antibiotics such as sulfa and penicillin), and ultraviolet light have all been linked to triggering SLE. Exacerbation of symptoms, also called a “flare,” often occurs before the start of menstruation and during pregnancy, demonstrating the link hormones may have in triggering SLE. See Box 19-2 for a list of flare triggers.

African American, Hispanics, Native Americans, and Asians are two to three times more likely to develop SLE than others. Lupus most often affects women between ages 15 and 40 at a rate of 9 times more often than for men. Women represent 90% of all SLE cases.

With improved therapy, the mortality rate for patients with SLE has improved greatly during the past 30 years. The leading causes of death are kidney failure, heart failure, and central nervous system involvement.

**SIGNS AND SYMPTOMS.** Clinical manifestations vary from mild to severe (Table 19.7). The classic feature of lupus is the characteristic reddened butterfly rash found over the bridge.

| Fatigue | |
| Ineffective Health Maintenance | |
of the nose that extends to both cheeks, although less than half of patients develop the rash (Fig. 19.6). The rash is typically flat, not painful or pruritic and is photosensitive, worsening when exposed to ultraviolet light. Instead of the butterfly rash, some patients have discoid (coinlike) skin lesions on other parts of the body.

**DIAGNOSTIC TESTS.** Skin lesions can be biopsied and examined microscopically for signs of inflammation. Other tests include the erythrocyte sedimentation rate (ESR; to detect systemic inflammation) and ANA titers (to detect the presence of abnormal antibodies). There are also two subtypes of ANA: anti-ds DNA and anti-sm antibodies, which are found only in patients with SLE and can be useful in confirming a diagnosis of SLE. A blood test involving serine/arginine-rich (SR) proteins also may aid in diagnosis of SLE. Patients with SLE make antibodies against SR proteins (which are important in cell division). Seventy percent of SLE patients react positively to these anti-SR antibodies. Although no laboratory test confirms a diagnosis of SLE, the results of immunological tests may support the diagnosis.

**THERAPEUTIC MEASURES.** Treatment of SLE focuses on decreasing inflammation and preventing life-threatening organ damage (Table 19.8). The human monoclonal antibody belimumab (Benlysta) is the only medication directed at one of the

underlying processes of SLE, overstimulated B-lymphocytes. This medication decreases the activity of these cells, which in turn decreases the production of auto-antibodies. Many of the drugs used for SLE have serious side effects, and patients receiving them are carefully monitored.

Research is ongoing regarding the possible cause of SLE. Researchers have found more than 25 genes that are associated with or that, in combination, increase the risk for the development of lupus. These genetic discoveries are enabling researchers to develop new methods of therapy, including gene therapy.

**NURSING CARE.** Prevention of exacerbations (flares) is important, and therefore taking preventive measures is suggested. Minimizing exposure to the sun and artificial ultraviolet light by wearing protective clothing and 70 SPF sunscreens will help those patients who are photosensitive. Fatigue during activities of daily living can be minimized through the use of a daily personal schedule. Additionally, the patient needs a minimum of 8 hours of sleep per night with naps as needed to combat fatigue. Because most patients with SLE develop transitory arthralgia (joint pain), maintaining fitness and joint range of motion through a regular fitness program while decreasing activity during flares is vital. Warm baths may help with morning stiffness, and application of heat and cold compresses, splints, assistive devices, and physical therapy may help soreness. Eating a well-balanced diet will also influence the level of fatigue and the corticosteroid-induced weight gain, which also can affect joint soreness. Additionally, it is recommended that patients keep immunizations up to date.

Finally, but most importantly, the patient’s psychological state and support systems need to be addressed. The period from the onset of symptoms to the diagnosing of lupus is usually costly in terms of time, money, and emotions. Patients may face anger, frustration, and confusion before the diagnosis. For many, there is a sense of relief at diagnosis that may quickly be replaced with feelings of anger, fear, depression, or grief. It is here when empathy, support, hope, and, most importantly, education for the patient, family, and significant others are vital for acquiring successful long-term coping skills. In addition, local support groups and educational and self-management programs available through the Lupus Foundation of America (www.lupus.org) can provide patients with avenues for attaining more specific knowledge and skills for coping and taking control of their lives.

**Education.** Explain the signs of bleeding and of cardiac and vascular problems, such as myocardial infarction and thrombophlebitis. Encourage the use of a medical alert bracelet. Provide smoking cessation information to patients who smoke. Because renal disease is a major complication of SLE, patients must learn the signs of impending problems that need to be relayed to the HCP immediately. These are such findings as facial puffiness and “foamy” urine or “coke-colored” urine indicative of proteinuria and hematuria, respectively. Explain that regular ophthalmic examinations are needed for early detection and treatment of the complications that antimalarial drugs and corticosteroids can produce, such as retinal bleeding, glaucoma, and cataracts.

- May have serious side effects; careful monitoring is needed.

**CRITICAL THINKING**

**Mr. Ellis**

Mr. Ellis is suffering from a flare of SLE. The HCP has ordered intramuscular Solu-Cortef 80 mg to be given every 8 hours. Solu-Cortef 125 mg per 2 mL is available. How many milliliters will the nurse administer per dose?  

Suggested answers are at the end of the chapter.
Ankylosing Spondylitis

PATHOPHYSIOLOGY. Ankylosing spondylitis, also called rheumatoid spondylitis, is a chronic progressive inflammatory disease primarily of the spine and sacroiliac area. It can also affect the large limb joints. The inflammatory process begins in the lower region of the back and progresses upward. A specific histocompatibility antigen (antigen that identifies self), human leukocyte antigen (HLA) B27, is formed that stimulates an immune response. It can result in complete fusion of the spine, causing complete rigidity in the spine, a condition known as “bamboo spine.”

ETIOLOGY. There is strong evidence of a familial tendency, but no other specific causes are known. Ankylosing spondylitis tends to afflict men more than women and is usually diagnosed at ages 18 to 30.

SIGNS AND SYMPTOMS. Ankylosing spondylitis causes an insidious onset of lower back stiffness and pain, which is worse in the morning. As the disease progresses, the pain worsens and there are spasms of the back muscles. The normal curvature of the lower back (lordosis) flattens, and the curvature of the upper back increases (kyphosis). Patients may also experience fatigue, anorexia, and weight loss.

DIAGNOSTIC TESTS. Findings such as a positive family history, a positive HLA-B27 blood test, negative Rh, and radiographs of the joints showing spinal changes and fusion (although these changes are a late finding) confirm a diagnosis of ankylosing spondylitis. There are no specific immunological tests to diagnose ankylosing spondylitis.

THERAPEUTIC MEASURES. Because there is no cure for ankylosing spondylitis, treatment consists of measures to minimize the symptoms. Analgesics and muscle relaxants for pain relief, anti-inflammatory agents to decrease joint inflammation, and physical therapy to maintain muscle strength and joint range of motion are used. Biological agents such as anti-tumor necrosis factor (TNF)-α, including etanercept (Enbrel), infliximab (Remicade), and adalimumab (Humira), have shown promising results in changing the disease progression. Surgery can be done to replace fused joints. For kyphosis, cervical or lumbar osteotomy can be performed. Physiotherapy and exercise can be beneficial in managing symptoms.

Klebsiella bacterium, which is found naturally in the gut but is found in high levels in the feces of patients with ankylosing spondylitis, may be a trigger for the disease. This bacterium requires starch to grow, so it’s thought that reducing starch in the diet might reduce symptoms. Visit the Spondylitis Association of America at www.spondylitis.org/main.aspx.

NURSING CARE. Nursing care focuses on patient education and administration and evaluation of prescribed medications (Box 19-3). Pain management, rest periods, assistance with ADLs, and exercise promotion are provided.

Box 19-3 Patient Education

Ankylosing Spondylitis

Help reduce pain and stiffness by:
- Providing disease information
- Explaining proper posture and range-of-motion exercises
- Teaching to change positions frequently
- Urging patients to sleep on a mattress that is firm without a pillow

CRITICAL THINKING

Mr. Beck

Mr. Beck, a truck driver who was recently diagnosed with ankylosing spondylitis, verbalizes concern about how this diagnosis will affect his ability to work.

1. How would the LPN/LVN answer his questions?
   a. “What is happening to me?”
   b. “Will I have to quit my job driving an interstate truck?”
   c. “Am I eventually going to have really bad pain?”
   d. “Am I eventually going to be dependent on someone?”

2. Mr. Beck plans to continue driving his truck and therefore has a need upon discharge for specific interventions that will help him maintain his independence. What will the nurse say to Mr. Beck on discharge about why each of the following instructions is important for him to follow?
   a. Perform range-of-motion exercises daily.
   b. Do not stay in one position too long. Stop and walk around often.
   c. Sleep on a firm mattress without a pillow.
   d. Maintain good posture, even when driving the truck.

Suggested answers are at the end of the chapter.

IMMUNE DEFICIENCIES

Immune deficiencies occur when one or more components of the immune system are either completely absent or deficient in quantities sufficient to elicit or sustain an adequate immune response to combat an infectious agent.

Hypogammaglobulinemia

PATHOPHYSIOLOGY AND ETIOLOGY. This condition is either a hereditary congenital disorder or acquired after
childhood from unknown causes. It is characterized by the absence or deficiency of one or more of the five classes of immunoglobulins (IgG, IgM, IgA, IgD, and IgE) from defective B-cell function. The lack of normal function of these antibodies makes the patient prone to infections. The congenital form of this disorder affects males. Patients usually have a normal life span.

**SIGNS AND SYMPTOMS.** The infant is usually asymptomatic until 6 months of age, when the maternal immunoglobulins are gone. At this time, the infant begins having many recurrent infections, especially from *Staphylococcus* and *Streptococcus* organisms.

**DIAGNOSIS.** Until an infant is 9 months old, diagnosis is extremely difficult. At 9 months of age, immunoelectrophoresis, which measures the level of each immunoglobulin, can be performed.

**THERAPEUTIC MEASURES.** Treatment is aimed at minimizing infections while increasing immune system function through subcutaneous injections or IV infusions of immunoglobulin. Immunoglobulin mainly contains IgG, so fresh frozen plasma is given to replace IgM. IgA cannot be replaced, increasing the risk for frequent pulmonary infections. Gene therapy has been shown to be successful in stabilizing infant immune systems with severe combined immunodeficiency but less effective with older patients.

**NURSING CARE.** The infant is monitored for infections. Any break in the skin must be cleansed immediately and monitored for infection development. Genetic counseling may be recommended for parents.

**Education.** The family is educated about signs and symptoms of a variety of infections and the importance in seeking medical help immediately. They are taught that the infant should not be in crowds and that good nutrition, hydration, and hygiene are important in preventing infections.

---

**Atopic Dermatitis**

- Instruct patients with atopic dermatitis to use a skin moisturizer daily to help prevent dryness, which can lead to the complications of eczema. Avoid baby lotions or any lotion that contains perfumes, which can irritate the skin, and alcohol products, which can further dry the skin.
- Use of regular soaps can be drying to the skin. Urge the patient and family to use only soaps labeled for sensitive skin.
- Assist the patient with choosing an oatmeal bath product that can be helpful in relieving skin dryness.
- Use an ice pack on the irritated area to help relieve the itching of atopic dermatitis.
- Monitor for a rash, especially around the torso and abdomen. If rash develops, consider the laundry soap being used and encourage a mild soap, such as one of those used to wash baby clothes (e.g., Dreft).

**Latex Allergy**

- Always have latex-free gloves available.
- Use a latex-free silicone urinary catheter.

**Transplants**

- Teach patients who have had a transplant and are taking immune-suppressing medications to avoid those who are ill with colds or flu and public places such as stores to help prevent infection. If they do go out, suggest they wear a surgical mask to help prevent exposure to illness.
- Teach patients to take medications as prescribed especially immunosuppressant medications.

---

**SUGGESTED ANSWERS TO CRITICAL THINKING**

- **Mrs. Barnes**
  1. Mrs. Barnes is most likely having an anaphylactic reaction to the bee stings with accompanying urticaria or even angioedema.
  2. Further assessment might include identification of any previous allergies to foods, medications, and environmental stimuli and what reactions occur with any allergies. Thorough respiratory assessment is needed, noting any adventitious sounds, particularly wheezing. Note any dysphagia or changes in her voice.
  3. Therapeutic measures to implement include monitoring vital signs, staying with the patient, using semi-Fowler’s to high-Fowler’s position, giving oxygen at 2 to 3 L per minute, and ensuring a patient IV access. Notify the registered nurse (RN) and/or HCP right away. Anticipate administration of antihistamines, epinephrine, and fluids.
  4. HCP, RN, respiratory therapist

- **Blood Types**
  1. AB Rh⁺.
  2. O Rh⁻.
  3. No, they can safely receive only A Rh⁻ or O Rh⁻ blood.

- **Mr. Ellis**
  1.28 mL per dose.

Continued
360  UNIT FOUR  Understanding the Immune System

SUGGESTED ANSWERS TO—cont’d

Mr. Beck
1. a. “Human leukocyte antigen B27 is formed, stimulating a chronic immune (inflammatory) response specifically in the spine, sacroiliac area, and large peripheral joints. This leads to thickening of the joints, joint pain, and stiffness.”
   b. “No, you shouldn’t have to quit your job, but you may need to alter the way you drive your truck.”
   c. “No, you may not eventually be in severe pain, with use of medications and exercise.”
   d. “No, this disease may not affect your independence, with proper treatment and rehabilitation.”
2. a. “Range-of-motion exercises will help maintain joint mobility and a full range of motion and prevent contractures from forming.”
   b. “Again, this frequent movement prevents stiffness and joint pain and contractures of joints.”
   c. “Sleeping on a firm mattress without a pillow keeps the spine in correct alignment, which in turn helps prevent progressive changes in spine alignment (kyphosis, scoliosis) that affect various major body systems (respiratory, etc.).”
   d. “Again, good posture will aid in preventing bone deformities.”

REVIEW QUESTIONS

1. A patient asks the nurse how an allergy can develop to a medication that has been taken before without problems. Which of the following is the most appropriate for the nurse to respond?
   1. “It probably is due to your age, because as we age, the body becomes more sensitive to environmental stimuli, which leads to hypersensitivities.”
   2. “What have you eaten in the last 24 hours? Most medications are altered by food, thereby producing different effects in the body.”
   3. “Viral illnesses and exposure to various chemicals and environmental substances can alter the immune system and its response to previously benign stimuli.”
   4. “Patients who have autoimmune disorders such as lupus or arthritis tend to develop sensitivities to common medications.”

2. The nurse is caring for a patient who asks what ankylosing spondylitis is. Which of the following responses from the nurse is appropriate?
   1. Chronic progressive inflammatory disease of large limb joints
   2. Autoantibodies that lyse RBCs
   3. Formation of antigen–antibody complexes leading to inflammation
   4. Production of IgE antibodies

3. The nurse is collecting data on a patient with suspected pernicious anemia. Which of these signs or symptoms would the nurse expect to find for this patient?
   1. Glossitis
   2. Itching
   3. Kyphosis
   4. Lower back spasms

4. The nurse is caring for a patient who is to have a Schilling test. What action would the nurse take for this test?
   1. Maintain on bedrest.
   2. Monitor vital signs.
   3. Collect 24-hour urine specimen.
   4. Maintain pressure dressing.

5. The nurse is caring for a patient with allergic rhinitis. Which of the following interventions should the nurse anticipate will be included in the treatment plan for this patient? Select all that apply.
   1. Antihistamines
   2. Avoiding environmental stimuli
   3. Immunotherapy
   4. Steroids
   5. Anticholinergics
   6. Decongestants

6. The nurse is collecting data from a patient with contact dermatitis. What data are essential for the nurse to obtain?
   1. Date of gastric surgery
   2. Appearance of skin lesions
   3. Weight gain
   4. Appetite

7. A patient is admitted with an autoimmune disease and asks the nurse what autoimmune means. Which of the following responses by the nurse would be appropriate?
   1. “Immune cells produce too many antibodies.”
   2. “Immune cells grow and multiply too rapidly.”
   3. “Immune cells are not produced in sufficient amounts.”
   4. “Immune cells are unable to distinguish between ‘self’ and ‘not self.’”
8. A patient who has an allergy to penicillin is receiving cefazolin (Ancef) intravenously. Fifteen minutes after the cefazolin is started, the patient reports an uneasy feeling, as well as feeling very warm. Which actions would the nurse take now? \textbf{Select all that apply.}
1. Offer the patient ice water.
2. Discontinue the IV.
3. Stay with the patient.
4. Turn off the IVPB (IV piggyback).
5. Call for assistance.
6. Monitor vital signs.

9. A patient who has been diagnosed with SLE is being discharged. The patient reports leaving on a 3-week tour of the Grand Canyon and going whitewater rafting in 1 week. Which of the following patient statements conveys the patient’s understanding of the plan of care?
1. “As long as I wear sunscreen, I’ll be fine in the sun.”
2. “I’ll wear clothing on all exposed skin and use sunscreen.”
3. “If I develop a rash, I should avoid the sun.”
4. “I should avoid the sun in the morning.”

\textbf{Answers can be found in Appendix C.}

\textbf{Reference}
Nursing Care of Patients With HIV Disease and AIDS

PATRICE WADE

LEARNING OUTCOMES

1. Define human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS).
2. Explain how HIV is transmitted.
3. List how HIV is diagnosed.
4. Describe the prognosis for HIV and acquired immunodeficiency syndrome (AIDS).
5. Develop a teaching plan for prevention of an HIV infection.
6. Identify prevention measures used to decrease infection and opportunistic diseases for patients with HIV.
7. Develop a teaching plan for a patient with HIV receiving antiretroviral therapy.
Acquired immunodeficiency syndrome (AIDS) is the late phase of a chronic immune function disorder caused by infection with the human immunodeficiency virus (HIV). AIDS can develop after a long period of HIV infection and can eventually be fatal, if left untreated. The Centers for Disease Control and Prevention (CDC) specifies the criteria for determining when HIV infection has developed into AIDS (Box 20-1).

**Box 20-1 CDC AIDS-Defining Conditions**

CD4+ T-lymphocyte count below 200/mm³, or a CD4+ T-lymphocyte percentage under 14 of total lymphocytes, or the presence of one of the following specified clinical conditions:

- Candidiasis of bronchi, trachea, or lung
- Candidiasis, esophageal
- Cervical cancer, invasive
- Coccidioidomycosis, disseminated or extrapulmonary
- Cryptococcosis, extrapulmonary
- Cryptosporidiosis, chronic intestinal (greater than 1-month duration)
- Cytomegalovirus (CMV) disease (not including liver, spleen, or nodes)
- CMV retinitis with loss of vision
- Encephalopathy, HIV related
- Herpes simplex, chronic ulcers (>1 month’s duration) or bronchitis, pneumonitis, or esophagitis (onset at age >1 month)
- Histoplasmosis, disseminated or extrapulmonary
- Isosporiasis, chronic intestinal (>1-month’s duration)
- Kaposi’s sarcoma
- Lymphoid interstitial pneumonia or pulmonary lymphoid hyperplasia complex
- Lymphoma, Burkitt
- Lymphoma, immunoblastic
- Lymphoma of the brain, primary
- Mycobacterium avium intracellulare complex or Mycobacterium kansasii, disseminated or extrapulmonary
- Mycobacterium tuberculosis, any site (pulmonary or extrapulmonary)
- Mycobacterium, other species or unidentified species, disseminated or extrapulmonary
- Pneumocystis jiroveci pneumonia
- Pneumonia, recurrent
- Progressive multifocal leukoencephalopathy
- Salmonella septicemia, recurrent
- Toxoplasmosis of brain
- Wasting syndrome

Not all HIV-infected people develop AIDS, largely because current treatments help to improve immune function and reduce the risk of opportunistic infections, which can be life threatening in these patients. The first antiretroviral (ARV) drug was introduced in 1987 and highly active antiretroviral therapy (HAART) began in 1996; both greatly reduced the death rate from AIDS. As a result, the number of people living today with HIV/AIDS is at its highest level ever (Fig. 20.1).

**LEARNING TIP**

HIV disease is no longer characterized as a life-ending illness. With ARV therapy, HIV disease is a chronic, sometimes progressive immune disorder.

**NURSING CARE TIP**

More than any other chronic disease in recent history, AIDs challenges nurses to call into play all of their physical, emotional, social, and spiritual care skills. As you care for patients who are HIV-positive or who have AIDS, it is important for you to understand current information. Being informed helps you to provide caring, competent, nonjudgmental care without fear (Table 20.1). Knowledge about HIV/AIDS and its treatment continues to evolve with new discoveries.
The HIV epidemic was first reported by the CDC in June 1981. Cases of HIV infection and AIDS increased rapidly through the 1980s, followed by a decrease in the later 1990s. More than 1.1 million people are infected with HIV in the United States (Table 20.2) (www.cdc.gov/hiv/statistics/ataglance.html). In 2011, an estimated 49,273 people were newly infected in the United States, and the CDC estimated that one in six infected people were not aware of their status (www.cdc.gov/hiv/statistics/ataglance.html).

African Americans are estimated to have an incidence rate of new HIV infections that is eight times higher than that of Caucasians (www.cdc.gov/hiv/risk/racialEthnic/aa/facts/index.html). Women account for 25% of HIV infections (www.cdc.gov/hiv/risk/gender/women/facts/index.html).

Older adults are increasingly contracting HIV. Currently, 11% of new infections are in those aged 50 and older; patients in this age group must be educated about prevention (Brooks, 2012). Although HIV/AIDS can occur in a person of any age, this chapter focuses on adults with HIV/AIDS.

Infection with HIV causes destruction of immune cells. Without a normally functioning immune system, infections and cancers can take over. AIDS is the result of this immunodeficiency.

Two strains of HIV have been identified: HIV-1 and HIV-2. HIV-1 is found around the world, whereas HIV-2 is found mainly in a small area in West Africa. It is possible to
become infected with both strains of HIV. They are transmitted in the same way, have the same symptoms, are incurable, and can progress to AIDS. Tests that are sensitive to both strains identify the type of HIV. Because HIV-1 is most common, reference to HIV in this chapter is generally to HIV-1, unless noted.

HIV is a retrovirus (which only has ribonucleic acid [RNA] for genetic material). HIV is attracted to immune cells that have a surface-attaching site referred to as a CD4 receptor. Cells with CD4 receptors include lymphocytes (called CD4+ T lymphocytes, T4 lymphocytes, or helper T lymphocytes) and macrophages (in which HIV hides). HIV begins its infection by binding to the CD4 receptor of the host cell. The CD4+ T lymphocytes are the primary targets for HIV infection. Because CD4+ T lymphocytes orchestrate all immune functions, HIV’s attack on these cells results in progressive impairment of the body’s immune response. The CD4+ T lymphocytes do not function normally and are too busy replicating more HIV to perform their intended immune functions.

Understanding how HIV fuses with the cell has been the focus of treatments to block fusion of HIV with a host cell. After fusion occurs with a host cell, the HIV viral particle is taken into the cell and its covering is destroyed to expose its viral RNA. The retrovirus then uses an enzyme called reverse transcriptase to force the human cell to produce a new piece of deoxyribonucleic acid (DNA) from the viral RNA. The new DNA is then integrated into the person’s cellular DNA. As a result, the human cell creates more viral particles, which spread through the lymphoid system (Fig. 20.2). Inhibitors of reverse transcriptase were the first anti-HIV medications developed and are still an essential part of current treatment.

Once the genetic material of HIV has been changed to DNA, the enzyme integrase integrates it into the genetic material of the host cell. The cell is then translated into viral proteins. One of these proteins is HIV protease, which is required to process other HIV proteins into their functional forms. Protease inhibitors, potent types of anti viral medications, act by blocking this critical step. Following development of the cell surface, the virus then buds from the cell and is released to infect another cell. Thus the virus can spread throughout the body. HIV can persist in a latent (inactive) state for many years. There is no cure for HIV, but it can be controlled with lifelong anti viral treatment. The ultimate challenge is to use knowledge of the HIV life cycle to develop treatments that will eradicate HIV from those who are infected and to create a protective vaccine.

After a person has been infected with HIV, other immune system components form antibodies to fight HIV. These HIV antibodies typically become present within 3 to 6 months after infection. The time between infection and developing antibodies is called the window period. Testing for these antibodies can be done to diagnose HIV. Laboratory tests are available that detect the virus directly, but these are more costly for routine HIV testing.

After fusion occurs with a host cell, the HIV viral particle is taken into the cell and its covering is destroyed to expose its viral RNA. The retrovirus then uses an enzyme called reverse transcriptase to force the human cell to produce a new piece of deoxyribonucleic acid (DNA) from the viral RNA. The new DNA is then integrated into the person’s cellular DNA. As a result, the human cell creates more viral particles, which spread through the lymphoid system (Fig. 20.2). Inhibitors of reverse transcriptase were the first anti-HIV medications developed and are still an essential part of current treatment.

Once the genetic material of HIV has been changed to DNA, the enzyme integrase integrates it into the genetic material of the host cell. The cell is then translated into viral proteins. One of these proteins is HIV protease, which is required to process other HIV proteins into their functional forms. Protease inhibitors, potent types of anti viral medications, act by blocking this critical step. Following development of the cell surface, the virus then buds from the cell and is released to infect another cell. Thus the virus can spread throughout the body. HIV can persist in a latent (inactive) state for many years. There is no cure for HIV, but it can be controlled with lifelong anti viral treatment. The ultimate challenge is to use knowledge of the HIV life cycle to develop treatments that will eradicate HIV from those who are infected and to create a protective vaccine.

After a person has been infected with HIV, other immune system components form antibodies to fight HIV. These HIV antibodies typically become present within 3 to 6 months after infection. The time between infection and developing antibodies is called the window period. Testing for these antibodies can be done to diagnose HIV. Laboratory tests are available that detect the virus directly, but these are more costly for routine HIV testing.

**LEARNING TIP**

Being HIV-positive means that the person has been infected with the HIV virus. It does not mean that the person has AIDS.

**Progression of HIV Infection**

The initial infection is followed by a relatively symptom-free period called the clinical latency stage. The virus remains in the lymph nodes, liver, and spleen and reproduces. If the infection is untreated, CD4+ T lymphocytes gradually decrease. B lymphocytes also become dysfunctional and dysregulated by the events of HIV progression. B and T cells work together for a normal healthy immune system, so this can further impair the immune system. This period, from infection to the beginning of the symptomatic stage, varies for each person and averages 8 to 12 years. During
In this stage, the person is considered to be HIV infected. One in six persons (15.8%) do not know they are infected with the virus, causing increased rates of transmission related to uncontrolled viral loads from lack of HAART (www.cdc.gov/hiv/statistics/basics/ataglance.html). During the early symptomatic stage of HIV disease, symptoms of the weakening immune system are seen. When the immune system is severely weakened, opportunistic infections and cancers can occur (see Box 20-1).

**PREVENTION**

Education and prevention are the best ways to manage the HIV/AIDS epidemic (“Evidence-Based Practice”). Education regarding the disease and its transmission should begin with the older school-age child and include the general population, including older adults (www.cdc.gov) (see “Gerontological Issues”). Nurses can be advocates for this education.

**LEARNING TIP**

Opportunistic diseases are referred to as opportunistic (i.e., they take advantage of the opportunity to attack) because an uncompromised immune system would be able to fight off the infection. However, with HIV/AIDS, the immune system is weakened and unable to fight off the opportunistic infections.

**Gerontological Issues**

In 2013, the CDC reported 11% of new cases and 24% of all persons living with HIV/AIDS are over age 50. Numbers will continue to rise as the older population increases, yet little attention has been given to this age group. This can be due to an ageist view of the older adult and sexual activity. It is important to understand that HIV infection...
HIV is a fragile virus that is transmitted from person to person through infected blood, vaginal secretions, semen, breast milk, or body fluids containing blood. HIV is not spread casually and does not live long when outside the body. It needs a portal of entry into the body, such as a tear in a mucous membrane or nonintact skin, or access to the bloodstream or lymphatic tissue. Casual contact such as hugging, closed-mouth kissing, shaking hands, or sharing eating utensils, towels, or bathroom fixtures with an HIV-positive person does not transmit HIV. It is not transmitted in the air, water, food, or by insects. Since 1985, donated blood has been tested for HIV antibodies; donated organs are also tested, so infection is rare. Transmission within households from contact with infected blood or body secretions is also rare. Education for those living with someone infected with HIV is important (see www.cdc.gov/hiv).

Pre-exposure Prophylaxis (PrEP)

Pre-exposure prophylaxis (PrEP), with an ARV, is an effective way to prevent HIV transmission for those who are at high risk of contracting the virus. It is a daily pill and should be used along with appropriate other HIV transmission precautions.

EVIDENCE-BASED PRACTICE

Clinical Question
Does circumcision prevent HIV acquisition in heterosexual males, men who have sex with men (MSM), and females?

Evidence
Three large randomized controlled studies in Africa revealed strong evidence that male circumcision prevents men from acquiring HIV from heterosexual sex. However, in the MSM population, a randomized placebo controlled trial done in Peru and the United States reported that circumcision did not affect HIV transmission rates of 1,822 MSM over an 18-month study period. For women, there is some evidence of the benefit of male circumcision to prevent HIV transmission, but further research is needed (Padian et al, 2011; Sanchez et al, 2011; Siegfried et al, 2009).

Implications for Nursing Practice
Understanding current evidence-based HIV prevention measures is important in providing care and education to patients.

REFERENCES

LEARNING TIP
HIV can be transmitted to others within a few days of initial infection and throughout all phases of the HIV and AIDS infection.

Mode of Transmission
HIV is a fragile virus that is transmitted from person to person through infected blood, vaginal secretions, semen, breast milk, or body fluids containing blood. HIV is not spread casually and does not live long when outside the body. It needs a portal of entry into the body, such as a tear in a mucous membrane or nonintact skin, or access to the bloodstream or lymphatic tissue. Casual contact such as hugging, closed-mouth kissing, shaking hands, or sharing eating utensils, towels, or bathroom fixtures with an HIV-positive person does not transmit HIV. It is not transmitted in the air, water, food, or by insects. Since 1985, donated blood has been tested for HIV antibodies; donated organs are also tested, so infection is rare. Transmission within households from contact with infected blood or body secretions is also rare. Education for those living with someone infected with HIV is important (see www.cdc.gov/hiv).

Counseling
Early knowledge of HIV status helps reduce the spread of HIV infection. The CDC recommends routine testing for those aged 13 to 64 years old, pregnant females, or those who have been sexually assaulted. Testing is done either confidentially or anonymously. Permission is needed to release one’s test results. Posttest counseling is available to help the patient understand the test results, assist with informing sexual partners
and drug needle sharers, risk-factor reduction, and care options, if needed.

**Sexual Transmission**

HIV can be transmitted through sexual contact with infected body fluids and mucous membranes; some sexual contact carries a higher rate of transmission. Oral and anal sex have high rates of transmission for both males and females. Anal sex has the highest risk because it often results in tearing of the mucous membrane, allowing for exposure to infected semen. Females have a greater risk for becoming infected because the vagina has a greater area of mucous membranes than the penis, and there is a greater amount of HIV found in semen compared with vaginal secretions. The presence of a STI can increase the risk of transmission through an STI-related lesion.

Research has shown that starting early ARV therapy for HIV-infected individuals can reduce HIV transmission rates to uninfected sexual partners by 96% (Cohen et al., 2011). Visit [www.hptn.org/research_studies/hptn052.asp](http://www.hptn.org/research_studies/hptn052.asp) for more information. Studies are also looking at the benefits of PrEP with an ARV for non-HIV-infected people before sexual exposure to HIV. Results to date have shown effectiveness in preventing the sexual transmission of HIV (Grant et al., 2010). Visit [www.cdc.gov/hiv/prevention/research/prep/index.html](http://www.cdc.gov/hiv/prevention/research/prep/index.html) for more information.

**Safer Sex Practices**

Abstaining from sexual intercourse is the only sure way to prevent sexual exposure to HIV. A long-term, mutually monogamous sexual relationship is considered safest, when both partners have been tested and are HIV-negative. Using latex condoms correctly and regularly, limiting sexual partners, wearing latex gloves to protect hands during genital or anal contact, using condoms and dental dams (latex sheets) as a barrier for the mouth and genitals or anus and under-standing safer sex techniques reduce risk of HIV transmission (Box 20-2).

**Parenteral Transmission**

The best way to prevent parenteral transmission of HIV is to avoid or stop injecting drugs and enroll in a substance abuse treatment program. If a person who injects drugs is unable or unwilling to stop, it is recommended that a new sterile syringe and needle, obtained from pharmacies, is used each time injection equipment, and alcohol swabs to clean the injection site. Afterward, the syringe should be safely disposed of. Drug injection equipment should never be shared or reused. Syringe exchange program availability varies by location, although these programs have been shown to decrease the risk of transmission of HIV and other bloodborne pathogens. If injection equipment is reused, it should be boiled or cleansed with bleach. Additionally, sexual activity should be discouraged when judgment is impaired from drug use because protective measures, which should be taught, may not be used. Research showed that PrEP with an ARV for non-HIV-infected people who inject drugs was effective in reducing HIV exposure by 49% (Choopanya et al., 2013). This is another option for reducing HIV transmission risk.

Autologous (one’s own) blood transfusion, when possible, is the safest type of blood transfusion to prevent HIV infection. There is a reported 1 in 1.8 million units chance of HIV transmission from donated blood that is infected but has not yet had time to develop antibodies.

**Perinatal Transmission**

Guidelines for HIV screening of pregnant women recommend that HIV counseling and testing be offered during routine prenatal care for all pregnant women and again in the third trimester for women at high risk (Branson et al., 2006). All pregnant women who are HIV-positive can reduce the risk of perinatal HIV transmission to less than 1% by taking ARV therapy (including zidovudine [AZT]) during pregnancy, labor, and delivery. At the time of labor, pregnant women who have not been tested for HIV should be offered rapid HIV tests, and therapy should be started if HIV is confirmed. After delivery, the infant of a mother with HIV is given AZT for 6 weeks.

**Health Care Providers and HIV Prevention**

Occupational HIV transmission is rare. Using standard precautions (see Chapter 8), performing hand hygiene after contact with body fluids, and using safety devices to prevent needlesticks (needles systems, protective covers, and not recapping used needles) or other injuries reduce the risk of HIV exposure. It is essential to understand and use these practices with all patients to protect yourself from exposure and transmission of HIV. If you are unsure of the appropriate personal protective equipment or isolation precautions to
use, ask your instructor or the patient’s nurse before providing care to the patient.

Know the occupational exposure protocol for the agency or hospital in which you are employed. If an exposure occurs, wash the exposure site with soap and water immediately. For mucous membrane exposure, flush with water and then report to the closest emergency room immediately for further assessment and possible treatment. The U.S. Public Health Service guidelines for occupational exposures can be viewed at www.jstor.org/stable/10.1086/672271.

**HIV SIGNS AND SYMPTOMS**

Each patient’s HIV response is different. Initially after HIV infection, the patient can have no symptoms or can develop acute retroviral syndrome with symptoms of extreme fatigue, headache, fever, lymphadenopathy (enlarged lymph nodes in two sites other than inguinal nodes), diarrhea, or a sore throat (Fig. 20.3 and Table 20.3). Symptoms typically develop 6 to 12 weeks after HIV transmission and can last a few days to weeks. These symptoms are usually mild and not attributed to the HIV infection.

After an extended asymptomatic phase, untreated HIV infection usually progresses to a symptomatic stage when the virus has greatly impaired the immune system. The patient can have shortness of breath, fever, weight loss, fatigue, night sweats, persistent diarrhea, oral or vaginal candidiasis ulcers, dry skin, skin lesions, peripheral neuropathy, shingles (varicella zoster virus reactivation), seizures, or dementia. In the final stage of HIV infection, AIDS is diagnosed when the CD4+ T-lymphocyte count is below 200 or opportunistic infections and diseases, with their specific signs and symptoms, occur (see Box 20-1).

**COMPLICATIONS**

Complications from HIV/AIDS vary from patient to patient. With HAART, fewer complications are seen than in the past. Some, such as Kaposi’s sarcoma (a connective tissue tumor), are rarely seen anymore. A few complications are discussed next.

**AIDS Wasting Syndrome**

AIDS wasting syndrome is defined by involuntary loss of more than 10% of baseline body weight plus chronic weakness or fever or chronic diarrhea for more than 30 days. Several factors contribute to this syndrome: decreased appetite, oral lesions, altered metabolism, malabsorption, gastrointestinal (GI) infections, diarrhea, medication side effects, and cognitive impairment. The progressive weight loss impairs the function of all body systems from malnourishment. Careful planning, intervention, and education of the patient when HIV is first diagnosed can help maintain body weight.

**HIV-Associated Neurocognitive Disorder**

HIV infection in the brain or other parts of the central nervous system (CNS) results in CNS conditions with varying degrees of severity. Examples include asymptomatic neurocognitive impairment, minor neurocognitive disorder, and HIV-associated dementia [HIV encephalopathy or AIDS dementia complex]. Symptoms range from mild to severe and can include memory impairment, personality changes, hallucinations, leg weakness, loss of balance, and slower responses. In advanced AIDS, with HAART, AIDS dementia complex is less common than before and minor cognitive motor disorder has become more common. When CNS changes occur, safety is an important consideration for the patient and caregiver.
Cancer and Opportunistic Infections

Why would a person with HIV/AIDS have increased risk for cancer and opportunistic infections? With an impaired immune system, the incidence of certain kinds of cancer rises because the immune system is not able to destroy the abnormal cells. Opportunistic infections, which a healthy immune system could fight, are also a complication of HIV/AIDS. Infections that develop even with a healthy immune system, such as tuberculosis, can also occur. Opportunistic infections can be viral, bacterial, mycobacterial, fungal, protozoal, or parasitic. They can affect many areas of the body. Some opportunistic infections can now be prevented with prophylactic treatments. Some infections are discussed here.

Candida Albicans

*Candida albicans* is a fungus normally found in the GI tract that does not infect a person with a healthy immune system. In AIDS, overgrowth of this fungus occurs. Candidiasis of the mouth or esophagus is common in AIDS. Signs and symptoms of candidiasis include oral or esophageal pain, dysphagia, and yellow-white plaques that look like cottage cheese in the mouth and throat. Nutrition can be affected by oral or esophageal candidiasis. Recurrent vaginal candidiasis, with severe itching and a white discharge, is common in women with AIDS.

Cytomegalovirus

*Cytomegalovirus* (CMV) infection can be serious for those with HIV/AIDS, especially when CD4+ T-lymphocyte counts fall below 100/mm³. It can cause retinitis, which can result in blindness. Other symptoms can include fever, fatigue, diarrhea, GI upset, and hepatitis.

Mycobacterium Avium Complex

*Mycobacterium avium complex* (MAC), a serious bacterial infection, can occur in those with AIDS when CD4+ T-lymphocyte counts drop below 50. MAC is found in water, food, and soil, so a voidance is difficult. Prophylactic drugs when CD4 counts fall below 50 include azithromycin, clarithromycin, or rifabutin. With infection, symptoms can include fever, night sweats, weight loss, abdominal pain, tiredness, and diarrhea. Treatment includes a combination of clarithromycin and ethambutol, and possibly rifabutin.

Pneumocystis Pneumonia

*Pneumocystis jiroveci* in immunocompromised persons. PCP develops slowly and produces shortness of breath, fever, and dry cough. When CD4+ T-lymphocyte counts fall below 350/mm³, prophylactic oral trimethoprim-sulfamethoxazole (TMP-SMX [Bactrim, Septra, Cotrim]) is recommended. PCP is less likely to occur than in the past with TMP-SMX but remains a concern for those with HIV/AIDS. PCP can be treated with oxygen, TMP-SMX, or pentamidine isethionate. Steroids can help reduce lung inflammation.
• An enzyme-linked immunosorbent assay (ELISA) test is done to detect antibodies to HIV antigen in the patient’s blood using test plates.
• If positive, the ELISA test is repeated because false positives can occur (0.1%).
• If the ELISA test is again positive, the Western blot test is done to detect the presence of antibodies to four major HIV antigens. The test is positive if two antibodies are present.
• If all test results are positive, the patient is HIV-antibody positive.

Nursing Care Tips

When assessing the results of a TST, only the induration (palpable, raised, hardened area or swelling) is measured across the forearm and recorded in millimeters. If there is no induration, it is recorded as 0 mm.

Tuberculosis

Tuberculosis is a bacterial infection caused by the mycobacterium tuberculosis. Symptoms include dyspnea, cough, chest pain, fever, night sweats, and weight loss. A Mantoux tuberculin skin test (TST) with tuberculin purified protein derivative should be performed at least yearly in patients with HIV infection. Induration of 5 mm or more is defined as a positive result in patients with HIV infection and so defines the development of AIDS (see Chapter 31).

DIAGNOSIS

HIV screening is recommended for people from 15 to 65 years of age at least once (Moyer, 2013). Those with increased risk outside of this age range should also be screened. For those at high risk, screening should occur more frequently.

Fingerstick blood, oral fluid (OraQuick Rapid HIV test—swab of complete upper and lower outer gums), and serum specimens can be used for HIV testing. Urine can also be tested but is slightly less accurate. Results can be available in less than 20 minutes with the Multispot HIV-1/HIV-2 Rapid Test or in 1 hour for immunoassay (IA) testing. Consumer-controlled test kits (home sample collection devices) can be purchased at drug stores; the blood sample is sent in for HIV testing, with the individual anonymously calling for results, purchased at drug stores; the blood sample is sent in for HIV testing, with the individual anonymously calling for results, counseling, and referral if needed.

After HIV infection, antibodies cannot be formed for 3 weeks to 3 months or longer in some cases. Early-detection HIV tests are available for detection as soon as 1 week after potential exposure.

HIV Antibody Tests

The traditional HIV-1 antibody testing pattern:

• If the test is negative, the patient is said to be in the window period or HIV negative.
• Other tests can be used, especially if initial test results are not conclusive. Testing directly for the virus is available but more costly.

New testing guidelines were evaluated in 2011–2013 by the CDC to reduce missed HIV diagnoses. Third- and fourth-generation immunoassays are very sensitive and can be positive when the confirming tests are falsely negative. This false result can lead to delayed treatment and continued transmission of HIV. For a positive HIV immunoassay result and a negative antibody test result, additional testing to detect the virus directly is needed to confirm an acute HIV infection. (Visit www.cdc.gov for testing guidelines).

Complete Blood Cell Count/Lymphocyte Count

Because patients with HIV are susceptible to leukopenia, lymphopenia, anemia, and thrombocytopenia related to HIV infection and as a complication of antiretroviral therapy, a complete blood cell count (CBC) including a lymphocyte count should be obtained. The CBC should be repeated at 3- to 4-month intervals or more often if there is a change in therapy or the patient’s clinical course is unstable.

CD4+/CD8+ T-Lymphocyte Count

The count of CD4+ and CD8+ (cytotoxic cells) T lymphocytes is essential for evaluating the status of the immune system. In healthy adults, CD4+ levels average 500 to 1600 cells per mm3. In HIV/AIDS, CD4+ cell levels drop but CD8+ cell levels do not. A low ratio of CD4+ cells to CD8+ cells is seen as HIV/AIDS progresses. It is recommended that CD4+/CD8+ T-lymphocyte counts be performed at 3-month intervals for most patients, especially those on ARV therapy.

Viral Load Testing

Viral load testing measures the amount of HIV RNA in plasma and is extremely important for determining the risk of disease progression if left untreated, the risk of opportunistic infections, and the response to ARV therapy. Combination ARV regimens usually produce a 50% decrease in total-body HIV levels within just a few days. Viral loads should be performed 1 month after starting new treatments and at 3-month intervals thereafter. The goal on ARV therapy is to obtain and maintain an ultrasensitive undetectable viral load.

Genotyping

Genotyping measures resistance to currently available ARV treatments. This information guides HCPs in choosing treatment regimens that will most likely be effective against that person’s virus.

General Tests

Standard serological testing for syphilis is recommended annually in patients who are sexually active. Hepatitis A, B, and C serologies and liver chemistry panels are indicated in the early evaluation because of the high incidence of concurrent hepatitis coinfection for HIV-positive patients. Coinfections...
can influence the course of either the patient’s HIV or the coinfection. It can also affect the HIV treatment options.

**THERAPEUTIC MEASURES**

The goal of therapy is to prevent or delay development of opportunistic diseases. In 2013, the federal *Guidelines for the Use of Antiretroviral Agents in HIV-1 Infected Adults and Adolescents* was updated (Panel on Antiretroviral Guidelines for Adults and Adolescents, 2013). They recommend that all patients with HIV be started on HAART, independent of CD4 count. In addition, to increase life expectancy and treatment cost-effectiveness, it is recommended for patients to be prophylactically treated for opportunistic infections, especially hepatitis A and hepatitis B viruses, herpes simplex virus, *Mycobacterium avium* complex, and *Pneumocystis jiroveci* pneumonia (Table 20.4). Other opportunistic infections are treated with appropriate medications if they occur.

ARV drugs that inhibit reproduction of the virus (but do not kill it) are used to treat HIV infection. These ARV agents have been developed to act predominantly on processes specific to the viral particle to protect the integrity of the host cell. Strategies specifically aimed at interrupting the viral life cycle include the following:

- Preventing the virus from attaching to the CD4+ receptor of the T4 lymphocyte
- Interfering with “uncoating” of the virus within the cell, the first essential step in allowing the virus to integrate into the cell’s DNA
- Inhibiting reverse transcriptase, a viral enzyme specific to retroviruses, which enables the virus to make a DNA copy

---

**HIV wasting**

*Patient education:*
- Eat frequent small high-calorie and high-protein meals with snacks daily.
- Eat low-residue diet for diarrhea control.
- Control odors if they cause nausea.
- Develop easy meal plan: favorite foods, meal programs, frozen dinners, cold food to control nausea.
- Use antiemetics, appetite stimulants, and/or testosterone.
- Rest, listen to music.
- Numb painful oral sores with ice, popsicles, or topical analgesic; avoid spicy foods.
- Use artificial saliva for dry mouth.
- Use nutritional supplements.
- Use food stamps, community food pantries, or free meal programs as needed.
- Exercise to increase muscle mass.
- Take medications prescribed to treat HIV wasting.
from single-stranded viral RNA before integration into cellular DNA

- Blocking viral regulatory and transactivating proteins, which are involved in the transcription and translation of viral RNA proteins from proviral DNA as the virus goes from the quiet, integrated state to active replication
- Inhibiting protease, a viral enzyme responsible for the adherence of viral proteins both before proviral integration and as the viral particles recombine into functional proteins needed for viral maturation
- Preventing viral assembly and budding out of the cell.

For more information, visit the AIDS Info quick reference guide to ARVs at [http://aidsinfo.nih.gov/drugs](http://aidsinfo.nih.gov/drugs).

**ARV Therapy**

Aggressive treatment with cocktails of multiple ARV drugs aim to reduce viral loads to undetectable levels in the bloodstream which increases CD4+ T lymphocyte counts, resulting in prolonged survival and quality of life. There are six drug classes of HIV treatment available. Each class affects the virus in a different stage of its life cycle. Use of these drugs in combination is referred to as antiretroviral therapy (ART). Usually at least three medications in at least two classes of treatment categories are used (Table 20.5).

The major cause of drug resistance occurs when medications are not taken as directed so teaching is important. **Adherence** is the word used to describe taking medications properly as prescribed.

</tbody>
</table>
exactly as directed. Another increasing potential cause of drug resistance is when an infected person with resistant virus exposes another infected person to the resistant virus through unprotected sexual exposure or injected drug use.

Many anti-HIV drugs have side effects. If they occur, the drug regimen can be changed or interventions can be used to help control the side effects. The patient should be taught about side effects and instructed always to report them immediately, especially rashes (such as with trimethoprim-sulfamethoxazole) and abdominal pain (such as with AZT [Retrovir]); they could be serious or even life threatening.

When someone with a suppressed immune system (very low CD4/T-cell count) is started on ART, the person can experience immune reconstitution syndrome. The patient’s immune system is greatly improved and the immune system begins to fight off infections that were already present in the body such as Pneumocystis jiroveci pneumonia, symptoms can arise.

NURSING CARE TIP

Medication Adherence Teaching
Teach patients that it is essential to take all medications as ordered. Missing just 10% of medication doses (1 of 10) decreases effectiveness to about 80%, depending on the drug. This means that if a patient is taking three to seven pills each day, missing one to two pills a week will decrease the medications’ effectiveness by 20%.
This can be a serious, sometimes fatal condition that can occur a few weeks after antiretroviral therapy starts. Educating the patient to report immediately any symptoms of opportunistic infections after starting therapy can allow for prompt diagnosis and treatment of the infection—and can save the person’s life.

**NURSING PROCESS FOR THE ADULT PATIENT WITH HIV/AIDS**

**Data Collection**

Ongoing monitoring is important for the patient with HIV/AIDS to detect problems early. Health history information is obtained (Box 20-3). Determining the patient’s understanding of HIV/AIDS information is necessary for planning and teaching. A physical examination provides data on the effects of HIV/AIDS and ARTs. Monitoring the patient’s level of pain is ongoing; however, many patients with HIV do not have pain related to their HIV. You should also check for signs and symptoms of opportunistic infections.

**LEARNING TIP**

Key points to remember:
- HIV and AIDS are disease labels, not people labels.
- Each person reacts to an HIV or AIDS diagnosis differently.
- It is not the HIV that ultimately causes death; it is compromised immunity and the invasion of an opportunistic infection or disease that the patient’s body is unable to successfully fight off, even with medical intervention.
- With today’s successful ARTs, HIV has changed from being a life-ending infection to a chronic disease requiring constant management.

**Box 20-3 Data Collection: Health History Information for HIV/AIDS**

- Demographic data: gender, age, marital status, occupation, residence
- Date of diagnosis of HIV/AIDS
- Past medical history and surgeries
- Current health status and concerns
- Allergies
- Medication history of antivirals used with reason for discontinuing
- Current medications, dose, and frequency (including over-the-counter medications and supplements)
- Immunizations
- Family history
- Height/weight: weight loss
- Infections/cancers (see Box 20-1, “CDC Conditions in the AIDS Surveillance Case Definition”)
- Sexually transmitted infections and treatments
- Social history, sexual practices, risk behaviors, safe sex practices
- Needle and blood exposure, injection drug use, blood transfusions/treatment for hemophilia
- Tobacco use
- Drug and alcohol use
- Exercise and sleep
- Pets
- Occupational history
- Nutrition history
- Female: gynecological history, last Pap test

**Nursing Diagnoses**

Nursing care is individualized to the patient’s presenting symptoms. Nursing diagnoses for HIV/AIDS can include the following:
- **Ineffective Protection** related to decreased immune function
- **Impaired Gas Exchange** related to respiratory infection
- **Acute or Chronic Pain** related to neuropathy, cancer, infection, or dyspnea
- **Fatigue** related to HIV infection and/or side effects of treatments
- **Risk for Injury** related to weakness, fatigue, sedation, neurologic impairment
- **Imbalanced Nutrition: Less Than Body Requirements** related to anorexia, nausea and vomiting, increased caloric need, diarrhea, dysphagia, oral lesions
- **Impaired Oral Mucous Membrane** related to decreased immune function
- **Diarrhea** related to infection, medications
- **Impaired Skin Integrity** related to infection, cancer, immobility, incontinence
- **Social Isolation** related to fear of disclosure of status, infection control, transmission of virus
- **Risk for Situational Low Self-Esteem** related to body image changes
- **Deficient Knowledge** related to lack of previous experience with HIV/AIDS and treatment
- **Grieving** related to loss of function or death
- **Disabled Family Coping** related to chronic, potentially progressive disease
- **Ineffective Coping** related to chronic progressive disease
- **Ineffective Sexuality Pattern** related to fear of disease transmission.

See the Nursing Care Plan for the Patient With AIDS.
Planning and Implementation

HIV/AIDS can affect every system of the body and every aspect of a person’s life. Nurses have the opportunity to positively influence the patient’s experience with HIV/AIDS by providing a nonjudgmental approach, empathy, and psychological support.

INEFFECTIVE PROTECTION. To reduce infection risk, the patient should be taught to wash hands frequently, especially before eating and after toileting; bathe regularly; avoid sharing personal grooming items (e.g., toothbrush, toothpaste, razor); wash toothbrush; and wash all dishes between uses (Table 20.6). In addition, the patient is taught signs of infection to report to the health care provider immediately (Box 20-4, “Patient Education”). Treatment of opportunistic infections is most effective when begun early.

IMPAIRED GAS EXCHANGE. If a patient develops a condition that interferes with respiration, the goal is to maintain oxygenation within normal limits and reduce dyspnea. PCP is a potential respiratory infection with AIDS (see Table 20.4). Monitoring the patient’s vital signs, including respiratory rate, depth, rhythm, and oxygen saturation, is important. Medications and oxygen therapy are given as ordered. Positioning the patient for comfort is often done by raising the head of the bed. Assisting with activities helps reduce fatigue.

</tbody>
</table>

Water safety:  
Avoid public drinking fountains.  
Avoid drinking or swallowing water directly from lakes or rivers.  
Use safe water supply or boil water for 1 minute when unsure.  
Avoid beverages made from tap water in public places in areas where water sources are known not to be safe.  
Drink bottled water purified from reverse osmosis, filtration through absolute 1-micrometer filter, or distillation (only safe methods) in areas where water sources are known not to be safe. For information, contact [www.bottledwater.org](http://www.bottledwater.org).  
Bottled or canned carbonated soft drinks, commercially packaged unrefrigerated beverages, pasteurized beverages, and beers are safe.

Cook meat until internal temperature is 180°F (82.2°C) for poultry, 165°F (73.8°C) for red meats, with no trace of pink.

Foods to avoid or cook until steaming hot: leftovers, ready-to-eat, delicatessen foods, refrigerated pâtés, and meat spreads.

Box 20-4 Patient Education

**Signs and Symptoms of Opportunistic Infections to Report**

Teach patient to monitor temperature and to report the following symptoms to a health care provider immediately:

- New fever higher than 100°F (38.5°C) or a change in fever pattern if low-grade fevers are common
- Cough, shortness of breath, fever, or chest tightness, which can be signs of early pneumonia
- Signs of central nervous system infection, such as severe headache; stiff neck; visual changes; problems with balance, walking, or speech; weakness of an arm or leg; or changes in moods or memory
- Foul-smelling drainage or pus
- Cloudy or foul-smelling urine
- Signs of dehydration, such as a dry mouth, dark concentrated urine, or dizziness when standing
- Diarrhea lasting longer than 48 hours; more than six stools a day; watery, mucousy, or bloody stools
- Rashes (possible side effect of medication)
- Sore mouth or tongue, difficulty swallowing, white patches on tongue or back of mouth
- Worsening fatigue
- Change in vision and if floaters develop
- Unintended weight loss
Chapter 20  Nursing Care of Patients With HIV Disease and AIDS  379

PAIN. Pain can occur from a variety of causes. Treatment is focused on the cause to achieve pain control and relief. Medications can be given as ordered. Timing medication administration before planned activities is helpful in increasing ability to function. Complementary therapy can be used by patients (see Chapter 5). Measures such as heat or cold, massage, and frequent position changes can be helpful.

FATIGUE. Some patients with HIV experience fatigue. Other causes of fatigue include infections, medications, anemia, dehydration, depression, and poor nutrition. The patient can help manage fatigue by alternating periods of activity and rest. Tasks that use more energy should be planned at times when the patient is most energetic. Helping a patient prioritize activities is important in planning the best use of the energy available.

IMBALANCED NUTRITION: LESS THAN BODY REQUIREMENTS. Maintaining general health and nutrition is important for a healthy immune system. For patients with HIV, maintaining nutrition is vital (see “Nutrition Notes”). Patients with AIDS can have difficulty maintaining adequate nutrition and preventing weight loss. Many factors interfere with nutrition in HIV/AIDS (e.g., anorexia, oral lesions, nausea and vomiting, diarrhea, or wasting syndrome). The cause needs to be identified for appropriate intervention planning.

Nutrition Notes

Nourishing the Patient With HIV or AIDS

Nutrition has preventive and therapeutic functions for patients with HIV infections. Well-nourished people infected with the HIV virus are better able to resist opportunistic infections and tolerate the side effects of treatment. Multiple studies have found that the use of a nutritional supplement delayed the onset of advanced disease in HIV-positive people (Botros, Somarriba, Neri, & Miller, 2012). The person infected with HIV displays reduced appetite possibly due to oral infections and diarrhea from damage to intestinal cells that interferes with absorption of nutrients. Coupled with nausea and vomiting related to medications, the clinical picture often leads to loss of weight and lean body mass. Malnutrition adds fuel to the fire by accelerating the progress of HIV infection to AIDS. An HIV-infected adult requires 10% to 15% more energy per day and approximately 50% to 100% more protein than someone not infected (Duggal, Chung & Duggal, 2012). The current World Health Organization recommendation for an intake of micronutrients at Recommended Dietary Allowance levels is a reasonable target for persons with clinically stable HIV infection (Forrester & Sztam, 2011).

Diet should be integral to the treatment plan. Effort should be made to feed the patient orally. Strategies that can be helpful are as follows:

• Offer small, frequent feedings.
• Serve food cold or at room temperature.
• Alter seasonings.
• Add powdered milk to mashed potatoes or puddings to increase calories and protein.
• Modify texture to accommodate chewing difficulty or oral lesions.
• Provide nutritional supplements (e.g., Boost or Ensure)

The patient’s baseline weight is obtained. Then ongoing monitoring of the patient’s weight, calorie intake, and intake and output is done. A dietitian is consulted to help plan nutritious and affordable meals. The patient should be on a high-calorie, high-protein diet. Small, frequent meals can be helpful. Vitamins and/or nutritional supplements can be needed to maintain adequate nutrition. Antiemetics are used to control nausea and vomiting, if present. Medications that help stimulate appetite can be helpful. Easy-to-prepare meals are helpful when energy is limited. Creative interventions and resources can be needed to ensure the patient receives adequate nutrition (see “Nutrition Notes”). Along with adequate nutrition, exercise helps maintain muscle mass, promotes relaxation, aids sleep, and gives the person a sense of control and well-being. An effective exercise program includes exercises that increase strength, flexibility, and endurance. For many, becoming physically fit is a lifestyle change that requires dedication.

IMPAIRED ORAL MUCOUS MEMBRANE. Oral or esophageal candidiasis is more common in the late stage of AIDS. The painful lesions interfere with swallowing and nutrition. In patients with AIDS who smoke, there is an increased incidence of oral thrush (candidiasis). Therefore, patients should be encouraged to quit smoking. Antifungal medication is given. Mouth care is important. A soft toothbrush promotes comfort. Xylocaine viscous (Lidocaine viscous) can be given to decrease pain during eating.

DIARRHEA. Diarrhea can occur in patients with HIV. Diarrhea can be caused by HIV infection, opportunistic infections, or ARTs. An antimotility agent can be prescribed. Consulting the dietitian can be helpful in making dietary changes that reduce diarrhea (e.g., low-residue diet, no dairy products, no spicy foods, no caffeine or alcohol). Sitz baths can be soothing. Thorough cleansing of the anal area after each stool is a must. Ointments can be applied to protect and soothe the anal area from excoriation.

IMPAIRED SKIN INTEGRITY. Many skin conditions can occur with HIV infection. Medications can cause skin infections that can be life threatening and must be reported immediately. A dermatologist can need to be consulted to help diagnose and treat skin infections.

SOCIAL ISOLATION. Unfortunately, many patients with HIV/AIDS continue to face discrimination, rejection, and isolation. The Americans With Disabilities Act (ADA) makes discrimination toward patients with HIV illegal. Even relatives, friends, and others sometimes a void or refuse to have anything to do with the person with HIV.
NURSING CARE PLAN for the Patient With AIDS

**Nursing Diagnosis:** Ineffective Protection related to immune disorder, inadequate nutrition, intravenous (IV) therapy, and possible invasive procedures

**Expected Outcomes:** The patient will remain free of hospital-acquired infections. Patient will describe measures to maintain skin integrity and avoid infections.

**Evaluation of Outcomes:** Is patient free of hospital-acquired infections? Can patient explain and demonstrate skin maintenance techniques?

**Intervention** Identify patient’s risk factors, such as skin condition, laboratory results, portals of entry for infections, and presence of any infections. **Rationale** Status of these assessment factors determines plan for care.

**Intervention** Caregivers should use standard precautions and strict aseptic technique for all patients and procedures. **Rationale** Transmission of microorganisms can occur in both directions. Many patients with HIV are not aware of their HIV status. **Evaluation** Do all caregivers use standard precautions?

**Intervention** Instruct visitors about techniques to avoid transmission of infection, such as hand hygiene and not visiting when they have an infection. (Use extreme caution not to divulge the patient’s HIV/AIDS status to visitors/family.) The nurse with an infection, especially respiratory infection, should not care for the patient with AIDS. (If you must care for the patient, wear a mask and explain why you are wearing it.) **Rationale** The immune system is damaged by HIV. Ability to combat infections can be severely compromised. A minor infection for most people can kill a person who has AIDS. **Evaluation** Do those with infections avoid contact with patient until their infection is resolved? Do laboratory tests indicate that patient is so immunocompromised that reverse isolation can be necessary?

**Intervention** Promote skin integrity by frequent turning, optimum mobilization, use of protective mattress and chair pads, application of emollient to dry areas, and prompt treatment of any injuries. **Rationale** Skin is the body’s first line of defense. **Evaluation** Does patient’s skin remain intact and infection free?

**Intervention** Teach strategies for skin care and avoidance of infection to patient. **Rationale** Self-care offers a measure of control in a frequently uncontrollable situation. **Evaluation** Does patient satisfactorily explain or demonstrate good skin care and knowledge of how to avoid infection?

**Nursing Diagnosis:** Risk for Injury related to impaired mobility, weakness, fatigue, possible electrolyte imbalances, neurologic impairment, and sedative effects of pain medications

**Expected Outcome:** The patient’s care and mobility needs will be met without injury.

**Evaluation of Outcome:** Does patient remain free from injury?

**Intervention** Identify patient’s abilities and disabilities. **Rationale** Particular disabilities can increase danger to patient. **Evaluation** Does patient have deficits?

**Intervention** Look for potential hazards in environment (hospital or home) and eliminate as many hazards as possible. **Rationale** Awareness of hazards is necessary to decrease occurrence of accidents and injuries. **Evaluation** Are there currently any hazards in the environment?

**Intervention** Instruct patient about how to avoid hazards (if cognitively and physically able to comply). **Rationale** Patients can help avoid injury if they understand hazards. **Evaluation** Is patient effectively avoiding hazards, or is patient a danger to self?
NURSING CARE PLAN for the Patient With AIDS—cont’d

**Intervention** Encourage self-care as much as is feasible without tiring patient. **Rationale** Self-care promotes feelings of self-efficacy and can combat depression. **Evaluation** Does patient evidence satisfaction with self-care efforts?

**Intervention** Assist with care activities as needed. **Rationale** Varying levels of assistance with care are necessary due to the potentially debilitating nature of disease. **Evaluation** Are patient’s care and mobility needs being met satisfactorily without injury?

**Intervention** Institute safety measures as required, such as close observation, frequent reorientation, two staff members for ambulation, use of side rails, bed motion alarm, or room near nurse’s station. **Rationale** Protection of patient against inadvertent removal of tubes or equipment, falls, and other injuries can require extraordinary measures due to neurologic damage. **Evaluation** Are safety measures effective for patient? Does patient respond negatively to the protective measures? Can these be modified to be less offensive?

**Nursing Diagnosis:** Ineffective Coping related to potentially terminal disease and progressive debility

**Expected Outcome:** The patient will show use of effective coping skills.

**Evaluation of Outcome:** Does patient show use of effective coping skills?

**Intervention** Establish and maintain open and trusting therapeutic relationship. **Rationale** Effective communication is based on trust—assurance of confidentiality is essential. **Evaluation** Does patient talk about concerns with nurse?

**Intervention** Allow grieving to take place (keeping a journal has been effective for some patients who have AIDS). **Rationale** AIDS brings about losses of health, strength, employment, and, in many cases, friends; it threatens one’s sense of security and life. Healthy grieving is a natural coping response. **Evaluation** Is grief being expressed? Is patient finishing things that matter to him or her?

**Intervention** Encourage patient to express feelings and concerns. Contact counselor, chaplain, or AIDS support worker if patient so desires. **Rationale** Talking about feelings and concerns helps defuse anger, clarify needs, and relieve tension. **Evaluation** How are family members, friends, and support persons interacting with patient? How is patient responding to family members, friends, and support persons?

**Intervention** Provide patient with desired information or refer to others who can supply information. **Rationale** Knowledge dispels unreasonable fears and helps patient prepare adequately to cope with stressors. **Evaluation** Does patient evidence enough understanding of disease to be able to cope effectively?

**Intervention** Ask if patient would like information about support group and arrange such. **Rationale** Social support can help patient cope. **Evaluation** Does patient show satisfaction with coping resources?

Source: Linda Hopper Cook.

Misunderstanding and fear lead to misuse of infection control procedures and increase a patient’s isolation. Being knowledgeable about the transmission of HIV allows interaction with the patient to reduce feelings of isolation. Providing patient education to reduce fear of HIV transmission also decreases isolation. Taking care to maintain confidentiality is essential. It is important to be a ware that many patients with HIV do not share their diagnosis with family or friends who visit when they are hospitalized.

**RISK FOR SITUATIONAL LOW SELF-ESTEEM.** Changes in self-esteem and self-concept occur from several of the effects of HIV infection. Patients often experience changes in their relationships with others and in day-to-day activities such as work. Major weight loss and changes in fat distribution from
ARV agents, a condition called lipodystrophy, can cause dramatic changes in appearance that alter body image and reduce self-esteem. Tesamorelin (Egrifta) is used to treat lipodystrophy. Nurses can assist patients in maintaining self-esteem and self-concept by ensuring a climate of acceptance and promoting a trusting relationship. Patients should be encouraged to express feelings, if ready, and to identify positive aspects of self. Receiving emotional and spiritual support can help improve the patient’s self-esteem.

Stress has an impact on health. Having others to talk with and provide support is essential to stress management. Identifying and maintaining social networks is important. Patients should be taught a variety of relaxation strategies and techniques to reduce stress. Relaxation strategies can range from working on a favorite hobby to talking with friends. Relaxation techniques include progressive muscle relaxation and imagery to aid in relaxation. Stress management techniques are most effective when used every day, not just during times of stress.

**DEFICIENT KNOWLEDGE.** Extensive teaching is needed for patients to understand this chronic, potentially life-threatening disease that alters everything in their lives. (See also “Prevention” earlier in the chapter.) Teaching is evaluated for understanding and provided as the patient is ready. Understanding of adherence to treatment and medication regimens is essential to prevent resistance to treatment and reduce the risk of disease progression.

**CRITICAL THINKING**

**Zoe Sampson**

- Zoe, 22, is diagnosed as HIV-positive. She is tearful and asks many questions.
  1. How would you answer her questions?
     a. “Am I going to die?”
     b. “How is AIDS diagnosed?”
     c. “Can my boyfriend get it?”
  2. What food and water safety methods would you teach her?
  3. Years later, Zoe loses weight and becomes malnourished. What interventions can you use to promote adequate nutrition?

*Suggested answers are at the end of the chapter.*

**MEDICATIONS.** Nurses must stress during patient teaching that medication doses must not be missed. Using teaching aids to assist patients in remembering to take their medications is important. Encourage the patient to take medications exactly as instructed. If a dose is missed, it should be taken as soon as possible unless it is very close to the time of the next dose. Doses should not be doubled. Missing doses of medication could cause therapy failure because viral loads can increase and resistance to current treatments can develop. Strongly encourage the patient to consult promptly with the primary care provider with any questions or side effects. Many of these medications can cause severe reactions.

**FOOD AND WATER SAFETY.** Food and water safety are vital to an immunocompromised patient. Bacterial, viral, protozoal, or parasitic pathogens can cause foodborne and waterborne infections. The patient must be taught methods to prevent foodborne and waterborne infections for all phases of handling (see Table 20.6). Kitchen counters and food preparation appliances (e.g., cutting boards, can openers) should be disinfected. Freezing does not kill bacteria in foods. Foods should not be thawed at room temperature. Dating and using the oldest foods first is helpful. If symptoms of foodborne or waterborne infection develop (e.g., diarrhea, nausea, vomiting, abdominal cramps, headache, fever), teach patient to report them immediately. In certain areas of the country, tap water is not safe to drink. Patients need to be taught to boil water for drinking and making ice cubes or to drink bottled water.

**RESOURCES.** Financial resources can need to be addressed so that food and medications can be obtained. Treatment can be expensive, and the patient may be unable to work. However, with the new combination ARTs, many people are now able to continue working longer. The Ryan White Comprehensive AIDS Resources Emergency (CARE) Act provides funding for some services and treatment-related needs. Knowledge of local resources and referrals to financial resources and support groups are very important.

**COMMUNITY AND HOME HEALTH CARE.** During the course of HIV infection, the patient will be mainly at home and in the community. Luckily, hospitalization is less frequently needed in the treated patient but can be needed intermittently for acute illness. If the disease progresses, the patient can need more care from caregivers and home health nurses. The home health nurse provides physical care, establishes a therapeutic relationship with AIDS patients and their significant others and family/friends, and coordinates care with other health care team members (see “Home Health Hints”).

Caregivers should be assessed for care giver role strain. Support services should be identified, such as community AIDS organizations, Meals on Wheels, respite care services, community mental health, and Internet support groups. Respite care provides the caregiver time away from the caregiver role to reduce stress. When a patient is terminal, comfort care and emotional support for the family are essential. Hospice care can be used at this time.

**Home Health Hints**

- When providing patient care, perform hand hygiene and wash hands frequently, follow standard precautions, and use plastic bags to contain soiled items or clothing.
Evaluation

Patient goals are met if the patient remains free from infection and maintains the desired quality of life and activities as long as possible. If the disease should progress, goals are met if the patient’s needs are met and the patient’s dignity is maintained.

CRITICAL THINKING

Zoe Sampson

1. a. There is no cure for HIV/AIDS; however, medications are available that make an HIV infection a manageable chronic illness. Research continues in the search for a cure.

b. AIDS is diagnosed when CD4+ T-lymphocyte counts are below 200 cells per microliter, or the CD4+ T-lymphocyte percentage is under 14 of total lymphocytes, and/or an opportunistic clinical disease, as defined by the CDC, is present in an HIV-infected person.

c. Yes, your boyfriend could become infected through exposure to your blood or vaginal secretions. You need to learn about preventive measures and discuss them with him. If you have had unprotected sex, he should be tested for HIV.

2. Food handlers must maintain good hand washing and hygiene practices. Discard food that has past the expiration date and dented or swollen cans. Ensure adequate refrigeration and cooking. Control insects and rodents to prevent food contamination. Drink purified bottled water if you live in areas with unsafe drinking water. Use a safe water supply or boil water 1 minute when unsure. Avoid unpasteurized milk, other dairy products, fruit juice, and raw seed sprouts. Avoid raw and undercooked eggs, meats, and seafood.

REVIEW QUESTIONS

1. The nurse would evaluate the patient as understanding modes of HIV transmission if the patient stated that the modes of HIV transmission include which of the following?
   1. Saliva, tears, fecal-oral contamination
   2. Close physical contact involving skin surfaces, mosquito bites
   3. Sharing towels, sharing eating utensils, skin contact
   4. Unprotected sex with HIV-infected partner, contact with infected blood products

2. The nurse is teaching a patient about HIV testing. Place traditional HIV-1 diagnostic tests in the sequential order in which they are performed.
   1. Western blot test
   2. Enzyme-linked immunosorbent assay (ELISA) test
   3. Repeated ELISA test

3. A patient who is newly diagnosed with HIV infection asks what to expect for future health status. The best response for the nurse to give is based on the understanding that HIV disease and AIDS are characterized as which of the following?
   1. An acute disease
   2. A life-ending disease
   3. A chronically managed disease
   4. A disease with remissions and exacerbations

4. The nurse is planning to teach a patient about HIV prevention. What should the nurse include in a teaching plan to prevent HIV infection? Select all that apply.
   1. Recapping of used needles by caregiver permitted.
   2. Abstain from sexual intercourse.
   3. Avoid injection drug use.
   4. Avoid use of male or female condoms.
   5. Plan for autologous blood transfusion.
   6. Test for HIV at time of labor.

5. The nurse is contributing to the teaching plan for a patient with HIV on reducing infection risks. Which of the following should the patient with HIV be taught to do to decrease risk of infections? Select all that apply.
   1. Wash hands before eating.
   2. Wash toothbrush.
   3. Reuse dishes.
   5. Report signs of infection.
   6. Share razor if no visible blood.

6. The nurse would recognize that the patient needs further reinforcement of knowledge if the patient stated that one of the goals of antiretroviral therapy is which of the following?
   1. Reduce the viral load.
   2. Improve survival rates.
   3. Decrease CD4+ T lymphocytes.
   4. Delay the progression of HIV disease.

7. The nurse would recognize that the patient is having a reaction to abacavir sulfate (Ziagen) if which of the following occurred?
   1. Flu-like symptoms
   2. Edema
   3. Abdominal pain
   4. Blurred vision

Answers can be found in Appendix C.

pulse deficit (PULS DEF-ih-sit)
sternotomy (stir-NAW-tuh-mee)
thrill (THRILL)

LEARNING OUTCOMES
1. Identify the normal anatomy of the cardiovascular system.
2. Explain the normal function of the cardiovascular system.
3. List data to collect when caring for a patient with a disorder of the cardiovascular system.
4. Identify diagnostic tests commonly performed to diagnose disorders of the cardiovascular system.
5. Plan nursing care for patients undergoing diagnostic tests for cardiovascular disorders.
6. Describe current therapeutic measures for disorders of the cardiovascular system.
7. Describe preoperative and postoperative care for patients undergoing cardiac surgery.
NORMAL CARDIOVASCULAR SYSTEM ANATOMY AND PHYSIOLOGY

The cardiovascular system consists of the heart, blood, and vessels (including arteries, capillaries, and veins). Its function is to distribute the blood throughout the body.

Heart
Cardiac Structure and Function

LOCATION OF THE HEART. The heart is located in the mediastinum within the thoracic cavity. It is enclosed by three membranes. The outermost is the fibrous pericardium, which forms a loose-fitting pericardial sac around the heart. The second, or middle, layer is the parietal pericardium, a serous membrane that lines the fibrous layer. The third and innermost layer, the visceral pericardium or epicardium, is a serous membrane on the surface of the heart muscle. Between the parietal and visceral layers is serous fluid, which prevents friction as the heart beats.

STRUCTURE OF THE HEART AND CORONARY BLOOD VESSELS. The walls of the four chambers of the heart are made of cardiac muscle (myocardium) and are lined with endocardium, which is smooth epithelial tissue that prevents abnormal clotting. The epithelium also covers the valves of the heart and continues into blood vessels as the endothelium. Coronary circulation provides oxygenated blood throughout the myocardium and returns deoxygenated blood to the right atrium via the coronary sinus. The two main coronary arteries are the first branches of the ascending aorta, just outside the left ventricle (Fig. 21.1).

The superior chambers of the heart are the thin-walled right and left atria, which are separated by the interatrial septum. The lower chambers are the thicker walled right and left ventricles, which are separated by the interventricular septum. Each septum is made of myocardium that forms a common wall between the two chambers.

CORONARY BLOOD FLOW. The right atrium receives deoxygenated blood from the coronary sinus, the upper body by way of the superior vena cava, and from the lower body by way of the inferior vena cava (see Fig. 21.1). This blood flows from the right atrium through the tricuspid valve into the right ventricle. Backflow during ventricular systole (contraction and emptying) is prevented by the tricuspid, or right, atrioventricular (AV) valve (Fig. 21.2). The right ventricle pumps blood through the pulmonary semilunar valve to the lungs by way of the pulmonary artery. The pulmonary semilunar valve prevents backflow of blood into the right ventricle during ventricular diastole (relaxation and filling).

The left atrium receives oxygenated blood from the lungs by way of the four pulmonary veins. This blood flows through the mitral, or left, AV valve (also called the bicuspid valve) into the left ventricle. The mitral valve prevents backflow of blood into the left atrium during ventricular systole. The left ventricle pumps blood through the aortic semilunar valve to the body by way of the aorta. The aortic valve prevents backflow of blood into the left ventricle during ventricular diastole.

The tricuspid and mitral valves consist of three and two cusps, respectively. These cusps, or flaps, are connective tissue covered by endocardium and are anchored to the floor of the ventricle by the chordae tendineae and papillary muscles. The papillary muscles are columns of myocardium that contract along with the rest of the ventricular myocardium. This contraction pulls on the chordae tendineae and prevents hyperextension of the AV valves during ventricular systole (see Fig. 21.2).

Although each ventricle pumps the same amount of blood, the much thicker walls of the left ventricle pump with approximately five times the force of the right ventricle to distribute the blood throughout the body. This difference in force is reflected in the great difference between systemic and pulmonary blood pressure.

Cardiac Conduction Pathway and Cardiac Cycle

The cardiac conduction pathway is the pathway of electrical impulses that generates a heartbeat. The sinoatrial (SA) node in the wall of the right atrium is autorhythmic and depolarizes about 100 times per minute, initiating each heartbeat. (While at rest, parasympathetic fibers dominate and slow the SA node to about 75 beats per minute.) For this reason, the SA node is called the pacemaker, and a normal heartbeat is called a normal sinus rhythm. From the SA node, impulses travel on a specific path (Fig. 21.3). If the SA node becomes non-functional, the AV node can initiate each heartbeat, but at a slower rate of 40 to 60 beats per minute. The bundle of His is capable of generating the beat of the ventricles, but at the much slower rate of about 20 to 35 beats per minute.

A cardiac cycle is the sequence of mechanical events that occurs during each heartbeat. Simply stated, the two atria contract simultaneously, followed by the simultaneous contraction of the two ventricles (a fraction of a second later). The contraction (emptying), or systole, of each set of chambers is followed by relaxation (filling), or diastole, of the same set of chambers.

The events of the cardiac cycle create the normal heart sounds. The first of the two major sounds (the “lubb” of “lubb-dupp”) is caused by the closure of the AV valves during ventricular systole. The second sound is created by the closure of the aortic and pulmonary semilunar valves.

Cardiac Output

Cardiac output is the amount of blood ejected from the left ventricle in 1 minute (the right ventricle pumps a similar amount). It is determined by multiplying stroke volume by heart rate. Stroke volume is the amount of blood ejected by a ventricle in one contraction and averages 60 to 80 mL/beat. With an average resting heart rate of 75 beats per minute, average resting cardiac output is 5 to 6 L (approximately the total blood volume of an individual that is pumped within 1 minute). Ejection fraction is a measure of ventricular efficiency and is normally 55% to 70% of the total amount of blood within the left ventricle that is ejected with each heartbeat.
During exercise, venous return increases and stretches the ventricular myocardium, which in response contracts more forcefully. This is known as Starling’s law of the heart, and the result is an increase in stroke volume. More blood is pumped with each beat, and at the same time, the heart rate increases, causing cardiac output to increase by as much as four times the resting level, or more for fit athletes.

**Regulation of Heart Rate**

The heart generates its own electrical impulse, which begins at the SA node. The nervous system, however, can change the heart rate in response to environmental circumstances. In the brain, the medulla oblongata receives sensory input and alters heart function (Fig. 21.4).

**Hormones and the Heart**

The hormone epinephrine, secreted by the adrenal medulla in stressful situations, is sympathomimetic in that it increases the heart rate and force of contraction and dilates the coronary vessels. This in turn increases cardiac output and systolic blood pressure.

Aldosterone, a hormone produced by the adrenal cortex, is important for cardiac function because it helps regulate blood levels of sodium and potassium, both of which are needed for the electrical activity of the myocardium. The blood level of potassium is especially critical because even a small deviation impairs the rhythmic contractions of the heart.

The atria of the heart secrete a hormone of their own called atrial natriuretic peptide or atrial natriuretic hormone. As its name suggests, atrial natriuretic peptide increases the excretion of sodium by the kidneys by inhibiting secretion of aldosterone by the adrenal cortex. Atrial natriuretic peptide is secreted when a higher blood pressure or greater blood volume stretches the walls of the atria. The loss of sodium is accompanied by the increase loss of water in urine, which decreases blood volume and therefore blood pressure as well.

**Blood Vessels**

**Arteries and Veins**

Arteries and arterioles carry blood from the heart to capillaries. Their walls are relatively thick and consist of three
layers. Arteries carry blood under high pressure, and the outer layer of fibrous connective tissue prevents rupture of the artery. The middle layer of smooth muscle and elastic connective tissue contributes to the maintenance of normal blood pressure, especially diastolic blood pressure, by changing the diameter of the artery. The diameter of arteries is regulated primarily by the sympathetic division of the autonomic nervous system. By use of the smooth muscle, the arteries can also alter where the greatest volume of blood is directed. The inner layer or lining of the artery is simple squamous epithelium, called endothelium, which is very smooth to prevent abnormal clotting.

Veins and venules carry blood from capillaries to the heart. Their walls are relatively thin because they have less smooth muscle than arteries. Sympathetic impulses can bring about extensive constriction of veins, however, and this becomes important in situations such as severe hemorrhage. The lining of veins is, like arteries, endothelium that prevents abnormal clotting; at intervals it is folded into valves to prevent backflow of blood. Valves are most numerous in the veins of the extremities, especially the legs, where blood must return to the heart against the force of gravity.

**Capillaries**

Capillaries carry blood from arterioles to venules and form extensive networks in most tissues. The exceptions are cartilage, covering/lining epithelia, and the lens and cornea of the eye. Capillary walls, a continuation of the lining of arteries and veins, are one cell thick to permit the exchanges of gases, nutrients, and waste products between the blood and tissues (Fig. 21.5). Blood flow through a capillary network is regulated by a precapillary sphincter, a smooth muscle fiber ring.

---

that contracts or relaxes in response to tissue needs. In an active tissue such as exercising skeletal muscle, for example, the rapid oxygen uptake and carbon dioxide production cause dilation of the precapillary sphincters to increase blood flow. At the same time, precapillary sphincters in less active tissues constrict to reduce blood flow. This is important because the body does not have enough blood to fill all of the capillaries at once; the fixed volume must constantly be shunted or redirected to where it is needed most.

Exchange between blood and tissue fluids occurs primarily due to diffusion and/or filtration at the capillaries. Diffusion is important to gas exchange. Filtration is a vital mechanism for homeostasis of extracellular fluids. Some of this tissue fluid returns to the capillaries, and some is collected in lymph capillaries. Lymph is returned to the blood by lymph vessels. Should blood pressure within the capillaries increase, more tissue fluid than usual is formed, too much for the lymph vessels to collect. This may result in tissue swelling, called edema.

**Blood Pressure**

Blood pressure is the force of the blood against the walls of the blood vessels and is measured in millimeters of mercury (mm Hg), systolic over diastolic. The normal average of systemic arterial pressure is 120/80 mm Hg. Blood pressure decreases in the arterioles and capillaries, and the systolic and diastolic pressures merge into one pressure. As blood enters the veins, blood pressure decreases further and approaches zero as it flows into the right ventricle. As mentioned previously, the blood pressure in the capillaries is of great importance, and normal blood pressure is high enough to permit filtration for nourishment of tissues but low enough to prevent rupture.

The arterioles (and veins during increased sympathetic stimulation) are usually in a state of slight constriction that helps to maintain normal blood pressure, especially diastolic pressure. This is called peripheral resistance; it is regulated...
by the vasomotor center in the medulla, which receives input via the glossopharyngeal and vagus nerves.

Blood pressure is also affected by many other factors. If heart rate and force increase, blood pressure increases within limits. If the heart is beating very fast, the ventricles are not filled before the y contract, cardiac output decreases, and blood pressure drops. The strength of the heart’s contractions depends on adequate venous return, which is the amount of blood that flows into the atria. Decreased venous return results in weaker contractions.

Venous return depends on several factors: constriction of the veins to reduce pooling, the skeletal muscle pumping to squeeze the deep v eins of the le gs, and the diaphragm’ s downward pressure during inhalation to compress the abdominal veins as the thoracic veins are decompressed. The valves in the veins prevent backflow of blood and thus contribute to the return of blood to the heart.

The elasticity of the large arteries also contributes to normal blood pressure. When the left ventricle contracts, the blood stretches the elastic walls of the large arteries, which absorb some of the force. When the left ventricle relaxes, the arterial walls recoil, exerting pressure on the blood. Normal elasticity, therefore, lowers systolic pressure, raises diastolic pressure, and maintains normal pulse pressure. Pulse pressure is the difference between the systolic and diastolic pressures. The usual ratio of systolic to diastolic to pulse pressure is 3:2:1.

**Renin-Angiotensin-Aldosterone Mechanism**

The kidneys are of great importance in the regulation of blood pressure. If blood flow through the kidneys decreases, renal filtration decreases and urinary output decreases to preserve blood volume. Decreased blood pressure stimulates the kidneys to secrete renin, which initiates the renin-angiotensin-aldosterone mechanism, raising blood pressure (Fig. 21.6).

Other hormones that affect blood pressure include those of the adrenal medulla, norepinephrine and epinephrine, which increase cardiac output and cause vasoconstriction in skin and viscera. Antidiuretic hormone, released from the posterior pituitary, directly increases water reabsorption by the kidneys, thus increasing blood volume and blood pressure. Atrial natriuretic peptide, secreted by the atria of the heart, inhibits aldosterone secretion and thereby increases renal excretion of sodium ions and water, which decreases blood volume and subsequently blood pressure.

**Circuits of Circulation**

The two circuits of circulation are pulmonary and systemic (see Fig. 21.2). Pulmonary circulation begins at the right ventricle, which pumps deoxygenated blood toward the lungs for gas exchange at the alveoli. Oxygenated blood returns to the left atrium by way of the pulmonary v eins. Low pressure in the pulmonary capillaries prevents filtration in pulmonary capillaries, keeping tissue fluid from accumulating in the alveoli of the lungs, which can otherwise result in pulmonary edema.

Systemic circulation begins in the left ventricle, pumping oxygenated blood into the aorta, the many branches of which eventually give rise to capillaries within the tissues. Deoxy- genated blood returns to the right atrium by way of the superior and inferior vena cava and the coronary sinus. The hepatic portal circulation is a special part of the systemic circulation in which blood from the capillaries of the digestive organs and spleen flows through the portal vein and into the sinusoids in the liver before returning to the heart. This pathway permits the liver to regulate the blood levels of nutrients such as glucose, amino acids, and iron and to remove potential toxins such as alcohol or medications from circulation.

**Aging and the Cardiovascular System**

The aging of blood vessels, especially arteries, is believed to begin in childhood, although the effects are not apparent until later in life (Fig. 21.7). **Atherosclerosis** is the deposition of lipids in the walls of arteries over a period of years. The deposited lipids can narrow the arteries’ lumens and form rough surfaces that may stimulate intra vascular clot formation. Atherosclerosis decreases blood flow to the affected organ. With age, the heart muscle becomes less efficient, and maximum cardiac output and heart rate both decrease, although resting levels may be more than sufficient (“Gerontological Issues”). Valves may become thickened by fibrosis, leading to heart murmurs.
In 2010, according to U.S. statistics of the American Heart Association (AHA, 2014), about one in six deaths were due to coronary heart disease; about 33% of United States adults over 19 years of age have hypertension per data from 2007 to 2010, and hypertension occurrence in African American adults is the highest in the world. For more information on cardiovascular disease statistics, visit www.americanheart.org.

In women, the greatest cause of death is cardiovascular disease. A movement called Go Red for Women gives women encouragement and tools to prevent cardiovascular disease and live healthy. For more information on Go Red for Women, visit www.goredforwomen.org.

Lifestyle plays a major role in risk factors for cardiovascular disease. The AHA recommends improving cardiovascular health by not smoking, exercising, following a healthy diet, and maintaining normal blood pressure, blood glucose, total cholesterol levels, and weight. Exercise is essential for everyone, especially children, because Americans continue to be sedentary and eat excess calories.

**NURSING ASSESSMENT OF THE CARDIOVASCULAR SYSTEM**

Nursing assessment of the cardiovascular system includes a patient health history and physical examination (“Gerontological Issues”). If the patient is experiencing an acute problem, focus on the most serious signs and symptoms and physical data until he or she is stabilized (Table 21.1). In-depth data collection can be completed when the patient is stable.

Health History

To understand a patient's cardiovascular problems, ask about past and current symptoms, medications, use of recreational drugs, surgeries, treatments, and risk factors such as diet, activity, tobacco use, and recent stressors. Data collection includes asking questions in the WHAT'S UP? format: where it is, how it feels, aggravating and alleviating factors, timing, severity, useful data for associated symptoms, and perception by the patient of the problem.

The health history helps determine the cause of the symptom. For example, shortness of breath can be the result of heart failure or chronic obstructive pulmonary disease (COPD). With cardiovascular problems, data collection focuses on the areas listed in Table 21.2.

Medical History

Previous medical records can provide objective patient data that can be supplemented with patient responses. Childhood illnesses that can lead to heart disease, such as rheumatic fever or scarlet fever, are noted. Other conditions noted include pulmonary disease, hypertension, kidney disease, cerebral vascular accident or brain attack, transient ischemic (restricted blood flow) attack, renal disease, anemia, streptococcal sore throat, and...
congenital heart disease, thrombophlebitis, and alcoholism. Patient allergies, previous hospitalizations, and surgeries are documented. Baseline diagnostic tests are helpful for comparison with current tests. Functional limitations that are related to cardiovascular problems, such as difficulty performing activities of daily living (ADLs), walking, climbing stairs, or completing household tasks, are also assessed.

**Medication**

Use of prescription drugs, over-the-counter medications such as aspirin that can prolong clotting time, and recreational drugs is noted. Patient’s understanding of medications (name, dosage, reason for taking, last dose, and length of use) is documented.

**Family History**

A family history (parents, siblings, and grandparents) of cardiovascular conditions is noted because many cardiac problems are hereditary. For example, those who have had a parent die of sudden cardiac death before age 60 are at increased risk for sudden cardiac death.

**Health Promotion**

Risk factors such as diet, activity, tobacco use, and recent stressors for the patient are noted. The patient’s health promotion activities are explored, especially for risk factors that are modifiable with changes in lifestyle.

**Physical Examination**

The patient’s general appearance is observed. The patient’s level of consciousness, which is an indicator of oxygenation of the brain, is noted. Height, weight, and vital signs are recorded.

**Blood Pressure**

Normal blood pressure is considered less than 120/80 (see Chapter 22). Readings in both arms are done for comparison (Box 21-1). A difference in the readings is reported to the HCP. The arm with the higher reading is used for ongoing measurements. If necessary, blood pressure may be measured in the leg using a larger blood pressure cuff. The reading in the leg is normally 10 mm Hg higher than in the arm (see “Evidence-Based Practice”).

**EVIDENCE-BASED PRACTICE**

Clinical Question

Is blood pressure self-measurement at home more accurate for hypertension control and predictive of the risk of cardiovascular events than office blood pressure measurement?

Evidence

In a meta-analysis of studies conducted across a variety of populations, it was shown that home blood pressure recordings were a stronger predictor of long-term cardiovascular events than office blood pressure measurements. Home blood pressure monitoring overcomes the “white
ORTHOSTATIC BLOOD PRESSURE. Measurements are taken with the patient lying, sitting, and standing to detect abnormal variations with postural changes. When the patient sits or stands, a drop in the systolic pressure of up to 15 mm Hg and either a drop or slight increase in the diastolic pressure of 3 to 10 mm Hg is normal. In response to the drop in blood pressure, the pulse increases 15 to 20 beats per minute to maintain cardiac output. Orthostatic hypotension (postural hypotension), is a drop in systolic blood pressure greater than 15 mm Hg, a drop or slight increase in the diastolic blood pressure greater than 10 mm Hg, and an increase in heart rate greater than 20 beats per minute in response to the drop in blood pressure. It indicates a problem that should be investigated by the health care provider (HCP) (Box 21-2). The patient often reports lightheadedness or syncope because the drop in blood pressure decreases the amount of oxygen-rich blood traveling to the brain. Factors that may cause orthostatic hypotension include deficient fluid volume, diuretics, analgesics, and pain.

Pulses

The apical pulse is auscultated for 1 minute to assess rate and rhythm. Normal heart rate is 60 to 100 beats per minute. In athletic people, the heart rate is often slower, around 50 beats per minute, because the well-conditioned heart pumps more efficiently. Apical pulse rhythm is documented as regular or irregular. The apical rate can be compared with the radial rate to assess equality. If there are fewer radial beats than apical beats, a pulse deficit exists and should be reported to the HCP.

Arterial pulses are palpated for volume and pressure quality. They are palpated bilaterally and compared for equality. A normal vessel feels soft and springy. A sclerotic vessel feels stiff. The quality of the pulses is described on a four-point scale as follows: 0 is absent; 1+ is weak, thready; 2+ is normal; and 3+ is bounding. An absent pulse is not palpable. A thready pulse is one that disappears when slight pressure is applied and returns when the pressure is removed. The normal pulse is easily palpable. The bounding pulse is strong and present even when slight pressure is applied. When the normal vessel is palpated, a tapping is felt. In the abnormal vessel that has a bulging or narrowed wall, a vibration is felt, which is called a thrill. When auscultating an abnormal vessel, a humming is heard that is caused by the turbulent blood flow through the vessel. This is referred to as a bruit.

BE SAFE!

Anticipate potential drops in blood pressure with position changes. Orthostatic hypotension can be found in patients of any age but is most commonly found in the older patient. The blood pressure drop increases the risk of fainting and falling. Use fall precautions such as a walking belt or two-person assist for patients at risk of or with orthostatic hypotension.
Inspection

During the health history, inspection begins by noting shortness of breath when the patient speaks or moves. The patient’s skin is noted for oxygenation status through the color of skin, mucous membranes, lips, earlobes, and nailbeds. Pallor may indicate anemia or lack of arterial blood flow. Cyanosis shows an oxygen distribution deficiency. A reddish brown discoloration (rubor) found in the lower extremities occurs from decreased arterial blood flow. A brown discoloration and cyanosis when the extremity is dependent may be seen in the presence of venous blood flow problems. Hair distribution on the extremities is observed. Decreased hair distribution, thick, brittle nails, and shiny, taut, dry skin occur from reduced arterial blood flow. Venous blood return is assessed by inspecting extremities for varicose veins, stasis ulcers, or scars around the ankles and signs of thrombophlebitis such as swelling, redness, or a hard, tender vein.

The patient’s internal and external jugular neck veins are observed for distention in a 45- to 90-degree upright position. Normally, the veins are not visible in this position. Distention indicates an increase in the venous volume, often caused by right-sided heart failure.

Capillary refill time is 3 seconds or less and indicates arterial blood flow to the extremities. The patient’s nailbed is briefly squeezed, causing blanching, and then released. The time that it takes for the color to return to the nailbed after release of the squeezing pressure is the capillary refill time. Longer times indicate anemia or a decrease in blood flow to the extremity.

Clubbing of the nailbeds occurs from oxygen deficiency over time. It is often caused by congenital heart defects or the long-term use of tobacco. The distal ends of the fingers and toes swell and appear clublike. With clubbing, the normal 160-degree angle formed between the base of the nail and the skin is lost, causing the nail to be flat (Fig. 21.8). Later, the nail base elevates, the angle exceeds 180 degrees, and the nail feels spongy when squeezed. To check for this, touch your index fingers together at the nailbeds and first joint. Look through the space created at the nailbeds. Do you see a diamond? If so, that is normal. If there is not a diamond, this indicates the nailbeds are clubbed and therefore filling that space. This should be reported to an HCP for follow-up.

Respirations

The rate and ease of respirations are observed. Breath sounds are auscultated. Sputum characteristics such as amount, color, and consistency are noted. Pink, frothy sputum is an indicator of acute heart failure. A dry cough can occur from the irritation caused by the lung congestion resulting from heart failure.

Box 21-2 Orthostatic Hypotension Assessment

To assess orthostatic hypotension:
1. Explain procedure to patient; determine if patient can safely stand.
2. Patient should not exercise, eat, or smoke 30 minutes before readings.
3. Have patient lie flat in bed at least 5 minutes before readings.
4. Use correct size blood pressure cuff.
5. Patient should not talk during readings and should sit up with legs uncrossed while sitting.
6. Take patient’s lying blood pressure and heart rate.
7. Assist patient to sitting position. Ask if dizzy or light-headed with each position change. If yes, ensure safety from fainting or falling. A gait or walking belt can be used. With any position change, if patient experiences additional symptoms with the dizziness and decreased blood pressure and increased heart rate, assist the patient to lie down, take blood pressure, and notify the HCP. Consider the possible cause of the orthostatic hypotension (hemorrhaging, dehydration, diuretics) to plan patient care.
8. Wait 3 minutes, and then take patient’s sitting blood pressure and heart rate. If patient is dizzy or light-headed, continue sitting position for 5 minutes if tolerated. Do not attempt to bring the patient to standing. Repeat sitting blood pressure. If blood pressure has increased and patient is no longer dizzy, assist patient to stand.
9. Assist patient to stand and take blood pressure and pulse immediately. Then take again in 3 minutes. If blood pressure drops and patient is dizzy or light-headed, do not attempt to ambulate patient.
10. Document all heart rate and blood pressure measurements, including extremity used and patient position when reading was obtained (e.g., right arm: lying 132/78 mm Hg, sitting 118/68 mm Hg, standing 110/60 mm Hg). Also document patient tolerance, symptoms, and nursing interventions if symptomatic.
11. Report abnormal findings to HCP.

LEARNING TIP

Six Ps characterize peripheral vascular disease:
- Pain
- Paresthesia (decreased sensation)
- Pallor
- Paralysis
- Pulselessness
- Poikilothermia

Respirations

The rate and ease of respirations are observed. Breath sounds are auscultated. Sputum characteristics such as amount, color, and consistency are noted. Pink, frothy sputum is an indicator of acute heart failure. A dry cough can occur from the irritation caused by the lung congestion resulting from heart failure.
Palpation

In addition to palpating the arteries, the thorax can be palpated at the point of maximum impulse. The point of maximum impulse is palpated by placing the right hand over the apex of the heart. If palpable, a thrust is felt when the ventricle contracts. An enlarged heart may shift the pulse of maximum impulse to the left of the midclavicular line.

The temperature of the extremities is palpated bilaterally for comparison. Palpation begins proximally and moves distally along the extremity. In areas of decreased arterial blood flow, the ischemic area feels cooler than the rest of the body because it is blood that warms the body. In the absence of sufficient arterial blood flow, the area becomes the temperature of the environment (poikilothermy). A warm or hot extremity indicates a venous blood flow problem.

Edema is palpated in the lower extremities or dependent areas such as the sacrum for the supine patient (Fig. 21.9). Edema can occur from right-sided heart failure, gravity, or altered venous blood return. The nurse assesses the severity of the edema by pressing with a finger for 5 seconds over a bone, the medial malleolus or tibia, in the area of edema. If the finger imprint or indentation remains, the edema is pitting. Measuring the leg circumference is an accurate method for monitoring the edema.

Homans’ sign is an assessment for venous thrombosis; however, in less than 50% of patients with thrombosis, the test is not positive. A positive Homans’ sign is pain in the patient’s calf or behind the knee when the foot is quickly dorsiflexed with the knee in a slightly flexed position (Fig. 21.10). Homans’ sign should not be performed if a positive diagnosis of thrombosis has been made because a clot could be dislodged with the movement.

Auscultation

Normal heart sounds are produced by the closing of the heart valves. Sound in blood-flowing vessels is transmitted in the direction of the blood flow. The first heart sound (S1) is heard at the beginning of systole as “lubb” when the tricuspid and mitral (AV) valves close (Fig. 21.11). The second heart sound (S2) is heard at the start of diastole as “dupp” when the aortic and pulmonic semilunar valves close. The diaphragm of the stethoscope is used to hear the high-pitched sounds of S1 and S2. Normally, no other sounds are heard between S1 and S2. With the bell of the stethoscope placed at the apex, a third heart sound (S3) or a fourth heart sound (S4) may be heard. Having patients lean forward or lie on their left side can make the heart

- WORD BUILDING

FIGURE 21.8 Clubbing of the fingers.

FIGURE 21.9 Pitting edema. Application of pressure over a bony area displaces the excess fluid, leaving an indentation or pit.

FIGURE 21.10 Assessment of Homans’ sign for venous thrombosis. The foot is quickly dorsiflexed with the knee flexed. Calf or knee pain is noted. This assessment should not be performed if a positive diagnosis of thrombosis has been made.
sounds easier to hear by bringing the area of the heart where the sound may be heard closer to the chest wall. The S3 heart sound is normal for children and younger adults. It sounds like a gallop and is a low-pitched sound heard early in diastole. In older adults, S3 may be heard with left-sided heart failure, fluid volume overload, and mitral valve regurgitation. The S4 heart sound is also a low-pitched sound, similar to a gallop but heard late in diastole. It occurs with hypertension, coronary artery disease, and pulmonary stenosis.

Murmurs are caused by a narrowed valve opening or a valve that does not close tightly. A murmur is a prolonged, swishing sound that ranges in intensity from faint to very loud.

A pericardial friction rub occurs from inflammation of the pericardium. The intensity of a rub can range from faint to loud enough to be audible without a stethoscope. A rub has a grating sound like sandpaper being rubbed together that occurs when the pericardial surfaces rub together during a heartbeat. (See the Learning Tip on pericardial friction rub in Chapter 23.) Having the patient sit and lean forward allows a rub to be heard more clearly. The rub is best heard to the left of the sternum using the diaphragm of the stethoscope. A pericardial friction rub may occur after a MI or chest trauma.

CRITICAL THINKING

Mrs. Smith

Mrs. Smith, age 78, baseline weight 162 pounds, is admitted to the hospital with shortness of breath. Initial assessment findings are BP 152/88 mm Hg, pulse 104 beats per minute, respirations 26 per minute, temperature 99.4°F (37.2°C), shortness of breath at rest that increases with activity, ankles swollen, heart tones distant, nailbeds pale, no pain, has not eaten well for 2 weeks, 6-pound weight gain in 1 week, sleeps on three pillows, neck veins visible bilaterally. A diagnosis of acute MI with heart failure is made by her HCP.

1. Why might Mrs. Smith not be having chest pain with a diagnosis of acute MI?
2. How should swollen ankles be assessed to provide complete and measurable data?
3. What should be documented for the assessment performed on the swollen ankles and how should the assessment findings be documented?
4. How should the assessment findings be documented for the additional symptoms Mrs. Smith has?
5. What is Mrs. Smith’s weight in kilograms?
6. What health care team members might provide collaborative care for Mrs. Smith?

Suggested answers are at the end of the chapter.

Computed Tomography

Computed tomography (CT) for calcium scoring of calcified plaque (the body deposits calcium to harden plaques, which are not normally found in the coronary arteries) in the coronary arteries can be done.

CT angiography (view body blood vessels) and coronary CT angiography (view coronary arteries) use an iodine contrast agent. Patient kidney function (glomerular filtration rate, creatinine) must be checked before the test to help prevent contrast-induced nephropathy (Chapter 36).

Cardiac Magnetic Resonance Imaging and Angiography

Two- or three-dimensional still or moving images of the beating heart are produced with magnetic resonance imaging (MRI). Cardiac MRI is useful for identifying ischemia and heart damage as well as other conditions affecting the heart. For magnetic resonance angiography, a non–iodine-based
contrast, gadolinium-DTPA, may or may not be used to view the blood vessels.

**Electrocardiogram**

The electrocardiogram (ECG) records electrical activity of the heart in various views. Abnormalities related to conduction, rate, rhythm, heart chamber enlargement, myocardial ischemia, MI, and electrolyte imbalances may be reflected on an ECG. When an ECG is requested, information that aids in its interpretation is provided, including the patient’s sex, age, height, weight, blood pressure, and cardiac medications. There is no special preparation for the ECG, which is painless.

To obtain an ECG, electrodes are placed on the skin to transmit electrical impulses to the ECG machine for recording. The electrical impulses from the heart appear as waves on graph paper. One view of the heart using a combination of the electrodes to obtain the view is called a lead. The standard 12-lead ECG, using a combination of the electrodes, provides 12 views of the heart. Eighteen-lead ECGs can also be done.

**Signal-Averaged ECG.** The signal-averaged ECG is used to diagnose whether a patient is at risk of developing ventricular tachycardia and possible sudden death. A computer records low-level signals not detected by a regular ECG. These electrical signals, referred to as late potentials, occur in the end of the QRS wave and into the ST segment. These electrical signals, referred to as late potentials, occur in the end of the QRS wave and into the ST segment. They are recorded by a computer and interpreted by an HCP.

**Holter Monitoring (Ambulatory Electrocardiogram).** A Holter monitor, which weighs 2 pounds, continuously records an ECG in one lead for up to 48 hours as a patient goes about his or her daily activities. The patient wears loose-fitting clothing and may only sponge bathe while wearing the monitor. The patient records a diary of activities and symptoms and pushes the event button if symptoms occur. Symptoms are documented for later correlation with the ECG recordings. Dysrhythmias or myocardial ischemia that occurs infrequently can be detected. Recordings are scanned by a computer and interpreted by an HCP.

**Doppler Ultrasound**

In a Doppler ultrasound test, sound waves bounce off moving blood cells and return a sound frequency in relationship to the amount of blood flow. With decreased blood flow the sounds are reduced. This test requires no patient preparation, takes about 20 minutes to complete, and is painless.

**Echocardiogram**

An echocardiogram is an ultrasound test that records the motion of the heart structures, including the valves and chambers, as well as the heart size, shape, and position. Three-dimensional images of the heart and four-dimensional (real-time) heart imaging is possible. Color Doppler can record blood flow through the heart valves. No preparation is required. This test transmits ultrasonic sound waves across the chest wall (transthoracic) and through lung and rib tissue into the heart so that the returned echoes can be recorded. An ECG is recorded at the same time.

**Strain Echocardiogram.** A comprehensive assessment of the function of the heart muscle (myocardium) is obtained with a strain echocardiogram. It shows changes in the shape of the heart (deformation). It is used for heart failure, cardiomyopathy, to guide treatment, or evaluate cardiac surgery or transplant.

**Exercise Stress Echocardiogram.** Coronary artery disease is diagnosed during exercise-induced cardiac ischemia by detecting cardiac wall motion abnormalities. If the patient is unable to exercise (treadmill, stationary bike), giving dobutamine for a dobutamine stress echocardiography simulates exercise while the echocardiogram is done.

**Transesophageal Echocardiogram.** A transesophageal echocardiogram (TEE) provides a clearer picture than transthoracic echocardiography. Three-dimensional images of the heart and four-dimensional (real-time heart imaging) images are also possible with TEE. Images are produced by using a transducer on a probe that is placed in the esophagus. The images are clearer because lung and rib tissue does not have to be penetrated by the sound waves. The physician controls the position of the probe and takes pictures as it travels within the esophagus. Patients take nothing by mouth (NPO) for about 6 hours before the test, receive a sedative, and have their throats locally anesthetized.

**Cardiac Stress Test**

The exercise stress test measures cardiac function or peripheral vascular disease during a defined exercise protocol (Fig. 21.13). It shows the heart’s response to increased oxygen needs. Before the test, patients are given an explanation of the test and told not to smoke, eat, or drink for 2 to 4 hours before the test. They are also instructed to wear comfortable walking shoes, a loose top, and, for women, a supportive bra. Before the test, baseline vital signs are obtained.

Then, while the patient exercises on a treadmill, on a stationary bicycle, or by climbing stairs, vital signs, oxygen saturation, skin temperature, physical appearance, chest pain, and ECG are monitored to help ensure patient safety. The test is completed when the patient reaches his or her peak heart rate.
rate (patient’s age subtracted from 220), experiences chest pain, is unable to exercise further, or develops vital sign or ECG changes. Vital signs and ECG continue to be monitored after the test until they return to baseline. After the test, patients should rest and wait to eat. They should also avoid eating or drinking stimulants such as caffeine and temperature extremes such as going out into cold weather for a few hours after the test.

The cardiac stress test is used to evaluate coronary artery disease. It aids in diagnosing ischemic heart disease, the cause of chest pain, and dysrhythmias. The functional capacity of the heart can also be measured after a cardiac event or to plan a physical fitness or rehabilitation program.

**Peripheral Vascular Stress Test**

In a peripheral vascular stress test, the patient walks for 5 minutes at 1.5 miles per hour on the treadmill. At certain intervals, pulse volume measurements are taken, including baseline resting, during the test, and final resting after the test. This test assesses response to activity. If intermittent claudication (pain in the legs with activity) occurs, the test is stopped.

**Arterial Stiffness Index**

Stiffness of the brachial artery is measured to determine atherosclerosis and cardiovascular disease risk. The brachial artery correlates with the coronary arteries in regard to the extent of atherosclerosis. The arterial stiffness index test is done with a device that has a blood pressure cuff hooked to a computer that maps the waveforms during the blood pressure reading.

**Tilt Table Test**

The tilt table test is used to help diagnose the cause of syncope (fainting spells). Heart rate and blood pressure are monitored during a change in position from lying down to standing up.

**Nuclear Radioisotope Imaging**

For nuclear radioisotope imaging, small amounts of radioisotopes are given intravenously (IV). The patient is then scanned with a gamma camera to produce a radionuclide image. Radiation exposure is similar to that of other x-ray examinations. These tests can provide information about myocardial ischemia or infarction, cardiac blood flow, and ventricle size and motion.

**Thallium Imaging**

Thallium-201, a radioactive analog of potassium, is used to detect impaired myocardial perfusion. It is injected IV and muscle cells absorb it. After 10 to 15 minutes, the heart is scanned to see where the thallium has concentrated. Four hours later, the scan is repeated to look for changes. Healthy myocardial cells with good blood flow take up the thallium. Areas in which the thallium is not seen are referred to as cold spots and indicate ischemia or infarction. The patency of a coronary artery graft may also be assessed with this test. This test is used often because the short half-life of thallium results in lower radiation exposure.

Exercise testing may be combined with thallium injection to detect blood flow changes with activity and after rest. The patient exercises and about 2 minutes before stopping is given thallium. Scans are taken immediately and again in 2 to 4 hours. Cold spots on initial images indicate ischemia. If the cold spots are gone in later images, exercise-induced ischemia is present. If the cold spots are still present in later images, they show scarred areas.

If patients are unable to participate in exercise for the thallium stress test, dipyridamole (Persantine) or adenosine, coronary vasodilators, can be given. These drugs simulate the increased blood flow to healthy myocardial cells that occurs with exercise.

**Technetium Pyrophosphate Scan**

Technetium-99m pyrophosphate is injected for this test. Areas of ischemia or myocardial cell damage take up the radioisotope, and when scanned these areas appear as hot spots. Acute MI size and location can be detected, but old MIs cannot be detected.

**Technetium-99m Sestamibi**

For this test, technetium-99m sestamibi is given IV and the patient is scanned 1.5 to 2 hours later. Areas of myocardial cell damage take up the radioisotope, and when scanned these areas appear as hot spots.

**Multiple-Gated Acquisition Scan**

In a multiple-gated acquisition scan, technetium-99m pertechnetate is injected IV and remains in the bloodstream; it is not
taken up by myocardial cells. A camera follows the flow of the radioactivity, which shows ventricular function and wall motion and the ejection fraction of the heart.

**Positron Emission Tomography**

Positron emission tomography (PET) shows myocardial perfusion and viability with three-dimensional images. Nitrogen-13 ammonia is injected IV first and then scanned to show myocardial perfusion. Next, fluoro-18-deoxyglucose is given IV and then scanned to show myocardial metabolic function. If ischemia or heart damage is present, the two scans are different. For example, in ischemia of viable cells, blood flow is decreased but metabolism elevated. Treatment to increase blood flow improves cardiac function in this case. Before the test, the patient’s blood glucose should be in the normal range, and caffeine and tobacco should be avoided for 4 hours before the test.

**BE SAFE!**

Improve the accuracy of patient identification:

- Use at least two ways to identify patients when providing care, treatment, and services. For example, use the patient’s name and date of birth.
- Use two identifiers and label sample collection containers in the presence of the patient.
- Conduct a preprocedure verification process. Implement a preprocedure process to verify the correct procedure, for the correct patient, at the correct site (2014 National Patient Safety Goals, © The Joint Commission, 2013. Reprinted with permission.).

**Blood Studies**

**Blood Lipids**

Lipids include triglycerides, cholesterol, and phospholipids. Lipoproteins carry these lipids attached to proteins. Triglycerides are found in very low-density lipoproteins (VLDLs). Cholesterol is mainly found in low-density lipoproteins (LDLs). High-density lipoproteins (HDLs) are a mixture of one-half protein and one-half phospholipids and cholesterol.

A lipid profile can screen for increased risk of coronary artery disease. For more information, visit [www.nhlbi.nih.gov/guidelines/cholesterol/atglance.pdf](http://www.nhlbi.nih.gov/guidelines/cholesterol/atglance.pdf). Patients must fast for 12 hours and avoid alcohol for 24 hours before the test. Water is not withheld. High levels of LDLs are linked to an increase in coronary artery disease because the y circulate cholesterol in the arteries. HDLs play a protective role against coronary artery disease because they carry cholesterol to the liver to be metabolized. Controlling lipids is important in reducing coronary artery disease (“Cultural Considerations”).

**C-Reactive Protein**

C-reactive protein is an acute-phase protein that increases during the inflammatory process. A highly sensitive C-reactive protein (hs-CRP) test can predict heart attack risk. With elevated hs-CRP levels, nurses have the opportunity to help patients understand and reduce cardiac risk factors.

**Homocysteine**

Homocysteine is an amino acid in the blood that may damage the lining of arteries and promote blood clots. Elevated levels are associated with increased cardiovascular disease risk. Folic acid, vitamin B₆, and vitamin B₁₂ break down homocysteine. Adequate dietary intake of green leafy vegetables and grains fortified with folic acid, as well as vitamin B, can help reduce homocysteine levels.

**Cardiac Biomarkers**

Proteins and enzymes released into the blood by damaged cardiac cells are known as cardiac biomarkers. These biomarkers help identify whether a patient is having or has had a recent MI.

**CREATINE KINASE.** Creatine kinase CK is an enzyme found in the brain, skeletal muscle, and heart muscle. Isoenzymes of creatine kinase contained in these tissues are CK-BB (brain), CK-MM (skeletal muscle), and CK-MB (heart muscle). CK-MB helps diagnose a MI because its level rises within 4 to 6 hours after cardiac cells are damaged, peaks in 12 to 18 hours, and returns to normal in 24 to 36 hours. Invasive procedures such as IV and intramuscular (IM) injections are avoided before drawing the first creatine kinase to prevent elevation in the creatine kinase levels from cell trauma caused by the procedure. Medications are often given IV rather than IM to prevent contributing to this elevation.

**Cultural Considerations**

Among French Canadians, familial chylomicronemia (hypercholesterolemia type I), an autosomal recessive disorder, occurs with the highest frequency worldwide. Familial chylomicronemia can lead to coronary thrombosis. Thus, the nurse can improve the health of French Canadians by encouraging early diagnostic workups for familial chylomicronemia and encouraging healthful lifestyles.
**CARDIAC TROPONIN.** Cardiac muscle contains proteins called troponin I and troponin T, which control the muscle fibers that contract or squeeze the heart muscle. They detect minor myocardial damage not detected by CK-MB so it is the more commonly done test to diagnose MI. Levels elevate within 4 to 6 hours of damage. These levels peak in 10 to 24 hours and remain elevated for 10 to 14 days. Troponin T appears slightly earlier than troponin I and remains elevated longer after cardiac damage.

**MYOGLOBIN.** Myoglobin, a protein found in skeletal and cardiac muscle, is not site specific so it can only indicate that muscle damage has occurred. However, it rises before CK-MB or troponin so it can detect a MI earlier for prompt treatment. Myoglobin levels elevate within 1 hour of an acute MI. Peak levels are reached 4 to 12 hours after a MI, and levels return to normal within 18 hours after the onset of chest pain.

**Magnesium**
Magnesium, an electrolyte, is important to many functions in the body. Among these is control of the heartbeat, and regulating blood pressure. A normal magnesium level is 1.6 to 2.6 mg/dL. **Hypomagnesemia**, a low level of magnesium in the blood, can cause cardiac arrhythmias, hypertension, and tachycardia. Many things can contribute to low magnesium levels, including diuretic therapy, digitalis, some antibiotics, diabetes mellitus, and MI.

### Invasive Studies

**Angiography**
Arteriography and venography are the two types of angiography (Fig. 21.14). Arteriography examines arteries. Venography studies veins. Angiography uses dye injected into the vascular system to visualize the vessels on radiographs. This test is used to assess blood clot formation, peripheral vascular disease, and test vessels for potential grafting use.

The patient must be assessed for allergies, give informed consent, be NPO for about 4 hours before the test, and be informed that the dye produces a hot, burning feeling when injected. After the procedure the patient is assessed for several hours. Vital signs, allergic reaction signs, hemorrhage at the injection site, and pulses are monitored.

**Cardiac Catheterization**
Cardiac catheterization allows the heart’s anatomy and physiology to be studied or therapeutic procedures to be done. As an invasive diagnostic procedure, it measures pressures in the heart chambers, great blood vessels, and coronary arteries and provides information on cardiac output and oxygen saturation. Fluoroscopy, an x-ray procedure that produces real-time images of internal organs in motion on a video monitor, is used to guide the insertion of the catheter into the heart. Dye can be injected once the catheter is in place to visualize the heart chambers and vessels. This procedure is often done before heart surgery.

An informed consent must be obtained. The patient is assessed for allergies to contrast agents used in the procedure. IV hydration may be given before the procedure while the patient is NPO. Patients should be told that during the test they will be awake and a warm, flushing sensation may be felt when the dye is injected; the room has a lot of equipment; a movable table is used; the patient’s vital signs and ECG are monitored constantly; and the length of the procedure is 2 to 3 hours.

In right-sided catheterization, a catheter with or without a fiber-optic tip is inserted into the jugular vein (neck) or the femoral vein (leg) and advanced into the vena cava. It is then moved through the right chambers of the heart and into the pulmonary artery. The catheter can be wedged momentarily in the artery by inflating the balloon at the tip of the catheter. This position provides the pulmonary artery wedge pressure, which reflects pressures in the left side of the heart. Other pressures obtained with right-sided cardiac catheterization are right atrial pressure, which reflects central venous pressure, pulmonary artery systolic and diastolic pressures, cardiac output, and mixed venous oxygen saturation (SvO₂) if a fiber-optic catheter is used.

The left side of the heart can be directly assessed by inserting a catheter into the radial artery or the femoral artery. It is advanced against the flow of blood into the aorta, through the aortic valve, and into the left ventricle. Coronary angiography, which visualizes the coronary arteries with dye, can be done with this approach. The catheter is inserted into the opening of the coronary arteries, the dye is injected, and x-ray films are produced.
Chapter 21  Cardiovascular System Function, Assessment, and Therapeutic Measures

Coronary artery disease can be assessed with coronary angiography. After the procedure, the catheter is removed, and firm pressure must be applied to the insertion site for several minutes to prevent hemorrhage or hematoma formation. A pressure dressing or sandbag may be applied to the site when bleeding is stopped and is removed after several hours. Vital signs are assessed according to the HCP’s orders and the institution’s policies. During vital sign checks, the puncture site is assessed and peripheral pulses are verified. The patient is on bed rest without moving or flexing the leg for a few hours to allow healing of the puncture site, if the groin was used. For comfort, modified positioning and use of a pillow may be used without complications as ordered. Patients can eat and are instructed to drink fluids to help eliminate the dye from the body. If the patient is stable and no significant findings are found, the patient may be discharged.

Complications of cardiac catheterization can be allergic reaction, breaking of the catheter, hemorrhage, thrombus formation, emboli of air or blood, dysrhythmias, MI, cerebrovascular accident (stroke), and puncture of the heart chambers or lungs.

Hemodynamic Monitoring

Bedside monitoring can be done to monitor the pressures in the blood vessels or heart. A catheter attached to a transducer and monitor, called an arterial line, can be inserted into the radial or femoral artery to measure continuous arterial blood pressure.

Ongoing monitoring of cardiac pressures, cardiac output, and central venous pressure can be done with either a central catheter or a pulmonary artery catheter. Central venous pressure is measured directly with a central catheter inserted into the vena cava via the brachial, femoral, subclavian, or jugular vein. It is measured indirectly with the pulmonary artery catheter (Fig. 21.15). The right atrial pressure measurement obtained from the pulmonary artery catheter reflects the pressure in the vena cava. Central venous pressure measures preload (pressure stretching the ventricle of the heart from fluid returned to the heart) or fluid volume status; central venous pressure readings used in fluid or diuretic therapy have been primarily replaced by pulmonary artery catheter measurements.

Electrophysiological Study

To study the heart’s electrical system, one or more catheters with electrodes are inserted via the femoral vein into the right side of the heart. Two to three electrodes are usually inserted. The heart’s electrical impulses are then recorded and pacing can also be done. Dysrhythmias can be triggered to help the HCP diagnose why they are occurring. A consent is obtained, and the patient is NPO 6 to 8 hours before the test.

THERAPEUTIC MEASURES FOR THE CARDIOVASCULAR SYSTEM

Exercise

A prescribed walking program helps promote blood flow by contracting the skeletal muscles and may reduce symptoms of peripheral vascular disease. For patients recovering from cardiac surgery or a MI, activity is gradually increased. Exercise is very important for optimum cardiac functioning. A cardiac rehabilitation program is usually prescribed, and individualized exercise goals are determined. After discharge from the hospital, exercise three times a week for 20 to 30 minutes is encouraged.
Smoking Cessation

Smoking causes vasoconstriction that can last up to 1 hour after smoking one cigarette. For patients with cardiac or vascular disease, blood flow is reduced, which can exacerbate symptoms. Patients should be encouraged to stop smoking and be provided with support information such as cessation programs and support groups. For more information on smoking cessation, visit www.americanheart.org.

Diet

Teaching the patient to eat a healthy, balanced diet is important to help reduce the risk for coronary artery disease. Weight reduction, if needed, is encouraged, as well as increasing physical activity. Eating at least five servings of fruits and vegetables daily, increasing fish intake, and eating poultry without skin are parts of a healthy diet.

Oxygen

Supplemental oxygen is administered to patients with chest pain to help ensure that the heart receives sufficient oxygen to function. Oxygen may be delivered via a nasal cannula or facemask. The patient must be taught safety precautions necessary for home use of oxygen if it is ordered, such as avoiding open flames and not smoking when the oxygen is in use.

Medications

The primary cardiovascular drugs are cardiac glycosides, vasodilators, antihypertensives, antidysrhythmics, antianginals, anticoagulants, and thrombolytics. They are discussed in further detail where the disorders they are used to treat are discussed (see “Nutrition Notes—CYP Enzymes and Fruit Juices”).

### Nutrition Notes

**CYP Enzymes and Fruit Juices**

Cytochrome P450 (CYP450) is a superfamily of more than 50 enzymes found mainly in the liver but also in the gastrointestinal (GI) tract, lungs, placenta, and kidneys. The isoenzyme CYP3A4, found in the small intestine, plays a major role in regulating the oral bioavailability of many drugs, a function that may have evolved to protect the body from toxins. After uptake by the intestinal epithelial cells (enterocytes), many substances are metabolized by CYP3A4 or returned to the intestinal lumen by a transporter protein, P-glycoprotein (P-gp), thus providing repeated opportunities for CYP3A4 enzymes to metabolize the drug and thereby limiting the amount of the substance available for absorption.

People show wide variation in the amount of CYP3A4 in the liver and intestine due to genetic, physiologic, and environmental factors with resulting differences in the severity of interactions.

The effect of grapefruit juice on drugs was discovered accidentally when the juice was used to mask the taste of a medication being tested. Grapefruit juice appears to inhibit intestinal CYP3A4 so that the oral bioavailability of affected drugs is increased dramatically, in some cases enough to cause drug toxicity or treatment failure. Even when intake of grapefruit juice is stopped, the increased bioavailability of the affected drugs continues for 3 to 5 days until the intestine can synthesize more of the enzyme.

Applying this knowledge to clinical practice is complicated by the fact that even within a given class of drugs, not all are metabolized by CYP3A4. For instance, of calcium channel blockers given to manage hypertension and angina pectoris, grapefruit juice:

- Increases bioavailability of felodipine (Plendil), nifedipine (Adalat), nisoldipine (Sular), and nicardipine (Cardene)
- Shows little interaction with amlodipine (Norvasc)

Likewise, differing effects with grapefruit juice are seen with statin drugs, given to lower cholesterol and prevent ischemic heart disease:

- Simvastatin (Zocor) and lovastatin (Altova) have greatly increased blood levels when given with grapefruit juice.
- Atorvastatin (Lipitor) showed a lesser effect than the previous two drugs.
- Pravastatin (Pravachol) showed no effect.

Similarly, grapefruit juice increases the bioavailability of the benzodiazepines:

- Clobazam (Onfi), diazepam (Valium), and triazolam (Halcion)
- But not alprazolam (Xanax).

A similar mechanism but a different isoenzyme is proposed to explain an interaction between warfarin (Coumadin) and cranberry juice. Warfarin is mainly metabolized by the cytochrome P450 isoenzyme CYP2C9, and cranberry juice contains flavonoids known to inhibit P450 enzymes. Bleeding problems and hemorrhage have been attributed to this interaction.

### Antiembolism Devices

Antiembolism devices improve arterial blood flow and venous return to prevent the formation of blood clots. They are used for patients with peripheral vascular disease, on bedrest, or after surgery or trauma.

### Elastic Stockings

Antiembolism stockings apply compression to the leg to promote the movement of fluid and prevent stasis of fluid. These stockings may be knee or thigh length. They must be applied correctly so that a tourniquet effect is not produced by the stockings. For ease in application, the stocking is turned inside out to the heel, the foot portion is placed on the patient up to the heel, and then the remaining stocking is pulled up over the leg. The tops of the stockings should be 1 to 2 inches below the bottom of the kneecap. They should not roll down, or they will cause stasis rather than prevent it. Some patients
may require assistance in applying the stockings if they have impaired manual dexterity. Devices are available that aid in applying the stockings, such as the Sigvaris Doff N’ Donner.

**Intermittent Pneumatic Compression Devices**

An intermittent pneumatic compression device consists of plastic inflatable stockings that are filled intermittently with air by an attached motor (Fig. 21.17). This device simulates the contraction of the leg muscles, promoting fluid movement, which helps to prevent thrombosis development. The compartments in the stockings inflate to 35 to 55 mm Hg of pressure, beginning in the ankle compartment and progressing next to the calf compartment and finally the thigh compartment. Monitor the device for proper pressure inflation.

**Health Promotion and Lifestyle Changes**

To reduce risk factors or promote recovery from cardiovascular disease, lifestyle changes are often needed. Long-standing habits are difficult to change. Support groups can offer encouragement that is helpful in promoting a healthy lifestyle. Patients should be referred to community support groups as needed.

Patients recovering from cardiac disorders are often anxious about resuming sexual activity but are embarrassed to discuss it. This is an area that is often overlooked when caring for patients. Sexual counseling should be offered to patients and their partners. Patients often have misconceptions that are unfounded but interfere with resuming sexual activity. If patients have angina, nitroglycerin can be taken prophylactically before sexual activity. After a MI, sexual activity can be resumed in 1 to 2 months or when the patient can climb two flights of stairs without symptoms, as ordered by the HCP. Patients are given information to make an informed decision on when they are ready to resume this physical activity. Referral to a sexuality counselor for information on ways to cope with sexual issues in relation to their illness can be helpful to the patient.

**Cardiac Surgery**

As heart disease symptoms increase in severity and frequency or the disease process worsens, cardiac surgery may be used as treatment.

**Preparation for Surgery**

A nursing assessment is important to provide baseline data that can be used for postoperative comparison and early discharge planning. In addition to routine admission testing, patients with chronic obstructive pulmonary disease (COPD) may have pulmonary function tests and baseline arterial blood gases (ABGs) done (Box 21-3). Patients with carotid bruits have carotid studies to determine the amount of occlusion in the carotid artery. If the occlusion is significant, a carotid endarterectomy, which removes the plaque on the lining of the blocked or diseased carotid artery, is performed, usually several weeks before having cardiac surgery.

Medications that may increase bleeding or reduce fluid volume may be ordered by the HCP to be held before surgery. Drugs that increase bleeding include aspirin, often stopped 3 to 7 days preoperatively; warfarin (Coumadin), often stopped 4 to 5 days preoperatively; and heparin, usually stopped 4 hours preoperatively. During surgery, fluid volume and blood pressure may be decreased by blood loss or medications. Therefore, diuretics, which could further reduce fluid volume and blood pressure, are withheld up to 2 days before surgery. The patient usually takes nothing by mouth (NPO) 8 to 12 hours before surgery. For this reason, patients with diabetes have insulin and oral hypoglycemic agents reduced or withheld the morning of surgery with blood glucose monitoring. The anesthesiologist assesses the patient before surgery and orders preoperative medications.

Patients recover more quickly and have less postoperative stress with thorough preoperative teaching. Explanations of expected procedures and care including pain management, endotracheal tube, methods of communicating, ventilator, chest tubes, coughing and deep breathing exercises (IV lines, urinary catheter, incision care, and various equipment alarms) are provided to the patient and family. It should be emphasized that patients are not able to talk while the endotracheal tube is in place. Additionally, a preoperative family tour of the patient’s postoperative unit and the waiting area helps prepare them for the surgical experience. A referral to pastoral care, if desired, can be comforting to the patient and family.

**Box 21-3 Routine Admission Testing**

- Twelve-lead electrocardiogram (ECG)
- Chest x-ray
- Complete blood cell count (CBC)
- Coagulation studies
- Chemistry profile
- Blood cross-match
**Cardiopulmonary Bypass**

Cardiac surgeries may use a cardiopulmonary bypass pump in which blood is temporarily diverted away from the heart and lungs to the special pump (Fig. 21.18). This diversion allows for a bloodless and motionless surgical field while the function of the heart and lungs is maintained by the pump (Fig. 21.19).

Before going on the pump, the patient is anticoagulated with heparin until the partial thromboplastin time (PTT) is five to six times greater than normal. Immediately before the patient comes off the pump, the effects of the heparin are reversed with protamine sulfate (antidote for heparin). Heparin is absorbed and stored in organs and tissue and can be sporadically released hours after surgery. As a result, the patient may have excessive bleeding. The risk of an air embolism is minimized by priming the pump with lactated Ringer’s solution. The priming solution increases circulating volume, which then results in a shifting of fluid into the interstitial tissue and edema formation. These fluid shifts can continue up to 6 hours after surgery and can cause hypotension.

**General Procedure for Cardiac Surgery**

After the patient is placed on cardiopulmonary bypass, a cardioplegic solution is infused into the aortic root along with iced saline to cause cardiac standstill. When the surgery is completed, the patient’s blood is warmed in the cardiopulmonary bypass circuit and the patient is slowly weaned from bypass. The heart starts beating again after it is warmed and defibrillated. Temporary pacing wires are attached to the heart before the cardiopulmonary bypass pump is discontinued, so an external temporary pacemaker can be used if bradycardia develops. Once the heart is beating, bypass is stopped. Mediastinal chest tubes are placed to drain remaining blood and fluid from the chest. The **sternotomy** is closed with wires through the sternum and then sutures for the layers of tissue and skin. While still under anesthesia, the patient is transferred to a cardiac care unit. Cardiac universal beds may be used, in which patients stay in the same room during their entire hospitalization to receive care.

**Minimally Invasive Cardiac Surgery**

Minimally invasive direct visualization coronary artery bypass (MIDCAB) is a technique that is done without the use of cardiopulmonary bypass. Port-access coronary artery bypass combines peripheral cardiopulmonary bypass with minimally invasive heart access (see Chapter 24). Risk for complications associated with these surgeries are much lower than with the traditional procedure, and the recovery time is often weeks less.

Chapter 21  Cardiovascular System Function, Assessment, and Therapeutic Measures

CRITICAL THINKING

Mrs. Smith

1. An older patient commonly does not experience typical disorder symptoms. Chest pain is often not present in an MI because of reduced nerve sensitivity with aging. Dyspnea is the classic symptom of MI in the older patient.

2. Inspect both legs to determine edematous areas. Determine location and severity of edema by pressing finger for 5 seconds over the medial malleolus and moving up the leg along the tibia until no edema is found. Assess bilaterally. Measure leg circumference.

3. Document location of edema and whether edema is nonpitting or pitting for both legs. Documentation should state “Bilateral pitting ankle edema” with leg circumference measurement number.

SUGGESTED ANSWERS TO

4. Additional symptoms should be documented as follows: dyspnea at rest that increases with exertion, heart tones clear and distant, nailbeds pale, pain free, poor appetite for 2 weeks, 6-pound weight gain in 1 week, three-pillow orthopnea, bilateral jugular venous distention.

5. Unit analysis method:

\[
\begin{align*}
162 \text{ pounds} & \quad 1 \text{ kilogram} \\
2.2 \text{ pounds} & \quad = 73.6 \text{ kilograms}
\end{align*}
\]

6. HCP, nurses, pharmacist, respiratory therapist, dietician, social worker or case manager

REVIEW QUESTIONS

1. The nurse is contributing to the plan of care for a patient with heart disease. Which of the following is a modifiable cardiovascular risk factor identified during patient data collection that should be included in the teaching plan?
   1. 56 years old
   2. Male
   3. Asian
   4. Tobacco use

2. The nurse is checking capillary refill on a patient. If it takes longer than 3 seconds for the color to return when assessing capillary refill, the nurse would recognize that which of the following may be indicated?
   1. Decreased arterial flow to the extremity
   2. Increased arterial flow to the extremity
   3. Decreased venous flow from the extremity
   4. Increased venous flow from the extremity

3. The nurse is to obtain orthostatic blood pressure measurements. Which of the following is an important safety intervention that should be used during this procedure?
   1. Reality orientation
   2. Gait or walking belt
   3. Liquids at bedside
   4. Standing patient quickly

4. The nurse is caring for a patient on bed rest who is on diuretic therapy. In which area should the nurse check for the presence of edema?
   1. Arms
   2. Ankles
   3. Sternum
   4. Sacrum

5. The nurse is providing teaching for a patient undergoing a coronary angiography. Which of the following should be included in the teaching plan for a coronary angiography with femoral catheter insertion site? Select all that apply.
   1. Dye injection causes hot, flushing sensation.
   2. General anesthesia is administered.
   3. Claustrophobia may be experienced.
   4. Ambulation is not possible immediately after procedure.
   5. Allergies are assessed before testing.
   6. Firm pressure must be applied to the insertion site.

6. The nurse is reinforcing teaching about a high-fiber diet for a cardiac patient. The patient asks what the purpose of the diet is. Which of the following replies by the nurse would be appropriate?
   1. “To increase absorption of nutrients in your diet.”
   2. “It will reduce your heart’s workload.”
   3. “To prevent edema from developing.”
   4. “To reduce your appetite.”

7. A patient is scheduled for vascular surgery. The patient is taking digoxin (Lanoxin), furosemide (Lasix), potassium, warfarin (Coumadin), and famotidine (Pepcid). Which medication would the nurse question the possible need to stop several days before surgery?
   1. Digoxin (Lanoxin)
   2. Furosemide (Lasix)
   3. Warfarin (Coumadin)
   4. Famotidine (Pepcid)

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Explain the pathophysiology of hypertension.
2. Identify causes and risk factors for hypertension.
3. List signs and symptoms of hypertension.
4. Describe therapeutic measures for hypertension.
5. Define classifications and treatment recommendations for hypertension in adults.
6. Define hypertensive emergency.
7. List common complications of hypertension.

KEY TERMS

- cardiac output (KAR-dee-yak OWT-put)
- diastolic blood pressure (dy-uh-STAH-lik BLUHD PREH-shure)
- essential hypertension (ee-SEN-shul HY-per-TEN-shun)

- systolic blood pressure (siss-TALL-ik BLUHD PREH-shure)
- viscosity (vis-KAW-sih-tee)
During 2011–2012, 29.9% of U.S. adults aged 18 or older had hypertension. The prevalence of those with hypertension increases with age, from 7.3% in those aged 18 to 39 to 65% in those ages 60 or older (Nwankwo, Yoon, Burt, & Gu, 2013). The highest occurrence was in non-Hispanic blacks at 42.1%, then non-Hispanic whites at 28%, followed by Hispanics at 26%. The prevalence of hypertension remains high despite effective treatments.

The 2014 Evidence-Based Guideline for the Management of High BP in Adults by the Eighth Joint National Committee (JNC 8; James et al, 2014) takes a different approach than the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High BP (JNC 7; National Heart, Lung, and Blood Institute, 2004). JNC 8 does not define hypertension, as JNC 7 did, but rather defines pharmacologic treatment thresholds, recommends drug therapy, and supports the 2013 American Heart Association/American College of Cardiology (AHA/ACC) lifestyle modifications guidelines (James et al, 2014).

The lifestyle interventions to reduce cardiovascular risk are identified in the 2013 AHA/ACC Guideline on Lifestyle Management to Reduce Cardiovascular Risk. In general, the guidelines recommend restricting sugary foods and beverages, trans and saturated fats, and sodium; following a Dietary Approaches to Stop Hypertension (DASH)-type (see “Nutrition Notes”) or Mediterranean diet with fruits, vegetables, whole grains, nuts, low-fat dairy, poultry, fish and non-tropical vegetable oils; and participating in 40 minutes of moderate to vigorous aerobic activity three to four times weekly (Eckel et al, 2013).

Follow-up studies involving overweight or obese persons with above-normal BP found the DASH diet alone reduced BP by 11.2/7.5 mm Hg but the addition of exercise and weight loss to the DASH diet resulted in reductions of 16.1/9.9 mm Hg. Even the control group consuming their usual diet recorded 3.4/3.8 mm Hg reductions in the 4-month program (Blumenthal et al, 2010). In this same group, greater adherence to the DASH diet was associated with larger BP reductions independent of weight loss. African Americans were less likely to adhere to the DASH dietary eating plan compared with whites, suggesting that culturally sensitive dietary strategies might be needed to improve adherence to the DASH diet (Epstein et al, 2012).

The JNC 7 redefined normal and abnormal BP for adults aged 18 and older (Table 22.1 www.nhlbi.nih.gov/guidelines/hypertension/express.pdf). Because they were not addressed nor eliminated by JNC 8, they remain included here.

### BP MEASUREMENT

It is essential to take BP readings correctly for accurate readings. A normal BP reading is one in which systolic pressure is below 120 mm Hg and diastolic pressure is below 80 mm Hg with the patient in a seated position and the arm supported at heart level (see Chapter 21). Prehypertension is a systolic BP of 120 to 139 mm Hg or a diastolic BP of 80 to 89 mm Hg. Hypertension, also known as high BP, is a condition in which the average of at least two or more readings on different dates is above prehypertension levels. For more information on hypertension, visit www.americanheart.org.

---

**Nutrition Notes**

### Reducing BP With Diet

The original DASH diet reduced blood pressure (BP) significantly in normotensive people and produced even greater reductions in hypertensive people in an 8-week feeding trial that was designed to maintain the subjects’ starting weight. Rather than emphasizing food restriction, the DASH diet increases the intake of certain commonly available, not specialty, foods. On a 2,000-calorie diet, a person following the DASH diet would consume the following:

<table>

**WORD BUILDING**

- **systolic:** systole—concentration
- **diastolic:** diastole—expansion
- **hypertension:** hyper—excessive + tension—tension
Normally the heart pumps blood through the body to meet the cells’ needs for oxygen and nutrients. As it pumps, the heart forces blood through the blood vessels. The pressure exerted by blood on the walls of the blood vessels is measured as BP. BP is determined by cardiac output (CO), peripheral vascular resistance (PVR; the ability of the vessels to stretch), the viscosity (thickness) of the blood, and the amount of circulating blood volume. Decreased stretching ability of blood vessels, increased blood viscosity, and/or increased fluid volume may cause an increase in BP.

**BE SAFE!**

Research studies show that stethoscopes used by all types of health care providers (HCPs), such as nurses, physicians, paramedics, and emergency medical technicians, are contaminated with bacteria. With infection rates on the rise, reduce the transmission of organisms to help keep your patients safe. Clean your stethoscope between every patient! (See “Evidence-Based Practice.”)

**EVIDENCE-BASED PRACTICE**

**Clinical Question**

Are stethoscopes contaminated, and what is the best way to decontaminate them?

**Evidence**

An observational study of 100 nurses and their stethoscopes found high stethoscope contamination rates in the emergency department, with a low prevalence of *Staphylococcus aureus* or methicillin-resistant *S. aureus* (MRSA) and that only 8% of nurses cleaned their stethoscopes (Tang, Worster, Srigley, & Main, 2011). In a study comparing an ethanol-based cleanser (EBC) with isopropyl alcohol pads in reducing bacterial contamination of stethoscope diaphragms, 99 stethoscopes were cultured, and all were positive for bacterial growth (Lecat, Cropp, McCord, & Haller, 2009). The use of either EBC or isopropyl alcohol reduced the bacteria count significantly.

**Implications for Nursing Practice**

Stethoscopes become contaminated with use. To protect patients from potential organism transmission and reduce infection, stethoscopes must be cleaned between every patient by all HCPs. Stethoscopes should be cleaned as often as hands are washed using either EBC or isopropyl alcohol pads.

**REFERENCES**

**PATHOPHYSIOLOGY OF HYPERTENSION**

Normally the heart pumps blood through the body to meet the cells’ needs for oxygen and nutrients. As it pumps, the heart forces blood through the blood vessels. The pressure exerted by blood on the walls of the blood vessels is measured as BP. BP is determined by cardiac output (CO), peripheral vascular resistance (PVR; the ability of the vessels to stretch), the viscosity (thickness) of the blood, and the amount of circulating blood volume. Decreased stretching ability of blood vessels, increased blood viscosity, and/or increased fluid volume may cause an increase in BP.

**WORD BUILDING**

viscosity: viscous—sticky
Several processes influence BP. These include nervous system regulation, arterial baroreceptors and chemoreceptors, the renin-angiotensin-aldosterone mechanism, and the balance of body fluids. One way BP is influenced is through adjustment of the CO, which is the amount of blood that the heart pumps each minute. The heart rate rises to increase CO in response to physical or emotional activities that increase the need for oxygen in the organs and tissues. PVR also influences BP; it is the opposition that blood encounters as it flows through vessels. Anything causing blood vessels to become narrower increases PVR. Any time PVR is increased, more pressure is needed to push the blood through the vessels, so BP increases as a result. If PVR is decreased, less pressure is needed. Increased arteriolar PVR is the main mechanism that elevates BP in hypertension.

Factors that impair normal regulation of BP may lead to hypertension. Many of these factors are not well understood. Sympathetic nervous system overstimulation, which causes vasoconstriction, can contribute to hypertension. Alterations in baroreceptors and chemoreceptors may also influence the development of hypertension. For example, baroreceptors may become less sensitive from prolonged increases in vessel pressure, and subsequently fail to stimulate vasodilation through vessel stretching. Additionally, increases in hormones that cause sodium retention, such as aldosterone, lead to increased fluid retention. Changes in kidney function that alter the excretion of fluid also result in an increase in overall body fluid that may contribute to hypertension.

Types of Hypertension
Primary Hypertension
Primary, or essential, hypertension is chronic elevation of BP from an unknown cause.

Secondary Hypertension
Secondary hypertension has a known cause. In other words, it is a sign of another problem, such as a kidney abnormality, a tumor of the adrenal gland, or a congenital defect of the aorta. When the cause of secondary hypertension is treated before permanent structural changes occur, BP usually returns to normal.

Isolated Systolic Hypertension (ISH)
ISH is a systolic pressure of 140 mm Hg or greater and a diastolic pressure of 90 mm Hg or less. This type of hypertension occurs mainly in the older adult, although it can occur at any age (“Gerontological Issues”). People with a systolic pressure higher than 140 mm Hg and a diastolic pressure less than 90 mm Hg found on two separate readings should be further evaluated. Treatment of ISH is recommended to decrease cardiovascular disease, especially heart failure episodes and risk of stroke. Lifestyle modifications are usually tried first if the systolic elevation is not too severe. If lifestyle modifications fail to reduce the systolic pressure, antihypertensive medication is added.

Alcohol consumption in the older adult can aggravate age-related hypertension. Guided relaxation has been shown effective in reducing high BP in older adults.

It is now known that after age 55, diastolic pressure falls while systolic pressure continues to rise with age. This means that it is important to control systolic BP, not just diastolic pressure, in older adults to prevent heart disease and stroke. In fact, lowering diastolic BP too much may be unhealthy.

Have you known someone with high BP? Did that person have signs and symptoms of hypertension? If not, it is because hypertension often causes no signs or symptoms other than elevated BP readings. As a result, hypertension is referred to as the “silent killer.” Patients with hypertension are often first diagnosed when seeking health care for reasons unrelated to hypertension. In a small number of cases, a patient with hypertension may report a headache, bloody nose, severe anxiety, or shortness of breath, although it is usually impossible for a patient to correlate the absence or presence of symptoms with the degree of BP elevation (Table 22.2).

Diagnosis of hypertension considers a patient’s risk factors for hypertension, a previous diagnosis of hypertension, presence of signs and symptoms, history of kidney or heart disease, and current use of medications. When the average seated BP is above prehypertensive levels of 120 to 139 systolic or 80 to 89 diastolic on two or more occasions, then hypertension is diagnosed (see Table 22.1).

The JNC 7 recommends that patients undergo various routine tests to identify damage to organs or blood vessels before beginning therapy for high BP. Tests recommended by JNC 7 include electrocardiogram (ECG), blood glucose level, hematocrit, serum potassium and calcium levels, lipoprotein profile, high-density and low-density lipoprotein cholesterol (HDL-C and LDL-C, respectively), and triglyceride level. These tests help determine if target-organ damage has been caused by elevated BP. An example of this is testing for kidney damage with a urinalysis or serum creatinine level.

A combination of genetic (nonmodifiable) and environmental (modifiable) risk factors is thought to be responsible for the development of hypertension, although the cause remains unknown. Nonmodifiable risk factors—those that cannot be changed—include a family history of hypertension, age,
ethnicity, and diabetes mellitus. Modifiable risk factors—those that can be changed—include blood glucose level, activity level, smoking, salt and alcohol intake, and insufficient sleep (less than 5 hours per night). Managing these risk factors can help to decrease BP.

### Nonmodifiable Risk Factors

#### Family History of Hypertension

Hypertension is more common among people with a family history of hypertension. Indeed, people with a family history have almost twice the risk of developing hypertension as those with no family history. People with a family history of hypertension should be encouraged to have their BP checked regularly.

### Age

People age differently because of their genetic and environmental risk factors and lifestyle habits. Thus, the results of the aging process may be reflected in wide variations of BP among older adults. As a person ages, plaque builds up in the arteries, and blood vessels become stiffer and less elastic, causing the heart to work harder to force blood through the vessels. These vessel changes increase the amount of work required by the heart to maintain blood flow into the circulation and, consequently, BP increases.

### Race and Ethnicity

“Cultural Considerations” discusses hypertension among various ethnic groups.

---

### Cultural Considerations

**African Americans**

Hypertension continues to be the most serious health problem affecting African Americans in the United States. This population suffers higher mortality and morbidity rates related to hypertension and at an earlier age than all other ethnic groups. African Americans from lower socioeconomic backgrounds have higher BP than African Americans from higher socioeconomic backgrounds. Additionally, African Americans are three to four times more likely to develop kidney failure related to hypertension than European Americans. Addressing obesity, high sodium intake, low potassium intake, and lack of physical activity is especially important for cardiovascular health in African Americans.

Hypertension among African Americans is usually caused by increased renin activity, resulting in greater sodium and fluid retention. Thus, African Americans respond better to diuretics such as furosemide (Lasix) and hydrochlorothiazide (HydroDIURIL) than to beta blockers such as propranolol (Inderal). Hypertension among European Americans is more often caused by chemical imbalances; thus, they respond better to beta blockers.

**Chinese Americans**

Chinese people are more sensitive than Caucasians to the effects of propranolol on heart rate and BP, requiring only half the blood level of European Americans to achieve a therapeutic effect. Propranolol is eliminated from the bodies of many Chinese people at double the rate of European Americans. They are more likely to suffer fatigue as a side effect. Thus, the nurse must carefully monitor the Chinese patient for therapeutic and side effects.

---

### Table 22.2 Hypertension Summary

| Signs and Symptoms | Often none  
|--------------------| Increased BP  
|                    | Headache, bloody nose, severe anxiety, or shortness of breath  
| Diagnosis          | Prehypertension is greater than systolic of 120 mm Hg and diastolic of 80 mm Hg.  
|                    | Hypertension is an average BP, using two or more readings on different dates, greater than a systolic of 139 mm Hg and diastolic of 89 mm Hg.  
| Therapeutic Measures | Lifestyle modification  
|                    | Medications  
| Complications      | Heart failure, myocardial infarction, stroke, renal failure  
| Priority Nursing Diagnoses | Deficient Knowledge  
|                    | Ineffective Self Health Management  

---

Continued
Diabetes Mellitus

Many adults who have diabetes mellitus also have hypertension. The risk of developing hypertension with a family history of diabetes and obesity is greater than when there is no family history. Lifestyle modifications and adherence to therapy are crucial to prevent the heart attacks, strokes, blindness, and kidney failure associated with high blood glucose and BP levels.

Modifiable Risk Factors: Lifestyle

JNC 8 supports patients with hypertension making lifestyle modifications. These modifications include adoption of the DASH or Mediterranean diet, reduction of dietary sodium, and increased physical activity (see “Nutrition Notes”; Eckel et al, 2013). The HCP and dietitian should be consulted to help the patient develop a healthy diet plan. Lifestyle modifications are used along with antihypertensive drugs to control hypertension.

Cultural Considerations—cont’d

Japanese Americans

Hypertension among Japanese Americans is primarily related to the high sodium content of the Japanese diet, stress, and a high rate of cigarette smoking.

Korean Americans and Filipino Americans

High rates of hypertension among Koreans and Filipinos are due to the stress of immigration, salt preservatives in their foods, and the use of condiments high in sodium.

Critical Thinking

Ms. Miller

Ms. Miller, age 54, visits a health clinic because she has a headache every morning. The nurse collects data on Ms. Miller and finds that she is an office manager, smokes a pack of cigarettes a day, eats fast food for lunch at her desk, has two adult children, is recently divorced, and has two to three alcoholic drinks every evening. Ms. Miller has been in good health and takes two aspirin tablets for her headaches daily.

1. What are Ms. Miller’s risk factors for hypertension?
2. What is the most significant patient information identified? Why?
3. Why is hypertension referred to as the “silent killer”?
4. Why should Ms. Miller be told of the need for lifelong therapy if she is diagnosed with hypertension?

Suggested answers are at the end of the chapter.

Gerontological Issues

Managing Antihypertensive Therapy

- For safety, teach older adults who take antihypertensive drugs to rise slowly to prevent the effects of orthostatic hypotension. Dizziness may increase the risk of falling.
- Deficiencies in fluid volume can be a common problem for older adults as well, and diuretics can contribute to them. Careful monitoring of fluid balance is important to prevent dehydration.
- Older adults may be more sensitive to medications, so monitor them carefully for adverse effects. Older patients may need lower dosages.

Therapeutic Measures for Hypertension

JNC 8 recommends therapy to achieve a BP less than 150/90 mm Hg for those 60 and older; for those aged 30 to 59, the goal is a diastolic BP less than 90 mm Hg; and a goal BP less than 140/90 mm Hg for other adults. Treatment may begin with lifestyle modifications and then consideration of drug therapy. For initial drug therapy, a thiazide diuretic, angiotensin-converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), or calcium channel blocker (CCB) is recommended. African Americans should receive a CCB or thiazide diuretic (if chronic kidney disease with proteinuria ACE inhibitor or ARB), and anyone with chronic kidney disease an ACE inhibitor or ARB. For those with chronic kidney disease or diabetes, the goal BP is less than 140/90. If the response does not achieve the BP goal, dosage may be increased or a second drug from a different class may be added. See Table 22.3 for examples of medications used to treat hypertension. Safe administration of medications is important, especially for older patients (“Gerontological Issues”).

</tbody>
</table>
Aldosterone Receptor Antagonist
Blocks binding of aldosterone at receptor site to reduce sodium reabsorption and then BP.

Calcium Channel Blockers
Prevent movement of extracellular calcium into the cell which vasodilates.

Direct Vasodilators
Relax smooth muscles of blood vessels, causing vasodilation and decreased BP.

Combination Agents
See individual agent for action.

</table>

**Note.** GI, gastrointestinal; HF = heart failure; I&O = input and output; PO = oral; IV = intravenous.

**BE SAFE!**
Clonidine, an alpha-adrenergic agonist, and clonazepam, a benzodiazepine, have lookalike and sound-alike drug names. Be aware of drug names that look alike and sound alike to prevent errors involving these drugs.

Antihypertensive medications can have unpleasant side effects. Patients should be told what these side effects are and to report them if they occur, so that medications can be altered if possible. Erectile dysfunction can be one of the side effects of these medications. Men may be reluctant to discuss this side effect and instead choose to stop the medication. The nurse should be proactive and inform men about this side effect so they will understand that, if it occurs and is reported, the HCP can make medication changes.

The treatment plan of lifestyle modifications and medications is effective only when patients are motivated to accept the diagnosis of hypertension and include lifelong treatment in their daily routine. Empathy and trust can increase patient motivation. Patients should be instructed that antihypertensive therapy usually must be continued for the rest of their lives. Patients should be reminded that although they may be feeling better with the modifications and medications, the hypertension is still present even if it is well controlled. Patients should be told not to stop taking their medications unless instructed to do so by their HCP.

**COMPLICATIONS OF HYPERTENSION**

Common complications of hypertension include coronary artery disease, atherosclerosis, myocardial infarction (MI), heart failure (HF), stroke, and kidney or eye damage. The severity and duration of the increase in BP determine the extent of the vascular changes causing organ damage. High BP levels may also increase the size of the left ventricle, referred to as hypertrophy. Over time elevated BP damages the small vessels of the heart, brain, kidneys, and retina. The results are a progressive functional impairment of these organs, known as target-organ disease.
SPECIAL CONSIDERATIONS

BP should be well controlled before the patient has an invasive procedure. Hypertensive patients are at greater risk for strokes, MI, HF, kidney failure, and pulmonary edema. These patients should be instructed to continue their BP medications until the time of the procedure, unless otherwise directed by their HCP. Antihypertensive medications should be resumed as soon as possible after the procedure, as directed by the HCP.

CRITICAL THINKING

Mrs. Bell

Mrs. Bell, 80 years old, is seen in her physician’s office. She lives a sedentary lifestyle alone in her own home with a bathroom down the hall from the bedroom. Mrs. Bell’s son lives in the same city and visits her often. She has wood floors with throw rugs in the hall and a tile floor in the bathroom. She wears glasses and has a cataract. She has an unsteady gait and nocturia. She is 40 pounds overweight and has a 10-year history of hypertension for which she is taking chlorothiazide (Diuril) and propranolol (Inderal) when she remembers them.

1. What are Mrs. Bell’s modifiable and nonmodifiable risk factors for hypertension?
2. Why is Mrs. Bell taking chlorothiazide and propranolol to treat her hypertension?

3. What teaching methods could be used to help ensure that Mrs. Bell will understand and follow her treatment plan?
4. Why should patient safety needs be addressed in the nursing care plan?
5. What patient-centered safety interventions should the patient and family be taught?
6. Inderal 20 mg by mouth (PO) is ordered now because Mrs. Bell forgot to take her medication. The nurse has on hand Inderal 10-mg tablets. How many tablets should the nurse give?

Suggested answers are at the end of the chapter.

LEARNING TIP

Walking for 30 minutes is an effective way to lower BP, as is listening to 30 minutes of classical, Celtic, or raga music with slow abdominal breathing daily. Transcendental meditation also helps control high BP.

Here are additional, important lifestyle modifications arranged in an easy-to-remember mnemonic:

L—Limit salt, caffeine, and alcohol.
I—Include daily potassium and calcium.
F—Fight fat and cholesterol.
E—Exercise regularly (walking).
S—Stay on your BP regimen.
T—Try to quit smoking.
Y—Your medications are to be taken daily.
L—Lose weight.
E—End-stage complications will be avoided.

HYPERTENSIVE EMERGENCY

How would you know if a patient’s BP was in the dangerous range? Hypertensive emergency is a severe type of hypertension characterized by elevations in systolic BP greater than 180 mm Hg and diastolic BP greater than 120 mm Hg that are complicated by a risk for or progression of target-organ dysfunction (examples include MI, HF, and dissecting aortic aneurysm). Patients who are untreated, fail to adhere to antihypertensive therapy, or stop their medications abruptly are at risk for hypertensive emergency.

These patients require immediate reduction of BP to prevent or limit damage to target organs. Patients with hypertensive crises should be admitted to the critical care unit. In some cases, the BP may need to be reduced by 25% within 1 hour to prevent organ damage. If the patient is stable, BP is then decreased to 160/100 to 110 mm Hg in the next 2 to 6 hours. Gradual reduction of BP is desired to prevent decreased blood flow to the kidneys, heart, and/or brain. An intravenous (IV) medication such as nitroprusside (Nipride) may be given to quickly reduce BP during the crisis.

HYPERTENSIVE URGENCY

The JNC7 considers hypertensive urgency to occur in situations when BP is as elevated as in a hypertensive emergency but without progression of target-organ dysfunction. A patient with hypertensive urgency may have severe headaches, nosebleeds, shortness of breath, and severe anxiety. Patients with hypertensive urgency usually can be treated with combination oral medication and scheduled for a follow-up visit within several days.

NURSING PROCESS FOR THE PATIENT WITH HYPERTENSION

Data Collection

Data collection for a patient with hypertension includes the patient’s health history, BP measurements, medications, and
physical assessment (Fig. 22.1). Determining what hypertensive patients and their families know about hypertension and associated risk factors is essential for planning patient and family education and subsequent lifelong lifestyle modification needs.

**Nursing Diagnoses, Planning, Interventions, and Evaluation**

Possible nursing diagnoses, planning, interventions, and evaluation must be agreed on by the patient and the health care team. See the *Nursing Care Plan for the Patient With Hypertension*.

**NURSING CARE PLAN for the Patient With Hypertension**

**Nursing Diagnosis:** Deficient Knowledge related to disease process and treatment regimen

**Expected Outcome:** The patient will verbalize knowledge of disease process and treatment regimen.

**Evaluation of Outcome:** Is patient able to discuss and explain hypertension disease process, including its risk factors, complications, and treatment regimen?

**Intervention** Identify patient’s readiness and ability to learn. **Rationale** Patient must accept the hypertension diagnosis and be able to receive and understand information given. Determine patient’s preferred method of learning.

**Evaluation** Does patient verbalize acceptance of hypertension diagnosis? Does patient demonstrate ability to read, write, and retain information?

**Intervention** Provide patient with information concerning disease process including risk factors, complications, and treatment regimen. **Rationale** Patient will be more willing to participate in treatment regimen when able to understand need for changes in behavior. **Evaluation** Is patient able to participate in discussion concerning hypertension disease process including risk factors, complications, and treatment regimen?

**Nursing Diagnosis:** Ineffective Self Health Management related to complexity of therapy, cost of medications, lack of symptoms, side effects of medications, need to alter long-term lifestyle habits, normal BP controlled by therapy

**Expected Outcome:** The patient will verbalize ability and willingness to adhere to treatment.

**Evaluation of Outcome:** Is patient able to state how lifestyle will include therapy? Does patient identify and problem solve barriers for therapy?

**Intervention** Identify patient’s modifiable risk factors and lifestyle modification needs. **Rationale** Identifying risk factors is the first step in planning therapy. Patient must understand the relationship of these risk factors with hypertension and complication development. **Evaluation** Can patient state rationale for modifying risk factors to prevent development of complications?

Continued
NURSING CARE PLAN for the Patient With Hypertension—cont’d

**Intervention** Identify factors that are barriers to patient adhering to therapy. **Rationale** Factors such as finances, transportation, aging changes, patient motivation, habits, and reading and educational level can be barriers for therapy. **Evaluation** Are barriers present for patient?

**Intervention** Develop plan to overcome barriers. Make referrals as needed. **Rationale** Identified barriers can be overcome with planning and intervention, such as referral to support groups or for financial assistance or prescription delivery service, and instructions provided at level of patient’s learning ability. **Evaluation** Have barriers been eliminated? Is patient willing to use referrals?

**Intervention** Assess ability to take medications daily: financially, obtaining refills, understanding directions. **Rationale** Older adult patients may be on a fixed income, lack transportation, or lack ability to take several medications several times a day. Simplifying this process, to one medication if possible, can increase adherence to medication treatment. **Evaluation** Is patient able to obtain medications? Can patient self-administer medications accurately on daily basis?

**Intervention** Teach patient to change positions slowly to prevent falls. **Rationale** Antihypertensive medications can cause hypotension, resulting in dizziness and weakness and possibly leading to falls. **Evaluation** Does patient understand how to change positions slowly? Does patient experience dizziness or weakness?

**Home Health Hints**

- Discuss medication usage with the patient and count the number of remaining pills in the patient’s pill bottles, if needed, to assess compliance. Remind the patient to get refills and keep medical appointments by writing them on a calendar.

- Monitor carefully for symptoms of congestive HF if the patient takes a beta blocker. This is a side effect that needs to be caught early and reported to the HCP.

- Instruct patients to take medication as prescribed even if they are feeling well or if side effects, which they should report, are present. Medication compliance can be a challenge for the older adult patient with hypertension. If medicines are too expensive for the patient, check with the HCP and pharmacist for less expensive alternatives.

- Encourage the patient to obtain a home BP monitoring device. Instruct the patient or caregiver on proper use and logging the date, time, and reading obtained. The home health nurse should review the log on each visit.

- Teach the patient or caregiver to take the patient’s pulse and to call the nurse if it is below 60 beats per minute or the parameters defined by the HCP. Many antihypertensive medicines can cause bradycardia.

- Instruct patients to weigh themselves every morning after voiding, to wear the same amount of clothing each time, and to keep a log for the nurse to review.

- Advise patients who are leaving home for the weekend or holidays to refill medicines ahead of time to make sure they do not run out. The HCP can write a prescription for the patient to have for emergency refills.

- Discuss with the registered nurse if the DASH eating plan would be appropriate for the patient (see www.nhlbi.nih.gov/health/public/heart/hbp/dash/new_dash.pdf).

- Instruct patients and caregivers to avoid frozen dinners and deli meats because many are high in sodium.

- Teach patient to consult HCP about use of salt substitutes, which often contain potassium, because medication and electrolyte interactions can occur.

- Teach patients how to read food labels for fat and salt content. If patients are on a 2- to 3-g sodium diet, instruct them about eating breads or cereals that contain 200 mg or less of sodium per serving.
or canned vegetables that contain 150 mg of sodium per serving. Fresh vegetables are better, but cost and storage must be considered. Providing written suggestions for the caregiver who does the grocery shopping increases adherence to diet therapy.

- Provide the following suggestions to help a patient decrease or stop smoking: use cinnamon mouthwash on arising; put away all ashtrays but one, and keep it in a place not normally used for smoking; find ways to keep hands busy at times when usually holding a cigarette, such as when drinking coffee or alcohol.
- Encourage patients to put “No Smoking” signs on their door to avoid passive smoking.
- Promote home exercise if cleared by HCP. Weights for exercising can be improvised using canned goods and bags of sugar. The amount of weight being used is easily identified for documentation by the labeling on the food item.

CRITICAL THINKING

■ Ms. Miller
1. Risk factors include gender; age; smoking; a diet high in fat, salt, and calories; consumption of two to three alcoholic drinks per evening; and possibly her morning headaches.
2. Morning headaches. Ms. Miller may be experiencing an episode of hypertensive urgency and should be evaluated immediately by an HCP.
3. “Silent killer” refers to the fact that there are often no signs or symptoms associated with hypertension.
4. Lifelong therapy is required because there is no cure for hypertension, and complications need to be prevented.

■ Mrs. Bell
1. Nonmodifiable risk factors include age, gender, and history of hypertension. Modifiable risk factors include weight and adherence to antihypertensive therapy.
2. Thiazide diuretics are first-line drugs. Diuretics remove excess salt and water to decrease blood volume and lower BP. Beta blockers stop the beta receptors from receiving the message from the brain for the heart to work harder. Therefore, the heart rate and BP decrease.
3. Identify patient’s reading level and primary language. Provide patient with written instructions in large letters about medications. Include family members and enlist their support in reinforcing the importance of adhering to the treatment plan.
4. Patient is 80 years old, makes frequent trips to the bathroom related to diuretics, has vision problems, and a side effect of propranolol is weakness and fatigue.
5. Make arrangements for a bedside commode to reduce the distance and urgency to get to the bathroom. Encourage the patient and family to place nightlights in the bedroom, hall, and bathroom. Explain that throw rugs increase the risk of falling and that wood or tile floors can be slippery when wet and hard if a fall occurs. Encourage removal of throw rugs, and suggest carpeting these areas if possible. Suggest the use of safety bars in the hall and bathroom for support or other walking aids as needed. If incontinence is a concern, suggest wearing an adult brief to prevent a wet, slippery floor. Suggest discussing with the physician an exercise program to increase strength, such as lifting small, lightweight objects (e.g., soup can), squeezing a rubber ball, or riding an exercise bike if able. These exercises can be done while sitting so they are not a fall-risk activity.
6. Unit analysis method:

<table>
<thead>
<tr>
<th>20 mg</th>
<th>1 tablet</th>

REVIEW QUESTIONS

1. The nurse provides a teaching session for a newly diagnosed patient with hypertension. Which of the following statements if made by the patient would indicate the need for further teaching about the cause of primary hypertension? Select all that apply.
   1. It is caused by a tumor of the adrenal gland.
   2. There are no tests that can identify the cause.
   3. An arteriogram can show why hypertension is occurring.
   4. The cause is unknown.
   5. The cause can be identified with magnetic resonance imaging (MRI).

2. Which of the following would the nurse reinforce after a teaching session as the most important lifestyle modification for the patient who is age 59, 5'11”, weighs 280 pounds, and is hypertensive?
   1. Reduce weight.
   2. Restrict salt intake.
   3. Increase potassium intake.
   4. Decrease alcohol intake.

3. The nurse is reinforcing teaching on hypertension for a patient. Which of the following statements if made by the patient after a teaching session would indicate understanding of what is often the only sign of hypertension?
   1. Sacral edema
   2. Elevated BP
   3. Tachycardia
   4. Jugular venous distention

4. The nurse is participating in a teaching session on diet for a patient with hypertension. Which of the following statements if made by the patient would indicate understanding of the teaching? Select all that apply.
   1. “Canned fruit and vegetables are best to eat.”
   2. “Add salt to food during cooking.”
   3. “Increase foods high in saturated fat.”
   4. “Choose fresh or frozen fruits and vegetables.”
   5. “Read food labels.”
   6. “Watch for potassium in salt substitutes.”

5. The nurse is obtaining BP readings for patients during a clinic visit. For which of the following BP readings should a 1-year follow-up visit be recommended in the patient’s teaching plan?
   1. 108/66 mm Hg
   2. 116/76 mm Hg
   3. 138/84 mm Hg
   4. 142/90 mm Hg

6. During a health screening, a patient’s BP is confirmed by two nurses to be 210/120 mm Hg. Which of the following actions should the nurse recommend to the patient?
   1. Take off work for the rest of the day and rest.
   2. Sit quietly while we call 911 to request an ambulance.
   3. The patient should take two doses of BP medication right now.
   4. The patient may return to work and have BP rechecked in 2 days.

7. The nurse is collecting data for a patient experiencing the complication of heart failure from hypertension. Which of the following findings would the nurse expect for this patient? Select all that apply.
   1. Abnormal hair growth pattern on face
   2. Distended jugular veins in semi-Fowler’s position
   3. Pain in the right hand when writing
   4. Depression from taking BP medication
   5. Bilateral ankle edema

8. The nurse is reinforcing medication teaching for a patient. The nurse would include which of the following instructions to a patient receiving a diuretic?
   1. Change positions slowly.
   2. Eliminate salt in your diet.
   3. Take your medication before bed.
   4. Empty your bladder after taking the first dose.

9. The nurse is collecting data at a follow-up visit for a patient with hypertension. Which of the following data would best indicate to the nurse that the patient’s BP therapy has been successful?
   1. Weight decreased by 3 pounds.
   2. Diary of dietary intake is within suggested diet.
   3. BP is less than 120/80 mm Hg.
   4. Patient reports walking 30 to 40 minutes daily.

Answers can be found in Appendix C.

LEARNING OUTCOMES

1. Explain the pathophysiology, etiology, signs and symptoms, and diagnostic tests for each of the valvular disorders.
2. Plan nursing care for a patient with a valvular disorder.
3. Compare and contrast the differences between commissurotomy, annuloplasty, and valve replacement.
4. Identify postoperative complications that can occur for the two types of cardiac valve replacements.
5. Explain the pathophysiology, etiology, signs and symptoms, diagnostic tests, therapeutic measures, and nursing care for infective endocarditis, pericarditis, and myocarditis.
6. Explain the pathophysiology, etiology, signs and symptoms, complications, diagnostic tests, therapeutic measures, and nursing care for dilated, hypertrophic, and restrictive cardiomyopathy.
7. Explain the pathophysiology, etiology, signs and symptoms, complications, diagnostic tests, and therapeutic measures for thrombophlebitis.
8. List risk factors and prevention measures for thrombophlebitis.
Within the normal heart, blood flows in one direction because of the presence of heart valves. There are four valves in the heart: mitral, tricuspid, pulmonic, and aortic (see Fig. 21.2). The chordae tendineae and papillary muscles are attachment structures for both the mitral and tricuspid valves. They ensure that these valves close tightly.

Damage to the valves or their surrounding structures can result in abnormal valvular functioning (Fig. 23.1). The valves of the left side of the heart are most commonly affected. Forward blood flow is hindered if the valve is narrowed, or stenosed, and does not open completely. If the valve does not close completely, blood backs up; this is referred to as **regurgitation** or **insufficiency**. The abnormal blood flow increases the workload of the heart and increases the pressures in the affected heart chamber. Valvular damage may result from congenital defects, **rheumatic fever**, or infections.

Rheumatic fever occurs as an autoimmune reaction to an upper respiratory (sore throat) group A beta-hemolytic streptococci infection. Two to 3 weeks after the streptococcal infection, rheumatic fever occurs. Although rheumatic fever can occur at any age, it typically occurs between ages 5 and 15. Rheumatic fever and subsequent rheumatic heart disease and valvular damage can be prevented by detecting and treating streptococcal infections promptly with penicillin. A throat culture is used to diagnose a streptococcal infection at the time of the infection. It is a rare complication of strep throat in the United States.

Signs and symptoms include polyarthritis, subcutaneous nodules, **chorea** (brief, rapid, uncontrolled movements), carditis, fever, arthralgia, and pneumonitis. Rheumatic heart disease may not be evident for years after rheumatic fever.

Valvular disorders are summarized in Table 23.1 and discussed in more detail in the following sections.

---

**Mitral Valve Prolapse**

**Pathophysiology**

During ventricular systole, as pressure in the left ventricle rises, the flaps of the mitral valve normally remain closed and

---

**LEARNING TIP**

The opening of a stenosed valve and an insufficient valve look very similar, and the results of extra blood building up in a chamber are the same (see Fig. 23.1). However, the pathophysiology is different. Think of what the defect is in each disorder to understand why the blood is building up in that particular chamber.

A stenosed valve does not open fully which does not allow the heart chamber to empty normally causing blood to build up in that chamber. Therefore, mitral **stenosis** does not allow the left atrium to empty easily, so blood builds up in the left atrium.

An insufficient valve does not close fully, allowing blood to flow back into the chamber that is supposed to empty. Blood continues to build up in that chamber as a result. For example, mitral insufficiency allows blood to backflow from the left ventricle into the left atrium after the left atrium has emptied, resulting in blood buildup in the left atrium.

---

**Mitral Valve Prolapse**

**Pathophysiology**

During ventricular systole, as pressure in the left ventricle rises, the flaps of the mitral valve normally remain closed and

---

**LEARNING TIP**

The opening of a stenosed valve and an insufficient valve look very similar, and the results of extra blood building up in a chamber are the same (see Fig. 23.1). However, the pathophysiology is different. Think of what the defect is in each disorder to understand why the blood is building up in that particular chamber.

A stenosed valve does not open fully which does not allow the heart chamber to empty normally causing blood to build up in that chamber. Therefore, mitral **stenosis** does not allow the left atrium to empty easily, so blood builds up in the left atrium.

An insufficient valve does not close fully, allowing blood to flow back into the chamber that is supposed to empty. Blood continues to build up in that chamber as a result. For example, mitral insufficiency allows blood to backflow from the left ventricle into the left atrium after the left atrium has emptied, resulting in blood buildup in the left atrium.

stay within the atrioventricular junction. In mitral valve prolapse (MVP), however, one or both flaps bulge backward into the left atrium (like a parachute) during systole. This can happen when one flap is too large or if a defect occurs in the chordae tendineae that secure the valve to the heart wall. If the bulging flaps do not fit together, blood can leak backward into the left atrium (mitral regurgitation). Increased pressure on the papillary muscles results in ischemia within the muscle, causing further dysfunction of the mitral valve.

**Etiology**

MVP can be due to a hereditary collagen tissue disorder with unknown etiology, an infection damaging the mitral valve, ischemic heart disease, or cardiomyopathy. MVP is the most common form of valvular heart disease. It typically occurs in women, mainly from ages 15 to 30, who are thin and have slight chest deformities.

**Signs and Symptoms**

Most patients with MVP do not have symptoms, and prognosis is very good (see Table 23.1). MVP severity ranges from having a murmur to chordae tendineae rupture with mitral regurgitation. The murmur, which is best heard at the heart apex, begins midystolic and becomes more intense until the end of systole. Symptoms may include atypical chest pain not related to exertion, dysrhythmias causing palpitations, dizziness or syncope, fatigue, dyspnea, or anxiety.

**Complications**

Rare complications include mitral regurgitation, dysrhythmias, heart failure (HF), or infective endocarditis.

**Diagnostic Tests**

Auscultation for a click caused by the stress on the chordae tendineae or valve leaflets when they prolapse, or a murmur (if blood is leaking backward), is the first diagnostic step for MVP. Other diagnostic tests are used when MVP is suspected (Box 23-1). A normal electrocardiogram (ECG) is usually seen with MVP, although in verted (downward) T waves (indicating ischemia) may be seen (see Fig. 25.7). A two-dimensional echocardiogram with Doppler can show valve abnormalities and identify mitral regurgitation from MVP. For more severe cases, cardiac catheterization can show the bulging flaps of the mitral valve on a coronary angiogram.

**Therapeutic Measures**

Unless patients have severe mitral regurgitation, MVP is a benign disorder. No treatment is needed unless symptoms are present (Box 23-2). The severity of MVP and symptoms produced determine the treatment used. A healthy lifestyle, including a good diet, exercise, stress management, and avoidance of stimulants and caffeine, can be important to prevent symptoms. Beta blockers reduce the heart rate and may help relieve chest pain. Aspirin or anticoagulants may be ordered to help prevent formation of blood clots on the valve. Surgical repair or replacement of the valve can be done for severe cases of MVP. (See Box 23-2 and the surgical interventions section later in the chapter.)

**CRITICAL THINKING**

Mrs. Tepley

Mrs. Tepley, age 32, has MVP and reports palpitations whenever she experiences stress. She drinks three cups of coffee daily.

1. What might you hear when auscultating Mrs. Tepley’s heart sounds?
2. Why does Mrs. Tepley experience palpitations? Would experiencing palpitations make you fearful?
3. What patient-centered information does Mrs. Tepley need to manage her MVP?

Suggested answers are at the end of the chapter.

Mitral Stenosis

Pathophysiology

Mitral stenosis results from thickening of the mitral valve flaps and shortening of the chordae tendineae, causing narrowing of the mitral valve opening. Older patients with mitral stenosis usually have calcification and fibrosis of the mitral valve flaps. The narrowed opening obstructs blood flow from the left atrium into the left ventricle. The left atrium enlarges to hold the extra blood volume caused by the obstruction. As a result of this increased blood volume, pressure rises in the left atrium. Pressures then rise in the pulmonary circulation and the right ventricle as blood volume backs up from the left atrium. The right ventricle dilates to handle the increased volume. Eventually the right ventricle fails from this excessive workload, reducing the blood volume delivered to the left ventricle and subsequently decreasing cardiac output.

Etiology

The major cause of mitral stenosis is rheumatic fever. It often takes two to four decades after the illness for symptoms to appear. Because rheumatic fever is rare in developed nations, less mitral stenosis is being seen except in older adults who were exposed to rheumatic fever as children. Mitral stenosis is still a problem in underdeveloped areas where rheumatic fever still occurs. Less common causes include congenital defects of the mitral valve, tumors, rheumatoid arthritis, systemic lupus erythematosus, and calcium deposits.

Signs and Symptoms

Patients may be asymptomatic (see Table 23.1). A click or low-pitched murmur may be heard. This murmur is a rumbling sound over the heart apex during diastole and is more pronounced right before systole. Pulmonary symptoms, such as exertional dyspnea, cough, hemoptysis (bloody sputum), and respiratory infections can occur. Fatigue, intolerance to activity, dizziness, or syncope result from decreased cardiac output. Edema of ankles and feet may be present. Palpitations from atrial flutter or fibrillation caused by atrial enlargement and chest pain from decreased cardiac output may be experienced.

Complications

Emboli can form from the stasis of blood in the left atrium and may cause stroke and seizures. If the right ventricle fails, symptoms related to HF are seen (see Chapter 26). Pulmonary edema may develop from the backup of blood into the lungs.

Diagnostic Tests

Mitral stenosis is diagnosed with data from the patient history and physical examination and findings from diagnostic tests (see Box 23-1). The ECG shows enlargement of the left atrium and right ventricle and changes in the P wave form (see Fig. 25.2). Atrial flutter or fibrillation may be seen (see Chapter 25). A chest x-ray examination confirms enlargement of the affected heart chambers. Transthoracic two-dimensional color flow Doppler echocardiography and Doppler ultrasound are the noninvasive gold standard for evaluation of valvular disease. They show the narrowed mitral valve opening and decreased motion of the valve. Computed tomography (CT) scan and magnetic resonance imaging (MRI) may be done. A cardiac catheterization is typically done only if needed to validate unclear echocardiography results for preoperative evaluation or postprocedure for symptom recurrence.

Therapeutic Measures

No treatment is needed if symptoms are not present. Monitoring of the stenosis is done to provide invasive treatment if needed. Anticoagulants are given to patients at risk of development of emboli from stasis of blood in the atrium. Atrial fibrillation, an irregular heart rhythm, may develop and require treatment. For HF, symptoms are treated with medications (see Chapter 26).

For less severe cases, percutaneous balloon valvuloplasty, which uses a balloon to dilate the stenosed heart valve, is done in a cardiac catheterization lab (Fig. 23.2). Surgical treatment can include valvular repair (valvuloplasty), but mitral valve replacement is typically needed (Fig. 23.3; see Box 23-2).

Mitral Regurgitation

Pathophysiology

Mitral regurgitation, or insufficiency, is the incomplete closure of the mitral valve leaflets. It allows backflow of blood into the left atrium with each contraction of the left ventricle. This blood is then extra volume that is added to the incoming blood from the lungs. With chronic mitral regurgitation, the increase in blood volume dilates and increases pressure in the left atrium. In response to the extra blood volume delivered by the left atrium, the left ventricle compensates by dilating. If the compensatory mechanism of dilation is inadequate, pressures rise in the pulmonary circulation and then in the right ventricle as blood volume backs up from the left atrium. The left ventricle and eventually the right ventricle may fail from this increased strain.

FIGURE 23.2 Percutaneous balloon valvuloplasty.
Mechanical mitral valve

FIGURE 23.3 Mitral valve replacement with mechanical valve.

Etiology
Causes of mitral regurgitation include rheumatic heart disease, endocarditis, rupture or dysfunction of the chordae tendineae or papillary muscle, MVP, hypertension, myocardial infarction (MI), cardiomyopathy, annulus calcification, aging, or congenital defects.

Signs and Symptoms
Initially, patients may be asymptomatic; however, symptoms may develop gradually and are similar to those of mitral stenosis (see Table 23.1). A murmur begins with S₁ (first heart sound) and continues during systole up to S₂ (second heart sound). Exertional dyspnea (shortness of breath), fatigue, syncope (feeling faint), cough, and edema may occur. Palpitations and an irregular pulse due to atrial fibrillation may result. Weakness from decreased cardiac output occurs if the left ventricle begins to fail. If acute mitral regurgitation develops, as in papillary muscle rupture following MI, pulmonary edema and shock symptoms will be exhibited.

Complications
Atrial fibrillation may develop from the enlargement of the left atrium. Pulmonary hypertension or heart failure may occur (see Chapter 26). Endocarditis is a risk due to the damaged valve.

Diagnostic Tests
A patient history and physical examination are done. The ECG shows enlargement of the left atrium and left ventricle and changes in the P wave (see Fig. 25.2). Atrial flutter or fibrillation may be seen. A chest x-ray examination confirms hypertrophy of the affected heart chambers. Two-dimensional echocardiography with Doppler or transesophageal echocardiography shows left atrial enlargement and regurgitation of blood. Cardiac MRI may be used for some people to determine treatment approaches. Cardiac catheterization further identifies regurgitation effects.

Therapeutic Measures
Without symptoms, there is no general medical treatment. Angiotensin-converting enzyme (ACE) inhibitors are often used to reduce afterload. If atrial fibrillation with rapid heart rate is present, it can be controlled with digitalis, calcium channel blockers, or beta blockers. Anticoagulants are used for emboli prevention. Symptoms of HF are treated with therapies for HF (see Chapter 26). When symptoms develop or surgery is indicated to prevent further left ventricular dysfunction, mitral valve repair or replacement is done. For acute mitral regurgitation, emergency surgery may be needed (see Box 23-2).

Aortic Stenosis
Pathophysiology
Blood flow from the left ventricle into the aorta is obstructed through the stenosed aortic valve. The opening of the aortic valve may be narrowed from thickening, scarring, calcification, or fusing of the valve’s flaps. To compensate for the difficulty in ejecting blood into the aorta, the left ventricle contracts more forcefully. In chronic stenosis, the left ventricle hypertrophies to maintain normal cardiac output. As narrowing increases, the compensatory mechanisms are unable to continue and the left ventricle fails to move blood forward, resulting in decreased cardiac output and HF.

Etiology
The major causes of aortic stenosis are congenital defects or rheumatic heart disease. Calcification of the aortic valve can be related to aging and occurs after age 60. Aortic stenosis is the most commonly acquired valvular heart disease in adults. As the population ages, it is expected to increase in prevalence.

Signs and Symptoms
Many years or decades may pass before signs or symptoms of aortic stenosis are observed (see Table 23.1). When symptoms do occur, evaluation is essential because the disease can progress dramatically. If the mitral valve is also diseased, signs and symptoms can appear earlier.

Angina pectoris (chest pain) is the primary symptom that occurs as a result of a lack of oxygen to the myocardium. In the young patient, angina indicates severe obstruction.

Other signs and symptoms include a murmur, syncope from dysrhythmias or decreased cardiac output, and HF signs and symptoms. The murmur is a systolic murmur that begins just after the first heart sound, increasing in intensity till midsystole, then decreasing and ending right before the second heart sound. Orthopnea, dyspnea on exertion, and fatigue are indicators of left ventricular failure, resulting in pulmonary edema and right-sided heart failure.

Complications
HF, life-threatening dysrhythmias, or endocarditis can occur
Diagnostic Tests
ECG usually shows enlargement of the left ventricle and left atrium. A chest x-ray examination confirms hypertrophy of the left ventricle and calcification of the aortic valve. Left atrial enlargement may be seen but occurs primarily when mitral stenosis is also present. Two-dimensional and Doppler echocardiography show thickening of the left ventricular wall, impaired movement of the aortic valve, and the severity of the disease. Cardiac catheterization will show elevated left ventricular pressure and decreased cardiac output.

Therapeutic Measures
Generally, the treatment of choice is valve replacement because of the risk of sudden death when severe symptoms are present (see Box 23-2). If mechanical valves are used, they require lifelong anticoagulation. For older adults, biological valves are usually used because they do not require anticoagulation therapy and last about 12 years. For those considered too high risk for traditional open-heart surgery, an aortic valve implantation can be done with a catheter via the femoral artery (visit www.medtronic.com to view this procedure—Medtronic CoreValve® system). Valvotomy (expansion of a balloon to open the mitral valve) is used only for those who are unable to have valve replacement.

Symptoms of HF are treated. Medications that reduce the contractility of the heart and subsequently cardiac output are avoided to prevent further HF.

CRITICAL THINKING

Mrs. Pryor

Mrs. Pryor, age 48, has aortic stenosis and is admitted to the hospital with angina. She had an episode of syncope 2 days ago. She reports that she tires easily.

1. Mrs. Pryor asks what aortic stenosis is. What should the nurse tell her, and how should it be documented?
2. Why might Mrs. Pryor be experiencing angina?
3. What nursing care related to safety needs is important to include in Mrs. Pryor’s plan of care? Think of how you would feel knowing you will continue to have episodes of syncope and fatigue. What concerns would you have regarding completing your activities of daily living?
4. What nursing diagnoses and care are relevant for Mrs. Pryor’s report of being tired?
5. Digoxin (Lanoxin) 0.25 mg is prescribed for Mrs. Pryor. Digoxin is available in 0.125-mg tablets. How many tablets will the nurse give?

Complications
Endocarditis is a risk due to the damaged valve. HF may occur.

Diagnostic Tests
The ECG shows left ventricle hypertrophy, ST-segment depression (see Fig. 25.10), and T-wave inversion (see Fig. 25.7) in some leads. A chest x-ray confirms hypertrophy of the left ventricle and aorta. With severe regurgitation, left atrial enlargement may also be seen. An echocardiogram, Doppler echocardiography, or transesophageal echocardiography show an enlarged left ventricle and severity of the aortic regurgitation. Cardiac catheterization reveals elevated left ventricular diastolic pressure and, with contrast injection, shows the regurgitation of blood into the left ventricle.

Aortic Regurgitation

Pathophysiology
The aortic valve cusps may be scarred, thickened, or shortened in chronic aortic regurgitation. A backflow of blood from the aorta into the left ventricle occurs if the aortic valve cusps do not close completely. The left ventricle’s blood volume increases with this backflow of blood that is in addition to the normal flow of blood from the left atrium. To handle the increased volume, the left ventricle compensates with dilation and hypertrophy to deliver a stronger contraction. This stronger contraction ejects more blood volume with each beat to maintain cardiac output. Over time, the heart’s contraction is not effective, and the left ventricle fails, causing a cardiac output drop and pulmonary edema.

Etiology
Congenital defects, aging, rheumatic heart disease, syphilis, severe hypertension, and ankylosing spondylitis can cause aortic regurgitation. An acute cause of aortic regurgitation may be endocarditis or aortic dissection.

Signs and Symptoms
Symptoms may not become apparent for many years with chronic aortic regurgitation (see Table 23.1). Initially, the patient may report feeling a forceful heartbeat that is more pronounced when lying down. Also, palpitations and pounding in the head may be experienced. Then exertional dyspnea, fatigue, and worsening levels of dyspnea (orthopnea, paroxysmal nocturnal dyspnea) occur after years of progressive valvular dysfunction. A murmur is heard during diastolic after the second heart sound. The palpated pulse is forceful and then quickly collapses (Corrigan’s pulse). The diastolic blood pressure decreases to widen the pulse pressure. This compensates for an increase in systolic blood pressure. Angina pectoris may occur late. The angina is atypical, often happening at rest or at night along with diaphoresis, when a lower pulse rate results in delivery of less oxygen to the myocardium. Even usually symptoms of HF develop if the left ventricle fails. In acute dysfunction, profound symptoms of pulmonary distress, chest pain, and shock symptoms occur.
Chapter 23  Nursing Care for Valvular, Inflammatory, Infectious Cardiac or Venous Disorders

**Therapeutic Measures**

Treatment with vasodilator therapy may be useful for some patients to reduce systolic blood pressure and subsequently cardiac workload until surgery is needed. Occasionally, surgical valve repair can be done, but valve replacement is typically needed when symptoms develop (see Box 23-2).

**Nursing Process for the Patient With a Cardiac Valvular Disorder**

**Data Collection**

A history is obtained that includes information presented in Table 23.2. Vital signs are measured and recorded. Heart sounds are auscultated to detect murmurs. Any signs and symptoms of HF are noted and reported (see Chapter 26).

**Nursing Diagnoses, Planning, Interventions, and Evaluation**

The major nursing diagnoses for all valvular disorders are the same and include those for HF as well, if symptoms of HF are present. See “Nursing Care Plan for the Patient With a Cardiac Valvular Disorder.”

**Patient Education**

Education, an important nursing intervention, promotes understanding of the valvular disorder, health maintenance, prevention of complications, and early recognition of symptoms so that medical care can be sought. For older adult patients, it is important to include caregivers or family members in teaching sessions to assist with understanding of the information being taught. Teaching is provided for medications the patient is taking. If the patient is on anticoagulants for atrial fibrillation or mechanical valve replacement, medical identification should be used, and monthly appointments to check international normalized ratio (INR)/prothrombin time (PT) values should be kept.

Information on endocarditis prevention is essential for patients with most valvular problems. Damaged cardiac valves are prone to developing infection from organisms such as *Streptococcus viridans* or *Staphylococcus epidermidis*. During invasive procedures in which bleeding is possible, these organisms can enter the circulation, attach to damaged valves, and multiply. Patients should discuss with their health care provider (HCP) the American Heart Association guidelines for prophylactic antibiotics to prevent endocarditis (see the prevention section for endocarditis later in this chapter).

**Cardiac Valve Repairs**

A balloon valvotomy opens a stenosed heart valve. A balloon catheter is inserted through the diseased valve and then inflated to open the stenosed valve leaflets. For mitral valve valvoplasty, the balloon catheter is inserted via the venous circulation into

| TABLE 23.2 DATA COLLECTION FOR PATIENTS WITH CARDIAC VALVULAR DISORDERS |
|---------------------------------|---------------------------------|
| **Data Collection**             | **Subjective Data**             |

</tbody>
</table>
atriotomy (incision into the atrium) is made to expose the valve. The valve cusps are either incised with a knife or broken apart with a dilator. The atrium is sewn closed, CPB is discontinued, and surgery continues as described in Chapter 21. Commissurotomy is most commonly performed on the mitral valve. 

**Annuloplasty** is the repair or reconstruction of the valve flaps or annulus. It may in volve the use of prosthetic rings. The mitral valve is the most common valve repaired in this way. Sutures or a ring may be placed in the valve annulus to improve closure of the leaflets. Similar procedures are used on the tricuspid valve; however, the aortic valve is not readily repaired in this manner.

**Heart Valve Replacement**

Valves used for cardiac valve replacement may be either mechanical or biological. Research is ongoing to develop tissue engineered heart valves. Biological (tissue) valves come from xenograft (porcine [pig] and bovine [cow]) or allograft (human donor) (see “Cultural Considerations”).

Allografts are available in limited numbers because they rely on donors. An autograft (Ross procedure) uses the patient’s own pulmonary valve to replace the removed aortic valve; an allograft (human donor) pulmonary valve then replaces the patient’s pulmonary valve. Visit www.lifenet.org for more information on allografts.

For mitral valve replacement, a left atriotomy is made after the patient is on CPB. For an aortic valve replacement, an incision is made above the right coronary artery in the aorta. Then in either valvular procedure, the diseased valve is excised and the new valve sutured in place. The incision is closed, and surgery then continues as described in Chapter 21.

**Complications of Valve Replacement**

Tissue valves have a low incidence of thrombus formation and do not require lifelong anticoagulant therapy, but they do last as long as mechanical valves because of degenerative changes and calcification. Mechanical valves are durable (lasting 20–30 years) but create turbulent blood flow, requiring lifelong anticoagulant therapy to prevent blood clots (Fig. 23.4). Anemia from hemolysis of red blood cells (RBCs) as they come in contact with mechanical valve structures can occur. Also endocarditis can occur due to microorganisms growing on the valve leaflets or the sewing ring of mechanical valves. These growths can make valves incompetent or break off to become emboli.

**Nursing Process for the Preoperative Cardiac Surgery Patient**

**DATA COLLECTION.** Baseline data collection is important for postoperative comparison and to begin discharge planning. Pain control needs and circulatory status are essential items. Results of diagnostic laboratory tests, x-ray examinations, and other studies are also significant. Typing and crossmatching for ordered units of blood is done.

**NURSING DIAGNOSES, PLANNING, INTERVENTIONS, AND EVALUATION.** See the “Nursing Process for Preoperative Patients” in Chapter 12.

**Nursing Process for the Postoperative Cardiac Surgery Patient**

After cardiac surgery, the patient goes to an intensive care unit (ICU) or cardiac universal bed unit (CUB). In the ICU, cultural considerations are important for religious patients. Because the pig is considered a forbidden animal to religious Jews and Muslims, only bovine, synthetic, or human valves should be used for these patients. Because the cow is sacred among Hindus, only porcine, synthetic, or human valves should be used for Hindu patients.
the patient is monitored for 1 to 2 days. As recovery progresses, the patient is transferred to a step-down or general surgical unit for continued cardiac monitoring. In the CUB unit, the patient recovers in the same room until discharge, which avoids transfers to other units and increases continuity of care.

**DATA COLLECTION.** The patient is accompanied to ICU/CUB by the anesthesiologist, who gives the nurse a report of the procedure, complications, and hemodynamic and ventilatory management of the patient. The patient is connected to a cardiac monitor and mechanical ventilator for up to 24 hours. The patient is placed under a warming device, such as a forced air blanket, as needed.

A head-to-toe assessment of the patient, including dressings, tubes (chest and, nasogastric tube, urinary catheter) and intravenous (IV) lines, is performed. Of importance are signs of a wakening, shivering, pain, lung and heart sounds, and palpation of the entire chest and neck to detect crepitus (air in the subcutaneous tissue from opening the chest). Trends in cardiac output are monitored. Body temperature is continuously monitored if warming measures are used. Warming is discontinued when the core body temperature nears 98.6°F (37°C). Warming should occur slowly to avoid peripheral vasodilation, which can result in shock. While being rewarmed, patients are assessed for shivering, which may be felt as a fine vibration at the mandibular angle of the jaw. Shivering greatly increases cardiac oxygen needs. Paralyzing agents given with narcotics eliminate shivering. Complete blood count (CBC), electrolytes, coagulation studies, and arterial blood gases (ABGs) are monitored.

After the initial transfer assessment, vital signs, oxygen saturation, and cardiac pressures are monitored and recorded every 15 to 30 minutes, with decreasing frequency as the patient stabilizes. Input and output (I&O) is measured. A 12-lead ECG is done to detect perioperative MI. A chest x-ray examination is done to check central line and endotracheal tube placement and to detect a pneumothorax or hemothorax, diaphragm elevation, or mediastinal widening from bleeding. At this point, the family can see the patient.

Awakening with many questions, strange auditory and tactile sensations, and the inability to speak are frightening and frustrating to the patient. Give explanations regarding procedures in simple terms. Keeping eye contact with the patient and using touch appropriately can be soothing to the patient. If lip reading is unsuccessful, use simple closed-ended questions, nonverbal gestures, communication boards, or magic slates.

After cardiac surgery, pain is monitored in relation to the patient’s preoperative anginal or infarction-associated pain. Chest pain after surgery can be frightening. Knowing that chest pain can occur from the surgical incision rather than from anginal or MI pain is comforting to the patient.

**NURSING DIAGNOSSES, PLANNING, INTERVENTIONS, AND EVALUATION.** Nursing diagnoses for postoperative cardiac surgery are discussed in the “Nursing Care Plan for the Postoperative Patient Undergoing Cardiac Surgery.” Additional general postoperative nursing care is discussed in Chapter 12.

---

**NURSING CARE PLAN for the Postoperative Patient Undergoing Cardiac Surgery**

**Nursing Diagnosis:** Pain related to sternotomy or pericarditis

**Expected Outcomes:** The patient will state that pain is relieved or tolerable. Patient will be able to rest and perform respiratory treatments.

**Evaluation of Outcomes:** Does patient state pain is within acceptable levels? Is patient able to rest and perform respiratory therapies?

<table>

### Nursing Diagnosis: Risk for Infection related to inadequate primary defenses from surgical wound

**Expected Outcome:** The patient will remain free from infection.

**Evaluation of Outcome:** Does patient remain free from infection?
NURSING CARE PLAN for the Postoperative Patient Undergoing Cardiac Surgery—cont’d

**Intervention** Practice excellent hand hygiene, and always cleanse stethoscope with ethanol-based cleanser or alcohol between patients. **Rationale** Hands and stethoscopes carry infectious agents. **Evaluation** Are infectious preventive techniques used? Does patient remain free from infection?

**Intervention** Observe incision for signs and symptoms of infection, which are redness, warmth, fever, and/or edema. **Rationale** Redness, warmth, fever, and swelling indicate the body’s response to an invading pathogen. **Evaluation** Are signs and symptoms of infection present?

**Intervention** Monitor drainage and maintain drains. **Rationale** Drains remove fluid from the surgical site to prevent infection development. **Evaluation** Are drainage amount and color normal for procedure? Are drains functioning?

**Intervention** Maintain sterile technique for dressing changes. **Rationale** Sterile technique reduces infection development. **Evaluation** Is incision free of signs and symptoms of infection?

**Intervention** Monitor and report abnormal findings for temperature, lung sounds, sputum, and urine consistency. **Rationale** Low-grade (immunosuppressed) or high-grade fever, crackles, yellow-green sputum color, or cloudy urine can indicate infection. **Evaluation** Is the patient’s temperature WNL, and are lung sounds, sputum, and urine clear?

INFLAMMATORY AND INFECTIOUS CARDIAC DISORDERS

The layers of the heart—the endocardium, pericardium, and myocardium (Fig. 23.5)—can become inflamed or infected, leading to endocarditis, pericarditis, and myocarditis, respectively.

**Infective Endocarditis**

**Infective endocarditis** (IE) is an infection of the endocardium that mostly occurs in hearts with artificial or damaged valves. Men develop IE more often than women, as do older adults compared with younger.

**Pathophysiology**

Cardiac defects result in turbulent blood flow that erodes the normally infection-resistant endocardium. IE begins when the invading organism (most commonly a bacteria but possibly a fungi or other organism) attaches to eroded endocardium where platelets and fibrin deposits have formed a vegetative lesion. Then more platelets and fibrin cover the multiplying organism. This covering protects the microbes, reducing the ability to destroy them. Damage to valve leaflets occurs as the vegetations grow. As blood flows through the heart, these vegetations may break off and become emboli.

Damaged valves from conditions such as MVP with regurgitation, rheumatic heart disease, congenital defects, and valve replacements are especially prone to bacterial invasion. The mitral valve is the valve most commonly infected, with the aortic valve being second. HF may result from valve damage, especially of the aortic valve.

**Etiology**

Risk factors include the following:

- Compromised immune system
- Artificial heart valve

![FIGURE 23.5 Layers of the heart.](image-url)
• Congenital or valvular heart disease
• History of endocarditis
• IV drug use
• Gingival gum disease.

Prevention
Dental disease may be a contributing factor to IE, so daily oral care and regular dental care is an important preventive measure. Antibiotic prophylaxis guidelines have been updated. Before a dental procedure, the American Heart Association (2014) now recommends that only individuals with an artificial heart valve or a valve repaired with artificial material, a history of endocarditis, a heart transplant with abnormal valve function, or specific congenital heart defects receive antibiotics. Prophylaxis for procedures on the genitourinary or gastrointestinal (GI) tract or for most people who have orthopedic implants is no longer recommended.

Signs and Symptoms
The onset of symptoms can be rapid or slow. Fever (99°–103°F [37.2°–39.4°C]) is a common sign, although the older adult may be afebrile (Table 23.3). Chills, aching muscles and joints, fatigue, dyspnea, cough, edema, and hematuria may occur. A new or different murmur is heard with valvular damage. Splinter hemorrhages may be seen in the distal nailbed (black or red-brown longitudinal short lines). Petechiae (tiny red or purple flat spots) resulting from microembolization of the vegetation may occur on mucous membranes, conjunctivae, or skin (Fig. 23.6). Jane way lesions (small, painless red-blue lesions on palms and soles) are an acute finding. Osler’s nodes (small, painful nodes on fingers and toes) from cardiac emboli are a late finding (Fig. 23.7). Have you ever seen petechiae or palpated an Osler’s node? Look for the opportunity in clinical to see petechiae, Janeway lesions, or an Osler’s node.

Complications
Vegetative emboli can be a major complication of IE. If organ embolization occurs, signs and symptoms that reflect the organ that was affected by the emboli are seen. Brain emboli may produce changes in level of consciousness or stroke. Kidney emboli cause pain in the flank area, hematuria, or renal failure. Emboli in the spleen cause abdominal pain. Emboli in the small blood vessels can impair circulation in the extremities. Pulmonary emboli result in sudden dyspnea, cough, and chest pain.

Heart structures can be damaged or destroyed by IE. Stenosis (narrowing) or regurgitation (leakage) of a heart valve may also result. As the infection progresses and causes more damage to heart structures, HF may occur. Abscesses may also develop in the heart or other parts of the body.

Diagnostic Tests
Table 23.3 lists diagnostic tests for IE. Positive blood cultures identify the causative organism, and echocardiography shows cardiac effects.

| TABLE 23.3 INFECTIVE ENDOCARDITIS SUMMARY |
| Signs and Symptoms | Fever |
| | Chills |
| | Heart murmur |
| | Night sweats |
| | Fatigue |
| | Weight loss |
| | Weakness |
| | Aching in abdomen, joints, muscles, back |
| | Nailbed splinter hemorrhages |
| | Petechiae |

| | Transesophageal echocardiography |
| | CBC |
| | Chest x-ray |
| | ECG |

| Therapeutic Measures | Acute therapy: |
| | IV antimicrobial medications such as penicillin, vancomycin, amphotericin B |
| | Antipyretics |
| | Rest |
| | Valve replacement |
| | Prophylactic antibiotic therapy per high-risk infective endocarditis criteria |

| Complications | Emboli |
| | Heart failure |
| | Abscesses |

| Priority Nursing Diagnoses | Activity Intolerance related to reduced oxygen delivery from decreased cardiac output |
| | Decreased Cardiac Output related to impaired valvular function or heart failure |
| | Ineffective Tissue Perfusion related to emboli |

Note. CBC = complete blood count; ECG = electrocardiogram.

Therapeutic Measures
Initial treatment begins with hospitalization. An antimicrobial drug is selected that will destroy the organism identified by the blood culture. For bacterial infections, penicillin (or vancomycin for those allergic to penicillin) is commonly used. These medications are given IV over a period.
of 4 to 6 weeks, often once a day. A lengthy course of high-dose antibiotics is needed to penetrate the vegetations to reach all of the microbes inside to kill them. Rest and supportive symptom care are also used. If afebrile and without complications, the patient is discharged to continue IV antibiotic therapy at home. Response to the drug is monitored by the home care nurse and laboratory testing.

Surgical replacement or repair of valves is done for severely damaged heart valves, prosthetic valve infection, recurrent infection, multiple emboli from damaged valves, or HF. Antimicrobial therapy continues after surgery.

**NURSING CARE PLAN for the Patient With Infective Endocarditis**

**Nursing Diagnosis:** Decreased Cardiac Output related to impaired valvular function or heart failure as manifested by activity intolerance

**Expected Outcome:** The patient will have adequate cardiac output as evidenced by vital signs WNL, no dyspnea, and minimal fatigue in response to activity.

**Evaluation of Outcome:** Are patient’s vital signs WNL with no dyspnea and minimal fatigue? Can patient participate in desired activities?

**Intervention** Assess vital signs, murmurs, dyspnea, and fatigue. **Rationale** Abnormal vital signs, dyspnea, and fatigue are indicators of cardiac output decline. **Evaluation** Are vital signs WNL with no dyspnea or fatigue?

**Intervention** Give oxygen as ordered. Measure oxygen saturation. **Rationale** Supplemental oxygen will increase oxygen level in the blood. **Evaluation** Is oxygen saturation WNL?
UNIT FIVE Understanding the Cardiovascular System

NURSING CARE PLAN for the Patient With Infective Endocarditis

**Intervention** Provide bedrest or rest periods as ordered. **Rationale** Cardiac workload and oxygen needs are reduced with rest. **Evaluation** Are vital signs WNL and no fatigue reported?

**Intervention** Elevate head of bed 45 degrees. **Rationale** Venous return to heart is reduced and chest expansion improved. **Evaluation** Are vital signs WNL and respirations easy with no reported dyspnea or use of accessory respiratory muscles?

**Intervention** Assist with activities of daily living (ADLs) as needed, providing rest periods. **Rationale** Assistance conserves energy. Cardiac workload and oxygen needs are reduced with rest. **Evaluation** Are ADLs completed? Does patient report less fatigue?

**Nursing Diagnosis:** Deficient Diversional Activity related to restricted mobility from prolonged IV therapy

**Expected Outcome:** The patient will state diversional activities are satisfying.

**Evaluation of Outcome:** Does patient participate in diversional activities? Does patient state satisfaction with activities?

**Intervention** Assess patient’s preferred activities and hobbies. **Rationale** Activity preference should be known to plan satisfactory diversional activities. **Evaluation** Are patient’s preferred activities known?

**Intervention** Plan patient’s schedule around relaxing and fun activities, using the patient’s input. **Rationale** Self-esteem is fostered with increased patient control. **Evaluation** Does patient offer input into scheduled care? Is input followed?

**Intervention** Use pet therapy. **Rationale** Individuals who interact with pets live longer and are healthier. **Evaluation** Does patient state enjoyment of pet therapy?

**Intervention** Provide a mix of physical, mental, and social activities on a rotating schedule. **Rationale** Rotating stimulating activities and visitors will keep patient interested and avoid fatigue. **Evaluation** Does patient state satisfaction in activities with no fatigue?

Pericarditis

**Pathophysiology and Etiology**

Pericarditis is an acute or chronic inflammation of the pericardium (the sac surrounding the heart). The inflammation creates a problem for the heart as it tries to expand and fill. As a result, ventricular filling is reduced, which then decreases cardiac output and blood pressure. Acute pericarditis usually resolves in less than 6 weeks. Recurrence is possible. Acute pericarditis can be caused by a variety of factors, including the following:

- Infections: viruses, bacteria, fungi, or Lyme disease
- Drug reactions
- Connective tissue disorders: systemic lupus erythematosus, rheumatic fever, or rheumatoid arthritis
- Neoplastic disease
- Postpericardiectomy (e.g., after cardiac surgery)
- Postmyocardial infarction
- Dressler syndrome (autoimmune response)
- Renal disease or uremia
- Trauma from chest injury or invasive thoracic procedures

There are several forms of chronic pericarditis. Chronic constrictive pericarditis is the result of fibrous scarring of the pericardium. The heart becomes surrounded by a thickened, stiff sac that limits the stretching ability of the heart’s chambers for filling, which may result in HF. Chronic constrictive pericarditis results from neoplastic disease and metastasis, radiation, or tuberculosis.

**Signs and Symptoms**

Chest pain is the most common symptom of acute pericarditis (Table 23.5). The pain is located substernally and over the heart and may radiate to the clavicle, neck, left scapula, or epigastric area. Typically there is an intense, sharp, creaky, grating pain that increases with deep inspiration, coughing, moving of the trunk, or lying flat. For some the pain is not as intense and is instead a dull ache. The pain may be relieved by sitting up and leaning forward. Other symptoms depend on the cause of the pericarditis and may include orthopnea, low-grade fever, fatigue, cough, and edema.

</table>

*Note: CBC = complete blood count; CT = computed tomography; ECG = electrocardiogram; MRI = magnetic resonance imaging.*

A **pericardial friction rub**—a grating, scratchy, high-pitched sound—may be heard. The rub is a result of friction from the inflamed pericardial and epicardial layers rubbing together as the heart fills and contracts. Depending on the severity of the pericarditis, the rub may be faint when auscultated or loud enough to be audible without auscultation. The rub may be heard intermittently or continuously. It is usually heard over the lower left sternal border of the chest during each heartbeat. It is present in about 50% of those with pericarditis.

Chronic constrictive pericarditis produces dyspnea and signs and symptoms of right-sided HF and may also cause atrial fibrillation.

**Diagnostic Tests**

Table 23.5 lists diagnostic tests for pericarditis. The ECG reveals ST-T wave elevation in all leads (see Fig. 25.11), which indicates cardiac injury. Echocardiogram results show **pericardial effusions** (buildup of fluid in pericardial space). Serum laboratory tests focus on causes of the pericarditis, such as an elevated white blood cell (WBC) count, indicating a bacterial or viral infection, or elevated blood urea nitrogen or creatinine levels, indicating uremia. Fluid obtained during **pericardiocentesis** (aspiration of fluid from pericardial sac) is examined to diagnose the cause. In chronic constrictive pericarditis, a CT scan or MRI may show a thickened pericardium.

**Therapeutic Measures**

Mild acute cases may resolve without treatment. The cause is determined so that appropriate treatment can be administered, such as antibiotics for bacterial infections. Bed rest is used to reduce the heart’s workload during acute symptoms. Nonsteroidal anti-inflammatory drugs (NSAIDs) or aspirin are given along with colchicine (Colsalide) to resolve inflammation and reduce pain. Corticosteroids are used if initial treatment is not effective. Hemodialysis is used to treat uremic pericarditis. If the patient is unstable, prompt intervention is required, such as an emergency pericardiocentesis.

Chronic effusive pericarditis can be treated with a pericardial window to allow continuous drainage of pericardial fluid into the pleural space. A pericardial window is created surgically by removing a portion of the outer pericardial layer.

Chronic constrictive pericarditis is treated with **pericardiectomy**, which is the surgical removal of the entire tough, calcified pericardium. Pericardiectomy relieves constriction of the heart and allows normal filling of the ventricles.

**Complications**

A pericardial effusion is the most common complication of pericarditis. A rapidly developing effusion, such as one occurring from trauma, can produce symptoms with smaller amounts of fluid than slowly developing effusions, such as pericarditis from tuberculosis, with larger amounts of fluid. The increasing fluid pressures on nearby tissue. Pressure on lung tissue can produce dyspnea, cough, and tachypnea. The heartbeat sounds distant. The body’s compensatory mechanisms attempt to maintain blood pressure.

As the fluid accumulation grows, cardiac tamponade, another complication of pericarditis, can occur. Cardiac tamponade is a life-threatening compression of the heart fluids.
Understanding the Cardiovascular System

by fluid accumulated in the pericardial sac. Cardiac output drops and, to compensate, the heart rate increases. Then blood pressure falls as compensatory mechanisms fail. The patient shows symptoms of decreased cardiac output, such as restlessness, confusion, tachycardia, and tachypnea. Jugular venous distention is present from increased venous pressure, and heart sounds are distant.

Cardiac tamponade requires immediate treatment with pericardiocentesis. The pericardium is punctured with a 16-gauge needle, and excess fluid in the pericardial sac is removed (Fig. 23.8). After the procedure, the patient is monitored for complications, such as dysrhythmias, laceration of a coronary artery, or laceration of the myocardium or pneumothorax.

Nursing Care

A patient history is obtained that includes any cardiac disease, recent infections, and current medications. Vital signs are documented, noting fever, tachycardia, as well as chest pain, pericardial friction rub, and signs of HF.

Nursing care focuses on relieving the patient’s pain and anxiety and maintaining normal cardiac function. Pain is rated and treated as ordered. Allowing the patient to assume a position of comfort by sitting up and leaning forward also relieves pain. Teaching the patient about pericarditis and its treatment relieves anxiety and allows a feeling of control by allowing the patient to make knowledgeable health care decisions.

Myocarditis

Pathophysiology and Etiology

In myocarditis, inflammation of the myocardium occurs. The amount of muscle destruction and necrosis that occurs as a result of myocarditis determines the extent of damage to the heart. The heart may enlarge in response to the damaged muscle fibers, although most cases of myocarditis are benign, with few signs or symptoms.

Myocarditis is a rare condition that most commonly develops after a viral infection. Other causes are bacteria, parasites, fungi, rickettsiae, spirochetes, medications, lead toxicity, autoimmune factors, human immunodeficiency virus (HIV), rheumatic fever, systemic lupus erythematosus (SLE), pericarditis or IE, or cardiac transplant rejection.

Signs and Symptoms

Signs and symptoms of myocarditis vary from none to severe cardiac manifestations. Fatigue, fever, pharyngitis, malaise, dyspnea, palpitations, muscle aches, GI discomfort, and enlarged lymph nodes may occur early from a viral infection. Cardiac manifestations such as chest pain or tachycardia may occur about 2 weeks after a viral infection. Occasionally, sudden death may occur.

Diagnostic Tests

A myocardial biopsy during the first 6 weeks of inflammation is the preferred diagnostic test for myocarditis, although it is positive only about 30% of the time. Echocardiogram and MRI are helpful. An ECG shows dysrhythmias, commonly sinus tachycardia. Blood tests are done, including CBC, viral antibodies, and enzyme levels that look for heart damage.

Therapeutic Measures

Treatment is aimed at the cause, if known, such as antibiotics for bacterial infections. Interventions to reduce the heart’s workload during recovery are essential and include bed rest and limited activity. Exercise increases myocardial inflammation and mortality and should be avoided until symptoms improve and inflammation is gone. The use of alcohol and tobacco should be avoided. Symptoms of HF are treated with medications such as beta blockers, ACE inhibitors, diuretics, or digoxin to reduce the heart’s workload and oxygen needs. With myocarditis, the heart is sensitive to digoxin. The patient should be monitored closely for signs of digoxin toxicity, which may include anorexia, nausea, vomiting, bradycardia, dysrhythmias, or malaise.

• WORD • BUILDING •

myocarditis: myo—muscle + kardia—heart + itis—inflammation
Nursing Care

Recent illnesses, toxin exposure, cardiac diseases, activity tolerance, and current medications are documented. Vital signs and signs of heart failure, such as jugular venous distention, peripheral edema, crackles, and dyspnea are noted.

Nursing care is aimed at maintaining normal cardiac function by monitoring vital signs, symptoms, and administering medications as ordered. Interventions to reduce fatigue include providing assistance as needed, having frequent rest periods, and teaching energy conservation methods. Reducing the patient’s anxiety and increasing his or her knowledge can be achieved by teaching about the disease. Determining diversional activities with the patient for times when activity is restricted further reduces patient anxiety.

Cardiac Trauma

Two types of cardiac trauma can occur: nonpenetrating and penetrating. Nonpenetrating injuries, or contusions, occur from blunt trauma such as motor vehicle accidents or contact sports in which direct compression or force is applied to the upper torso. Contusions may vary from small bruises to hemorrhage.

There may be few or no external injuries indicating traumatic cardiac injury. The patient may be asymptomatic or exhibit signs and symptoms identical to a MI. In severe contusions, laboratory results may show elevated creatine kinase MB (CK-MB, an enzyme) or troponin I (a protein) levels.

If bleeding into the pericardial sac occurs, cardiac tamponade can occur. If signs of shock are present, a pericardiocentesis must be performed. With its own pressure, the tamponade may seal the area of bleeding, so no cardiac decompensation occurs. In this case, only bed rest and observation are required. There are no long-term effects with most contusions. With severe contusions, however, scarring and necrosis of the myocardium may decrease cardiac output and increase the risk for cardiac rupture.

Penetrating traumas include an external injury to the chest, such as a stab or gunshot wound, or an internal injury, such as invasive lines that penetrate the cardiac muscle. Complications vary depending on the size, location, and cause of injury. Tamponade occurs from bleeding into the pericardial sac if the pericardium is sealed off by clot formation. A hemothorax develops if blood drains into the pleural space in the chest. A pneumothorax occurs if air collects in the pleural space. Signs and symptoms of hemorrhage and myocardial ischemia can be noted. Surgical repair may be indicated.

Cardiomyopathy

Cardiomyopathy is an enlargement of the heart muscle. There are three types of cardiac structure and function abnormalities in cardiomyopathy: dilated, hypertrophic, and restrictive (Fig. 23.9). A consequence of each type of cardiomyopathy can be HF (Fig. 23.10), myocardial ischemia, or MI due to reduced cardiac output. There is currently no cure. The greatest advancement for the cardiomyopathies has been in genetic research, which has identified genetic mutations that cause these diseases and are leading to better diagnosis and treatment.

Dilated Cardiomyopathy

In dilated cardiomyopathy, the size of the ventricular cavity enlarges with reduced cardiac output. Contractile function decreases as the myocardial tissue is destroyed. Blood moves more slowly from the left ventricle, which often results in blood clot formation. Dilated cardiomyopathy is the most frequent type of cardiomyopathy and one of the most frequent causes of HF. Dilated cardiomyopathy may be caused by genetics, infectious myocarditis, hypertension, heart valve disorders, myocardial infarction, chronic alcohol or cocaine use, metals such as lead, elevated iron levels, HIV, thiamine or zinc deficiencies, cardiac infections, chemotherapy, neuromuscular disorders, or other causes.

• WORD BUILDING •

cardiomyopathy: kardia—heart + myo—muscle + pathy—disease
Hypertrophic Cardiomyopathy

Hypertrophic cardiomyopathy is enlargement of the cardiac muscle wall, often of the septum and left ventricle. The hypertrophy may occur asymmetrically. It can be a hereditary disorder that is transmitted as a dominant trait. Hypertrophic cardiomyopathy causes the ventricular wall to be rigid, which decreases ventricular filling. If an enlarged septum obstructs the outflow of blood through the aortic valve, it is known as obstructive hypertrophic cardiomyopathy. Death can occur suddenly and is likely due to an abnormal heart rhythm.

Restrictive Cardiomyopathy

Restrictive cardiomyopathy impairs ventricular stretch and limits ventricular filling. Cardiac muscle stiffness is present with no ventricular dilation, although systolic emptying of the ventricle remains normal. Restrictive cardiomyopathy is the rarest form of cardiomyopathy. It may be caused by infiltrative diseases such as amyloidosis that deposit the protein amyloid within the myocardial cells, making the muscle stiff and resistant to stretching for easy ventricular filling. Treating the underlying cause may help reduce heart damage.

Signs and Symptoms

Manifestations of cardiomyopathy depend on the type of abnormality. Most patients show varying degrees of signs and symptoms of heart failure (Table 23.6). With dilated cardiomyopathy, left ventricular and then right-sided heart failure with a poor prognosis are seen. Dyspnea on exertion, orthopnea, fatigue, and sometimes atrial fibrillation occur. In hypertrophic cardiomyopathy, exertional dyspnea related to the obstruction of cardiac output is the most common symptom. Angina is not common, but atypical chest pain that occurs at rest and is not relieved with nitrates may occur. With restrictive cardiomyopathy, heart failure symptoms result from the ventricles' inability to fill during diastole. Syncope, arrhythmias, and thrombi may occur.

Diagnostic Tests

Cardiomegaly is visible on a chest x-ray examination. Echocardiography shows muscle thickness and chamber size to differentiate between the types of cardiomyopathy. Changes related to enlarged chamber size, tachycardia, and dysrhythmias can be seen on the ECG. Cardiac catheterization and biopsy may be useful as well as cardiovascular magnetic resonance. Blood tests may be done to identify infections or elevated metal or iron levels.

Therapeutic Measures

Treatment for both dilated and restrictive cardiomyopathies is palliative, aimed at managing HF and the underlying cause, if known (see Chapter 26). For dilated cardiomyopathy, treatment focuses on the symptoms of HF. ACE inhibitors, angiotensin II receptor blockers, beta blockers,
diuretics, aldosterone antagonists, and digoxin may be given. Biventricular pacing and implantable defibrillators may be used. Therapy is not very useful for restrictive cardiomyopathy. Diuretics or nitrates may be used to relieve venous congestion that occurs because of HF. However, a fine balance is needed when using these drugs so that preload is not reduced too greatly, which would worsen symptoms. Anticoagulants are given to prevent emboli formation in patients with atrial fibrillation. Antidysrhythmics or cardiovascular is used for dysrhythmias.

For obstructive hypertrophic cardiomyopathy, beta blockers and calcium channel blockers are given to slow the heart rate to allow more filling time and lessen the strength of the heart’s contraction. An antiarrhythmic agent might be used. Patients must remain hydrated at all times to maintain cardiac output.

In obstructive hypertrophic cardiomyopathy, digoxin and vasodilators are avoided because they can increase the obstruction. Strenuous exercise and athletic sports are restricted to prevent sudden death. Lower levels of exercise may be allowed. For patients in whom medical therapy is not effective, atrioventricular (AV) sequential pacemakers, implantable automatic defibrillators, or invasive procedures are considered. For those without obstruction, fewer treatment options exist. Diuretics are used to reduce elevated pressures along with beta blockers and calcium channel blockers.

If medical therapy is not successful, surgery is considered. For hypertrophied muscle, surgery to remove part of the ventricular septum (myectomy) is done to allow greater outflow of blood. Another option especially for those who are not candidates for surgery is septal ablation. In septal ablation, alcohol is delivered via a catheter to necrose and reduce septal heart wall thickness.

For severe HF, primarily in those with dilated cardiomyopathy, a heart transplant may be the only hope for survival. A ventricular assist device may be used until a donor is found. Many patients die while waiting for a donor heart because of HF. However, a fine balance is needed when using these drugs so that preload is not reduced too greatly, which would worsen symptoms. Anticoagulants are given to prevent emboli formation in patients with atrial fibrillation. Antidysrhythmics or cardiovascular is used for dysrhythmias.

Reducing anxiety is important and can be accomplished by providing education regarding procedures, as well as educating the patient about the disease and its treatment. This should provide patients with a greater sense of control and help them to make informed decisions. These patients and their families have a great need for emotional support because of the chronic nature of the disease (see Box 23-3).

### Nursing Care

A patient history is obtained that includes signs and symptoms and data collection related to family support systems because of the chronic nature of the disease. A physical assessment is done, noting vital signs and any signs or symptoms of HF.

### Nursing care focuses on maintaining normal cardiac function, increasing activity tolerance, relieving anxiety, and educating the patient about the disease and its treatment. Patients with cardiomyopathy can be very ill. Careful monitoring is done to detect complications, such as HF, emboli, or dysrhythmias. The HCP is immediately notified of problems. Home health care is often used for these patients to maintain their functional ability and reduce hospitalizations.

Maintenance of normal cardiac function includes increasing activity tolerance, planning rest periods, scheduling activities in small amounts, voiding tiring activities, and providing small meals that require less energy to digest than large meals. Patients are encouraged to avoid alcohol because it decreases cardiac function.

### Thrombophlebitis

Thrombophlebitis is the formation of a clot, followed by inflammation within a vein. Thrombophlebitis is the most common disorder of veins, with the legs being most often affected. Any superficial or deep vein in the body can be involved. Deep venous thrombosis (DVT) is the most serious form of thrombophlebitis because pulmonary emboli can result if the thrombus detaches (see Chapter 28).

### Pathophysiology

A venous thrombus is made up of platelets, RBCs, WBCs, and fibrin. Platelets attach to a vein wall, and then a tail forms as more blood cells and fibrin collect. As the tail grows, it drifts in the blood flowing past it. The turbulence of the blood flow can cause parts of the drifting thrombus to break off and become emboli that travel to the lungs.

### Etiology

Three factors, referred to collectively as Virchow’s triangle, are involved in the formation of a thrombus: stasis of blood flow, damage to the lining of the vein wall, and increased blood coagulation (Table 23.7). Venous stasis occurs when blood flow is reduced, veins are dilated, muscle contractions are decreased, or vein valves are faulty. When the wall

---

**Box 23-3 Patient Education**

**Cardiomyopathy**

Patients and families should understand the importance of the following:

- Adherence to medication regimen to prevent heart failure
- Having emergency telephone numbers readily available
- Cardiopulmonary resuscitation (CPR) training for family members
- The availability of hospice care and emotional support for families during the grieving process
of a vein is damaged, it provides a site for a thrombus to form. IV therapy and venipuncture cause trauma to the vein, and IV catheters in place longer than 48 to 72 hours increase the risk of inflammation and thrombus. Increased coagulation of the blood promotes thrombus formation. Patients on oral anticoagulants that are abruptly stopped experience increased clotting of the blood. Smoking, oral contraceptive use, and estrogen therapy also increase blood coagulation. Hematologic disorders can also lead to altered blood coagulation and increased risk of thrombus formation.

**Prevention**

Identification of risk factors for thrombosis (see Table 23.7) and patient education promote the use of interventions (discussed later) to prevent thrombosis (see “Evidence-Based Practice”). Because older adults are at increased risk for thrombus formation, a family member should also be instructed in techniques that may be difficult for the older person to perform. Dehydration should be avoided to reduce thrombus risk.

**IMMOBILITY.** People with sedentary jobs that require long periods of sitting, standing, or traveling long distances should change positions, perform knee and ankle flexion exercises, or walk at regular intervals to prevent stasis of blood. Patients on bed rest should have their legs elevated above the level of the heart, if possible, and turn every 2 hours to prevent pooling of blood. Postoperatively or in times of bed rest, active or passive range-of-motion (ROM) exercises should be done to increase blood flow. Postoperatively, early ambulation is a major preventive technique for thrombosis. Patients’ pain should be controlled to facilitate their ability to participate in early ambulation. Deep breathing aids in improving blood flow in the large thoracic veins. Smoking should be avoided because nicotine causes vasoconstriction.

**EVIDENCE-BASED PRACTICE**

**Clinical Question**

Are statins effective in preventing venous thromboembolism?

**Evidence**

A large randomized controlled trial involving 17,802 participants aged 50 years or older for men and 60 years or older for women, without a history of cardiovascular disease, a low-density lipoprotein (LDL) cholesterol level of less than 3.4 mmol/L and a high-sensitivity C-reactive protein level of 2.0 mg/L or more found that rosuvastatin (Crestor), a statin, did reduce the incidence of venous thrombosis, especially in the presence of cancer, recent trauma, hospitalization, or surgery. However, the drug did not reduce complications that occurred after diagnosis of venous thrombosis.

**Implications for Nursing Practice**

It has been shown that statins are effective in reducing venous thromboembolism.

**REFERENCE**

PROPHYLACTIC ANTIEMBOLISM DEVICES. Patients with peripheral vascular disease, those on bed rest, and those who have had surgery or trauma may use antiembolism devices to improve blood flow. Knee- or thigh-length elastic compression stockings apply pressure to the leg. They must be applied correctly to avoid a tourniquet effect. Older patients with decreased manual dexterity may need assistance. The skin should be inspected, cleansed, and moisturized daily for irritation under the stockings as ordered. Intermittent pneumatic compression (IPC) devices fill intermittently with air to move venous blood in the legs by simulating contraction of the leg muscles. They may be used in combination with elastic compression stockings. Research that compares the various preventive measures for DVT and rates of DVT in surgical patients has shown that the lowest incidence of DVT occurs with elastic compression stockings and IPC devices used together.

PROPHYLACTIC MEDICATION. Low molecular weight heparin (LMWH) is given postoperatively to prevent thrombosis (Table 23.8). Anticoagulation tests are not monitored with LMWH because of the predictability of its dose-related response. Subcutaneous heparin may also be used postoperatively to prevent thrombosis. Platelet counts must be monitored with either LMWH or heparin to detect heparin-induced thrombocytopenia.

Oral anticoagulants such as warfarin (Coumadin) can be used in the high-risk patient to decrease thrombosis. The

BE SAFE!
For prevention of thrombophlebitis:
• Teach and encourage leg exercises if patient is immobilized in bed.
• Ambulate as early as possible.
• Change IV sites every 48 to 72 hours.

</tr>
</tbody>
</table>

Note. INR = international normalized ratio; PT = prothrombin time; PTT = partial thromboplastin time.
LEARNING TIP

Before administering anticoagulants, laboratory values must be assessed to ensure patient safety.

- Normal and desired therapeutic INR values for the patient’s disorder are provided on the laboratory report. These INR values do not require calculation of a therapeutic range because the values are given on the report.
- Compare the patient’s INR value with the desired INR value to determine if it is safe to give the warfarin.
- Although INR is the preferred test for warfarin effectiveness, you might still want to know how to calculate a therapeutic range for PT. PT is measured in seconds. The normal value range gives the seconds required for a fibrin clot to form during the test. If a patient is on warfarin, the purpose is to increase the time (seconds) it takes the blood to clot.
- Because a therapy, warfarin, is being given, a PT range that safely considers the expected effects of the warfarin is needed. This is called the therapeutic range (i.e., a low and a high value). Warfarin’s therapeutic range is 1.5 to 2 times the normal PT range. To monitor the patient’s therapeutic PT, compare the patient’s result with the therapeutic range that you calculate. For example: patient’s value on warfarin: 16 seconds (sec)
  - Normal PT range: 9 to 12 seconds
  - To calculate therapeutic range, multiply: \[ \frac{1.5 \times 9 \text{ sec}}{12 \text{ sec}} \]
  - Therapeutic range: 13.5 sec to 24 sec
- Compare the patient’s value of 16 seconds with the therapeutic range of 13.5 to 24 seconds to determine that the patient’s PT value is safely within the therapeutic range.

NSAID = nonsteroidal anti-inflammatory drugs.
may also be present. Pain in the calf with sharp dorsiflexion of the foot, a classic indication known as a positive Homans’ sign, is present in less than 50% of those with thrombophlebitis and is not specific to DVT. Once a DVT is positively diagnosed, it is important to avoid performing Homans’ sign because it may cause the clot to become dislodged. Cyanosis and edema may occur if the large veins such as the vena cava are involved.

Complications

The most serious complication of DVT is pulmonary embolism, which is a life-threatening emergency (see Chapter 28). Another complication, chronic venous insufficiency, results from damage to the valves in the vein and causes venous stasis. Signs and symptoms from venous insufficiency that may appear years after a thrombus include edema, pain, brownish discoloration and ulceration of the medial ankle, venous distention, and dependent cyanosis of the leg. This condition can be difficult to treat.

Diagnostic Tests

Diagnostic tests are done to guide treatment, with venous duplex ultrasound being the primary test used (see Table 23.9).

Therapeutic Measures

The goals of treatment are to relieve pain and to prevent pulmonary emboli, thrombus enlargement, and further thrombus development. Superficial thrombophlebitis is treated with warm, moist heat; analgesics; NSAIDs; and elastic compression stockings.

Patients with a proximal DVT may be treated at home if they do not have pulmonary embolism, cardiac vascular or pulmonary disease, obesity, or renal failure and are able to adhere to follow-up care. LMWH is given subcutaneously daily or twice a day, and oral warfarin is started (see Table 23.8). Both are taken until the INR is within therapeutic range (about 5 days), then the LMWH is stopped.

Traditional medical care for some DVTs involves a hospital stay with bed rest, elevating the leg above heart level for 5 to 7 days; warm, moist heat; elastic compression stocking (initially on unaffected leg only until acute symptoms are gone on affected leg); and anticoagulants. An initial IV bolus of heparin and then a continuous heparin IV infusion is usually started and continued for up to 10 days to prevent further enlargement of the thrombus and development of new thrombi; it has no effect on the existing clot, which the body dissolves over time. Daily heparin antifactor Xa or partial thromboplastin times (PTTs) are monitored to maintain therapeutic heparin levels. Warfarin is begun 4 to 5 days before the heparin is stopped because it requires 3 to 5 days to reach a therapeutic level. To monitor warfarin’s effects, INRs and PTs are done daily, and adjustments in warfarin doses are made based on the results. When the therapeutic INR goal is reached, the heparin is stopped. Warfarin is continued for several months, which necessitates regular monitoring of INR levels to ensure the drug’s level is within therapeutic range. For second DVT episodes, lifelong warfarin therapy is used.

An endovascular procedure using the Trellis™ peripheral infusion system is used to remove new-onset proximal (high in leg) blood clots within 2 weeks of symptom onset. A catheter with two balloons is inserted into the vein and through the clot. The balloons are inflated. Then a thrombolytic medication is instilled into the clot through holes along the catheter between the two balloons. The balloons prevent the medication from being systemically absorbed and keep the clot material contained as it dissolves. A motor oscillates (moves) the catheter to disperse the medication along the clot to help dissolve it. Any clot material that remains is aspirated out of the vein through the catheter. Patients usually go home in 24 hours and return to normal activity as ordered. To see this procedure, visit www.bacchusvascular.com/products/trellis/animation.html. Early removal of the clot with this combined mechanical and pharmacological approach improves quality of life and reduces post-thrombotic syndrome (PPS), which occurs in up to 50% of DVT patients within 1 year. PPS occurs after a DVT from damage to the vein valves and results in pain, swelling, and leg ulcers, which reduce quality of life. Little can be done for PPS, and treatment aims to prevent leg ulcers.

Other approaches are surgical treatment to prevent pulmonary emboli or chronic venous insufficiency when anticoagulant therapy cannot be used or the risk of pulmonary embolism is great. Venous thrombectomy removes the clot through a venous incision. In some cases, a vena cava filter is placed into the vena cava through the femoral or right internal jugular vein (Fig. 23.11). Once in place, it is opened and attaches to the vein wall. The filter traps clots traveling toward the lungs without hindering blood flow.

Nursing Process for the Patient With Thrombophlebitis

DATA COLLECTION. A patient history is obtained that includes questions regarding recent IV therapy or use of contrast

![Image](https://www.bacchusvascular.com/products/trellis/animation.html)
media, surgery, extremity trauma, childbirth, bed rest, recent long trips, cardiac disease, recent infections, and current medications that can put the patient at high risk of thrombus. Physical assessment is done noting pain, fever, tenderness, positive Homans’ sign, redness, warmth, swelling, edema, and a firm, cordlike vein in the affected extremity. Daily measurements are taken of bilateral thighs and calves and recorded to monitor swelling. Coagulation tests are monitored. Signs of a pulmonary embolism, such as dyspnea, tachycardia, tachypnea, blood-tinged sputum, chest pain, or changes in level of consciousness are immediately reported to the HCP.

**NURSING DIAGNOSES, PLANNING, INTERVENTIONS, AND EVALUATION.** See “Nursing Care Plan for the Patient With Thrombophlebitis” for specific nursing interventions. Teaching the patient about the disease and treatment is important to reduce anxiety about complications and to enhance adherence to treatment to prevent complications (see Box 23-4).

---

**Box 23-4 Patient Education**

**Anticoagulant Therapy**

Anticoagulants prolong the time it takes blood to clot, so it is important to prevent injury and to recognize and report signs of bleeding to the HCP.

**To Prevent Injury**

- Wear shoes or slippers; avoid going barefoot.
- Use an electric razor to shave.
- Use a soft toothbrush.

**Signs of Bleeding to Report to Physician**

- Easy bruising
- Nosebleeds
- Bleeding that does not stop
- Blood in urine
- Blood in sputum
- Blood in stools or black stools

**Additional Instructions**

- Avoid use of aspirin/NSAIDs because they further prolong the time it takes for a clot to form.
- Have lab work done as prescribed by HCP to monitor clotting time and medication dosage.

---

**Home Health Hints**

- On admission, measure the patient’s midcalf area so you have a baseline size. Reassess measurements during each visit. Subtle changes in measurement can indicate a potential problem.
- Note whether pressure is being applied on the popliteal area or calf muscle when a patient with venous circulation problems is sitting in a recliner with the leg rest up. The angle of the recliner and the patient’s height affect the position of the pressure. A small, flat pillow is placed underneath the knees and lower legs to open the angle and relieve the pressure.
- Report any abnormal findings following cardiovascular surgeries because patients are at a high risk for thrombophlebitis. They also are at risk for incisional infection, pneumonia, and pulmonary emboli.
- Encourage the patient to move often because immobility can contribute to thrombophlebitis.
- If the patient is bed bound, instruct both the patient and caregiver on simple active and passive ROM exercises. If necessary, consider involving occupational and physical therapists. Working collaboratively with therapy, an appropriate activity program can be planned.
- Assist patients to develop energy-conserving techniques by being observant of their lifestyles. For instance, notice the room and chair in which the patient spends most of the day. Trays and baskets can be used to hold items the patient may need or want, such as water, cup, medicines, tissues, a phone book, telephone, snacks, TV remote, reading material, paper, and pen. Other techniques to conserve energy are putting a carrying pouch on the front bar of a walker to carry items such as a portable phone or tissues and, if the house has stairs, putting a chair at the top and bottom of the stairs so the patient can rest.
- The caregiver should be the one to answer the door. When the patient is alone, a note can be placed on the door with instructions; however, the instructions should not convey that the patient is alone.
- Patients on oral anticoagulants should be instructed on dietary guidelines, adherence to follow-up labs, and potential complications. Many times, these patients are discharged with a booklet outlining his or her new medication. Spend time to review this information with the patient and family.
### NURSING CARE PLAN for the Patient With Thrombophlebitis

**Nursing Diagnosis:** Acute Pain related to inflammation of vein

**Expected Outcome:** The patient will report satisfactory pain relief within 30 minutes of pain report.

**Evaluation of Outcome:** Does patient report satisfactory pain relief?

**Intervention** Assess pain using rating scale such as 0 to 10. **Rationale** Self-report is the most reliable indicator of pain. **Evaluation** Does patient report pain using scale?

**Intervention** Provide analgesics and NSAIDs as ordered. **Rationale** Pain is reduced when inflammation is decreased. **Evaluation** Is patient’s rating of pain lower after medication?

**Intervention** Apply warm, moist soaks. **Rationale** Heat relieves pain and vasodilates, which increases circulation to aid comfort. Moist heat penetrates more deeply. **Evaluation** Does patient report increased comfort with warm, moist soaks?

**Intervention** Maintain bedrest with leg elevation above heart level. **Rationale** Elevation above heart level decreases swelling by aiding venous blood flow back to the heart. **Evaluation** Is swelling reduced, documented by measuring extremities?

**Nursing Diagnosis:** Impaired Skin Integrity related to venous stasis

**Expected Outcome:** The patient’s skin will remain intact.

**Evaluation of Outcome:** Does patient’s skin remain intact?

**Intervention** Observe skin for edema, skin color changes, and ulcers. Measure extremities, bilaterally at same location in each extremity. **Rationale** Monitoring will detect signs of skin integrity impairment and extremity swelling. Edematous skin breaks down more easily. **Evaluation** Are skin changes seen? Do daily measurements show a change in swelling?

**Intervention** Elevate feet above heart level. **Rationale** Elevation decreases swelling by increasing blood flow to heart. **Evaluation** Is swelling reduced?

**Intervention** Fit and apply elastic compression stockings after edema is reduced, as ordered. **Rationale** Elastic compression stockings are fitted after edema is reduced to avoid constriction. The compression of elastic stockings increases blood flow to reduce swelling. **Evaluation** Is swelling reduced?

**Intervention** Teach patient to avoid crossing legs or wearing constricting clothes. **Rationale** Crossing legs and constrictive clothes impair venous return. **Evaluation** Does patient state understanding of teaching?

---

### SUGGESTED ANSWERS TO CRITICAL THINKING

- **Mrs. Tepley**
  1. You might hear a murmur.
  2. Stress and caffeine increase the occurrence of palpitations.
  3. To help manage her condition, Mrs. Tepley needs a definition of MVP, stress management techniques, to know she should reduce caffeine intake (e.g., drink decaffeinated coffee), and to understand symptoms of endocarditis to report to her HCP.

- **Mrs. Pryor**
  1. In aortic stenosis, the valve is narrowed, which makes it more difficult for blood to leave the left ventricle and go into the aorta. This means there can be less
SUGGESTED ANSWERS TO

Mrs. Pryor is feeling tired.

Documentation using the SOAP method: S: “What is aortic stenosis?” O: Listened attentively during explanation that in aortic stenosis the valve is narrowed making it more difficult for blood to leave left ventricle to go to aorta. This means there can be less blood flow to the body. A: Interested in learning more about diagnosis. P: Provide more information written and verbal.

2. Angina results if the heart is not getting enough oxygen-rich blood.

3. Nursing care should include fall precautions due to syncope and fatigue. Teaching should be based on Mrs. Pryor’s need for safety at home, assistance with ADLs, and her questions and concerns.

4. Diagnoses and care include the following: Self-Care Deficits related to fatigue, so plan for meeting ADL needs. Activity Intolerance related to fatigue, so plan rest periods between activity and monitor vital signs with activity.

5. You should give two tablets. Here is an example of how to solve this problem using the unit analysis method:

\[
\frac{0.25 \text{ mg}}{1 \text{ tablet}} = \frac{0.125 \text{ mg}}{0.5 \text{ tablet}}
\]

SUGGESTED ANSWERS TO

Mrs. Jones
1. A heart murmur is heard from damaged heart valves.
2. Splinter hemorrhages appear as black or red lines in the nails.
3. Petechiae indicate that tiny pieces of a lesion on the endocardium or valves have broken off and become microemboli.
4. Subjective data collection findings might include patient statements such as, “I have pain in my joints and am chilled” or “I am fatigued and have no appetite.” Objective findings are as follows: temperature 100°F (37°C), red splinter hemorrhages in left index finger nailbed, many petechiae on chest.
5. Expected medications include IV antibiotics.
6. Chilling is muscular work that raises the body’s temperature. Raising the body’s temperature is part of the inflammatory process and is the body’s attempt at developing an unfavorable environment for the pathogen. Removing blankets to decrease fever results in chills and shivering, which further increases body temperature from the heat generated by muscular activity during shivering. Therefore, Mrs. Jones should be kept covered to prevent chills.
7. For left-sided HF, crackles, wheezes, cough, or dyspnea might be present. In right-sided HF, peripheral edema or jugular venous distention may be present.
8. Two tablets.

REVIEW QUESTIONS

1. The nurse is caring for a team of patients. After completing morning rounds, which of the following patients require priority care?
   1. A patient who is 2 days postsurgery reporting severe constipation.
   2. A patient with a DVT has peripheral edema.
   3. A patient with aortic stenosis who is reporting chest pain.
   4. A patient with mitral valve prolapsed has lost 2 pounds of weight this morning.

2. The nurse is evaluating patient teaching for mitral valve prolapse. The patient shows understanding of the prognosis of MVP by stating which of the following?
   1. “The prognosis is poor.”
   2. “There are often no symptoms.”
   3. “Heart failure often occurs.”
   4. “Symptoms quickly progress.”

3. The nurse is evaluating a patient’s preoperative teaching for a commissurotomy. The patient shows understanding of the purpose of this procedure by stating which of the following?
   1. “Fused valve flaps are separated to enlarge the valve opening.”
   2. “A mechanical valve is inserted to replace a valve.”
   3. “The valve flaps are repaired or reconstructed.”
   4. “A biological valve is inserted to replace a valve.”

4. The nurse is evaluating understanding after a teaching session for mechanical cardiac valve replacement surgery. Which statement by the patient indicates understanding of teaching?
   1. “You will need anticoagulants for the first month after surgery.”
   2. “You will not need to be on anticoagulant therapy.”
   3. “You will need anticoagulant therapy for the first year after valve replacement.”
   4. “You will need anticoagulant therapy for life.”
5. The nurse evaluates the patient as understanding how to prevent rheumatic fever if the patient states that rheumatic fever can be prevented by treating streptococcal infections with which of the following?
   1. Penicillin
   2. Prednisone
   3. Cortisone
   4. Cyclosporine

6. The nurse is caring for a patient with cardiomyopathy. Which of the following symptoms, if reported by the patient, require priority action by the nurse?
   1. Left great toe pain
   2. Dyspnea
   3. Headache
   4. Decreased appetite

7. The nurse is collecting data on a patient who had surgery. Which of the following signs and symptoms indicate to the nurse the possible presence of a deep venous thrombus in the patient’s leg? **Select all that apply.**
   1. Calf swelling
   2. Crackles
   3. Jugular venous distention
   4. Positive Homans’ sign
   5. Warmth
   6. Redness

8. The nurse reviews medication orders and is to give warfarin (Coumadin). Which of the following actions should the nurse take first?
   1. Obtain a glass of water.
   2. Prepare the medication for administration.
   3. Review international normalized ratio result.
   4. Document the medication administration.

LEARNING OUTCOMES

1. Explain the etiologies, signs, symptoms, and therapeutic measures of coronary artery disease, angina pectoris, and myocardial infarction.
2. List data to collect for patients with coronary artery disease, angina pectoris, or myocardial infarction.
3. Describe what therapeutic measures are used to treat coronary artery disease, angina pectoris, and myocardial infarction.
4. Explain the etiologies, signs, and symptoms for each of the peripheral vascular disorders.
5. Identify therapeutic measures used to treat peripheral vascular disorders.
6. Plan nursing care for patients with a peripheral vascular disorder.
Chapter 24  Nursing Care of Patients With Occlusive Cardiovascular Disorders  463

Cardiovascular diseases (CVDs) are the leading cause of disability and death in the United States. Diseases of the heart and peripheral vessels can affect quality of life and alter the ability of the individual to perform tasks of everyday living. Many factors leading to cardiovascular diseases can be controlled or modified. Education is important in preventing and treating occlusive CVDs.

An estimated 83.6 million American adults have one or more types of CVDs. In 2012, an estimated 785,000 Americans will have had a new myocardial infarction (MI) and 470,000 a recurrent MI. About every 25 seconds, a person in the United States will have a coronary event, and every minute someone will die from one (Roger et al, 2012).

More than one in three women have some form of CVD, which occurs on average about 6 years later than in men, often after menopause. In 2010, incidence of coronary heart disease (CHD) was greatest in people over age 65. The prevalence among men was 7.8% and in women, 4.6%. The average age for a person having a first heart attack is 64.5 for men and 70.3 for women. Smoking lowers this age for both genders but more so for women. Because women typically have heart attacks at older ages than men, they are more likely to die from heart attacks within a few weeks. It is interesting to note that the prevalence of CHD decreases with higher education. People with less than a high school education had rates of 9.2%, whereas those with a college degree had rates of 4.6% (Centers for Disease Control and Prevention, 2011).

ARTERIOSCLEROSIS

Arteriosclerosis is a disorder characterized by thickening, loss of elasticity, and calcification of arterial walls. This condition is part of the aging process in which the intimal lining of the artery wall loses elasticity and weakens. This weakening is due to the high pressure that carries blood within arteries.

ATHEROSCLEROSIS

Atherosclerosis is the formation of plaque within the arterial wall. Arteriosclerosis and atherosclerosis are conditions that may begin in early childhood and progress without symptoms through adult life. It causes coronary artery disease (CAD), leading to CHD (Table 24.1).

Pathophysiology

Atherosclerosis is a multistep process that affects the inner lining of the artery (Fig. 24.1). First injury to the endothelial cells that line the walls of the arteries occurs, causing inflammation and immune reactions. Damage to the endothelium stimulates the growth of smooth muscle cells. These cells secrete collagen and fibrous proteins. Lipids, platelets, and other clotting factors accumulate. Scar tissue replaces some of the arterial wall.

FIGURE 24.1 (Top) Cross-section of normal coronary artery. (Bottom) Coronary artery with atherosclerosis narrowing the lumen.

An early indication of injury is a fatty streak on the lining of the artery. This buildup of fatty deposits is known as plaque. It is composed of smooth muscle cells, fibrous proteins, and cholesterol-laden foam cells. Plaque has irregular, jagged edges that allow blood cells and other material to adhere to the wall of the artery. The portion of the plaque that faces the bloodstream develops a fibrous cap, a firm shell that often contains calcium. Over time this buildup becomes calcified and hardened, causing turbulence that damages cells...
and increases the buildup within the vessel. Sometimes the plaque’s fibrous cap tears or ruptures, and a blood clot forms. This blood clot can completely block the coronary artery, or it may break loose and lodge within a smaller artery leading to the heart. The vessel may also become stenosed (narrowed) by plaque buildup. This buildup of plaque may cause partial or total occlusion of the artery, resulting in reduced blood flow. The area distal to the occlusion may become ischemic as a result.

**Etiology**

Risk factors for atherosclerosis can be divided into two categories: those that can be modified and those that cannot (Table 24.2).

**Diagnostic Tests**

Total cholesterol levels above 200 mg/dL increase risk of MI (see Table 21.3). **Low-density lipoproteins** (LDLs) increase CAD risk, but **high-density lipoproteins** (HDLs) are protective against CAD. A risk factor for premature CAD is a high Lp(a) cholesterol (a genetic variation of plasma LDL) level. Apolipoprotein B particles in LDL-type cholesterol are able to infiltrate the arterial wall, rapidly causing damage. People with a higher proportion of apolipoprotein B to apolipoprotein A are at a much higher risk for CVD. **C-reactive protein** (CRP) can indicate low-grade inflammation in coronary vessels and long-term heart disease risk. Elevated blood glucose levels can increase the risk for atherosclerosis. Radiological studies of the arteries can be performed to show narrowed or occluded vessels (see Chapter 21).

**Therapeutic Measures**

A healthy lifestyle, controlling risk factors, medications, and medical exams are helpful in controlling arteriosclerosis and atherosclerosis.

**Diet**

Because the formation of plaque within arteries is primarily caused by fatty deposits, an adherence to a healthy diet is recommended by the AHA. Heart-healthy foods include a variety of those colorful fruits and vegetables that have no trans fat; are low in saturated fat, cholesterol, sodium, and added sugars; and those that are high in whole-grain fiber and lean protein (“Nutrition Notes”). The AHA has guidelines and diets for decreasing fat and cholesterol intake at http://mylifeccheck.heart.org.

**Smoking**

The risk of developing CAD is two to six times higher in cigarette smokers than in nonsmokers. Risk is proportionate to the number of cigarettes smoked. Smoking contributes to a

smoking and effects of exposure to secondhand and thirdhand (residual nicotine and other chemicals left on indoor surfaces—from skin, clothing, and hair to bedding, carpets, floors, furniture, and walls—by tobacco smoke) smoke should be presented to patients. The American Cancer Society has many programs to help patients quit smoking. Visit its website at www.cancer.org.

Exercise
Increased activity raises HDL levels. Increasing physical activity may also lower insulin resistance and facilitate weight loss. Over time, exercise also leads to the development of collateral circulation, which allows blood to flow around occluded sites. Before beginning an exercise program, consult a health care provider (HCP).

Medications
Lowering lipid levels is the primary therapy for atherosclerosis. When dietary control is not effective, medication is also used (Table 24.3). It may take 4 to 6 weeks before lipid levels respond to drug therapy. If one drug does not control lipids, another drug can be added.

CORONARY ARTERY DISEASE

Coronary artery disease is the obstruction of blood flow through the coronary arteries to the heart muscle cells, typically from atherosclerosis. Blood flow reduction resulting from CAD can cause angina, MI, or sudden death if blood flow is not restored.

Prevention
Risk factors for CAD are listed in Table 24.2. The risk factors that can be changed should be modified following the AHA’s guidelines (see therapeutic measures for atherosclerosis). Low-dose aspirin as recommended by an HCP can be used to prevent the formation of a thrombus.

Angina Pectoris

Pathophysiology
When an increased workload is placed on the heart, as in exercise or strenuous activity, there is an increased demand for oxygen. Normally, when the heart muscle needs more oxygen, the coronary arteries dilate to carry more blood and oxygen. However, with CAD, the narrowed vessels are unable to dilate and supply the heart muscle with this extra blood and oxygen. This inability to supply more blood and oxygen causes myocardial ischemia and can produce its symptom, angina pectoris (chest pain). Angina may also result from other conditions that cause myocardial ischemia such as vasospasm, valvular heart disease, hypertension, or heart failure (HF).

Nutrition Notes

Controlling Blood Cholesterol With Diet
Two-thirds of the body’s cholesterol is produced by the liver and intestines. Most people produce less cholesterol or increase its excretion in response to high levels of dietary cholesterol, but others respond weakly. In particular, obese individuals respond less to reductions in dietary saturated fat and cholesterol than do lean persons (Flock, Green, Kris-Etherton, 2011). Although only foods of animal origin contain cholesterol, some vegetable oil products contain trans fats, potent risk factors for cardiovascular disease.

The basis for the cholesterol-lowering diet is:
• Reducing saturated fat to less than 7% of total kilocalorie intake
• Reducing dietary cholesterol to less than 200 milligrams per day.

In dietary studies of about 1 month duration where all foods were provided, LDL cholesterol is reduced by 22 to 30%, whereas in community-based studies of more than 6 months’ duration, where dietary advice is the basis of the intervention, reduction in LDL cholesterol is about 15%. This amount is possibly sufficient to reduce the need for pharmaceutical interventions (Harland, 2012).

Specific strategies to lower blood cholesterol include the following:
• Reducing saturated fat intake by choosing
  • 2 to 3 servings per day of nonfat or low-fat dairy products
  • 5 ounces of lean meat per day, trimming fat from meat, rinsing browned ground beef, and skimming fat from meat juices for soup or gravy
  • 2 egg yolks per week; egg whites, egg substitutes as desired

Adding foods for which the U.S. Food and Drug Administration has approved health claims such as:
• Foods rich in marine omega-3 fatty acids (herring, mackerel, rainbow trout, salmon, sardines, swordfish, and tuna)
• Foods containing soluble fiber (Kellogg’s Bran Buds, barley, oatmeal)
• Soy-containing foods
• Foods containing plant sterols (butter and margarine spreads, juices, salad dressings, soy milk) that interfere with intestinal absorption of cholesterol. Note, however, that they are contraindicated in a rare autosomal recessive disorder called sitosterolemia.

loss of HDL. These proteins are the best cholesterol to have in the body to decrease the risk of CVDs. Smoking also causes vasoconstriction, which leads to angina pectoris and cardiac dysrhythmias. The benefits of smoking cessation are dramatic and almost immediate. Education about the risks of smoking and effects of exposure to secondhand and thirdhand (residual nicotine and other chemicals left on indoor surfaces—from skin, clothing, and hair to bedding, carpets, floors, furniture, and walls—by tobacco smoke) should be presented to patients. The American Cancer Society has many programs to help patients quit smoking. Visit its website at www.cancer.org.

Exercise
Increased activity raises HDL levels. Increasing physical activity may also lower insulin resistance and facilitate weight loss. Over time, exercise also leads to the development of collateral circulation, which allows blood to flow around occluded sites. Before beginning an exercise program, consult a health care provider (HCP).

Medications
Lowering lipid levels is the primary therapy for atherosclerosis. When dietary control is not effective, medication is also used (Table 24.3). It may take 4 to 6 weeks before lipid levels respond to drug therapy. If one drug does not control lipids, another drug can be added.

CORONARY ARTERY DISEASE

Coronary artery disease is the obstruction of blood flow through the coronary arteries to the heart muscle cells, typically from atherosclerosis. Blood flow reduction resulting from CAD can cause angina, MI, or sudden death if blood flow is not restored.

Prevention
Risk factors for CAD are listed in Table 24.2. The risk factors that can be changed should be modified following the AHA’s guidelines (see therapeutic measures for atherosclerosis). Low-dose aspirin as recommended by an HCP can be used to prevent the formation of a thrombus.

Angina Pectoris

Pathophysiology
When an increased workload is placed on the heart, as in exercise or strenuous activity, there is an increased demand for oxygen. Normally, when the heart muscle needs more oxygen, the coronary arteries dilate to carry more blood and oxygen. However, with CAD, the narrowed vessels are unable to dilate and supply the heart muscle with this extra blood and oxygen. This inability to supply more blood and oxygen causes myocardial ischemia and can produce its symptom, angina pectoris (chest pain). Angina may also result from other conditions that cause myocardial ischemia such as vasospasm, valvular heart disease, hypertension, or heart failure (HF).

• WORD • BUILDING •

angina pectoris: angina—to choke + pectora—chest
The pain has a longer duration than stable angina, can occur with exercise or at rest, and often occurs at night.

**Signs and Symptoms**

Anginal pain manifests in several ways. Patients (especially men) often describe the pain as heaviness, tightness, squeezing, viselike, or crushing in the center of the chest or adjacent to the chest (Fig. 24.2). The pain can radiate down one or both arms, with pain in the left arm being more common, into the shoulder, neck, jaw, or back. Patients may also describe heaviness in their arms or a feeling of impending doom. During the episode of pain, the patient may be pale, diaphoretic, or dyspneic. The pain is usually brought on by exertion and subsides with rest. It can be relieved with a vasodilator such as NTG. Episodes of chest pain may increase in frequency and severity over time. If patients do not heed the warning to stop their activity and rest, they may be at risk for MI or sudden death.

### Types of Angina

Angina can be classified as stable (less serious) or unstable.

**Stable Angina.** Stable angina is chest pain that occurs with moderate exertion in a pattern that is familiar to the patient. The pain is predictable and can usually be managed with nitroglycerin (NTG) and rest. The pain of stable angina usually subsides when the activity is stopped.

**Ventricular or Vasospastic Angina (Prinzmetal’s Angina).** This type of angina is caused by coronary artery spasms and is serious. The pattern of occurrence is often cyclical, with the pain presenting about the same time each day. The pain has a longer duration than stable angina, can occur with exercise or at rest, and often occurs at night.

**LEARNING TIP**

Angina pectoris is not a disease. It is the symptom of ischemia that results from a lack of oxygen and blood flow to the heart muscle.
Any event that increases oxygen demand can cause an anginal attack. Most often, precipitating events include large meals, exercise, cold, stimulant drugs such as cocaine or amphetamines, stress, and emotional tension. Angina commonly occurs in the morning between 0600 and 1200 when the patient arises and the workload of the heart increases.

Women often experience angina symptoms atypically. They can experience chest pain, jaw pain, or heartburn but often have atypical symptoms of shortness of breath, fatigue, nausea, or less severe pain. Atypical symptoms should be recognized as possibly being cardiac related so that they are not ignored and treatment is sought. (See the “Women and Heart Health” section.)

**Diagnostic Tests**

Common tests for diagnosing CAD or angina causes include electrocardiogram (ECG), exercise stress test, echocardiography, chemical stress testing, cardiac computed tomography (CT) scan, cardiac magnetic resonance imaging (MRI)/magnetic resonance angiogram (MRA), radioisotope imaging, and coronary angiography (see Table 21.3).

**Therapeutic Measures**

Treatment for CAD and angina is directed at relieving and preventing anginal episodes that could lead to a MI. The risk factors identified for the patient determine the course of treatment. Weight reduction following a heart healthy diet and stress reduction may help slow disease progression. The three major groups of medication used for relieving angina are vasodilators (nitrates), calcium channel blockers, and beta blockers (Table 24.4).

**VASODILATORS.** NTG, a nitrate, is the drug of choice for acute anginal attacks. Nitrates dilate coronary arteries to increase oxygen to the myocardium and dilate peripheral

</tbody>
</table>
vessels so the heart does not have to work so hard to pump blood into them. NTG can be administered sublingually, orally, transdermally, intravenously (IV), or as a lingual spray. When administered sublingually, NTG may relieve chest pain within 1 to 2 minutes (Box 24-1).

**BE SAFE!**

Sublingual NTG:
AHA guidelines instruct people to immediately call 911 after one tablet and 5 minutes if pain remains unrelieved and symptoms of a MI are occurring.

Transdermal NTG:
Wear gloves to protect yourself from hypotension from touching the ointment or patch medication. Always remove the previous ointment or patch before applying a new one to prevent overdose.

Long-acting nitrates are used to prevent chest pain rather than to treat acute pain. They can be given orally, in ointment, or by transdermal patches. A problem with long-acting nitrates is the development of a tolerance to the drug. To prevent tolerance, the patch or ointment is usually removed at bedtime and reapplied in the morning, giving the patient an 8- to 12-hour nitrate-free period. Headaches may be experienced when nitrates are first begun. This side effect usually subsides after a week or two and can be relieved with aspirin.

**CALCIUM CHANNEL BLOCKERS.** Calcium is required for electrical excitability of cardiac cells and contraction of the myocardium and vascular smooth muscle. Calcium channel blockers relax vascular smooth muscle, which leads to decreased peripheral vascular resistance (afterload) and decreased myocardial oxygen demand. These drugs dilate main coronary arteries, increasing the myocardial oxygen supply. Calcium channel blockers are also used to decrease systolic and diastolic blood pressures and to slow the heart rate. Because these drugs are slow acting, they are ineffective in relieving acute anginal attacks. Side effects of calcium channel blockers are usually mild and include constipation, fluid retention, headache, and dizziness.

**Box 24-1 Key Points for Using Sublingual Nitroglycerin**

- Carry nitroglycerin (NTG) tablets at all times.
- Keep NTG tablets tightly sealed in the original container and protected from heat, light, and moisture.
- Replace NTG prescription at least every 6 months for maximum effect or every 3 to 4 months if carried in a pocket next to body heat.
- Take NTG tablet before an activity known to cause chest pain.
- Sit or lie down when taking NTG tablets, if possible.
- Take one NTG tablet. If the symptoms are not worsening but not completely relieved, your HCP may tell you to repeat a tablet every 5 minutes up to a total of three tablets. If pain is not relieved after three tablets, call 911.
- If pain is unrelieved after one NTG tablet and other symptoms of myocardial infarction are present, call 911 for emergency medical care.
- Tingling should be felt under the tongue when NTG tablets are used.
- NTG may cause a headache initially. Aspirin may relieve it.
- NTG may cause lightheadedness. Rise slowly to prevent falls.

**BE SAFE!**

Those who take nitrates should not use drugs such as sildenafil (Viagra), tadalafil (Cialis), or vardenafil (Levitra) for erectile dysfunction because these types of drugs dilate blood vessels and may cause a significant drop in blood pressure if used together.

**BETA BLOCKERS.** Beta blockers decrease heart rate, lower blood pressure, and prevent release of renin. This results in decreased workload on the heart to help prevent anginal attacks. Because of these decreased effects, beta blockers should be used with caution in patients with any degree of HF because it may make HF worse. There are nonselective and selective types of beta-adrenergic blockers. People with asthma or chronic obstructive pulmonary disease (COPD, including emphysema, bronchitis, and bronchiectasis) should avoid nonselective beta-adrenergic blockers because they cause bronchoconstriction. Metoprolol (Lopressor) and atenolol (Tenormin) are cardioselective and can be used in patients with asthma and COPD. Beta blockers are not effective for coronary artery spasms and should not be used for variant (Prinzmetal’s) angina.

**LEARNING TIP**

To help you identify beta blockers, remember that their generic names end with -olol.

**ANGIOTENSIN-CONVERTING ENZYME INHIBITORS.** Angiotensin-converting enzyme (ACE) inhibitors block production of angiotensin II, which is a potent vasoconstrictor. This action reduces peripheral arterial resistance (vasodilation), which
lowers blood pressure. ACE inhibitors may cause retention of potassium in some patients. If a patient taking an ACE inhibitor develops a dry cough, inform the HCP so the medication can be changed.

**STATINS.** Cholesterol and inflammation in artery walls are involved in atherosclerosis development. Statins lower cholesterol levels by reducing cholesterol production in the liver (see Table 24.3). They also reduce inflammation and CRP levels, which improves patient outcomes in CAD. Statins are used to prevent and treat atherosclerosis and the disorders caused by it.

**ANTIPLATELETS.** Aspirin and clopidogrel (Plavix) are commonly used antiplatelets that help prevent cardiovascular events.

**Nursing Process for the Patient With Atherosclerosis, Coronary Artery Disease, and Angina**

### Data Collection

A health history is obtained regarding the patient’s nonmodifiable and modifiable risk for atherosclerosis and CAD. A history of chest pain, fatigue, or activity intolerance is noted. Allergies and current medications, including over-the-counter and prescription drugs are documented. Height, weight, and diet history are recorded.

Assess anginal pain by patient’s description of pain: type, location, and pain radiation to other areas of the body. Note skin color and temperature. Note any factors that may make the pain worse or better. This will provide information to determine improvement or lack of improvement in pain. Ask how long the patient has had angina, triggering activities, and how the pain has been relieved in the past. Note the presence of dyspnea, labored respirations, diaphoresis, or nausea. Obtain vital signs, blood pressure, apical pulse, respiration, and oxygen saturation to provide a baseline of the patient status.

**Nursing Diagnoses, Planning, and Implementation**

**Acute Pain related to reduced coronary artery blood flow and increased myocardial oxygen needs causing an imbalance between oxygen supply and demand**

**EXPECTED OUTCOME:** The patient will report an absence of pain.

- Ensure vascular access is established. *IV access may be necessary to use to administer drugs for pain relief.*
- Administer oxygen as ordered via nasal cannula to increase oxygen availability to myocardium.
- Obtain a 12-lead ECG as ordered to determine ischemia or injury of the myocardium with evaluation of the ST segment.
- Administer aspirin as prescribed to decrease platelet aggregation.
- Administer morphine as prescribed to provide pain relief.
- Administer nitroglycerin (sublingual, spray) as ordered. Notify HCP if pain is unrelieved after three doses of NTG or as prescribed, or if vital signs change. Chest pain unrelieved by nitrates may represent unstable angina or MI.
- Remain with patient and reassess pain in 5 minutes after administration of medication. *A patient who has chest pain should never be left alone.*
- Notify HCP of ECG changes. ST-segment elevation may indicate a MI (see Chapter 25).
- Offer the patient assurance and emotional support to decrease anxiety. Emotional support is important because patients and their families are often afraid that the patient may die.
- Promote rest and decrease anxiety for the patient with chest pain to help relieve stress and chest pain.
- Document patient data in the medical record to communicate patient’s problem and outcome.

**Deficient Knowledge related to ineffective management of regimen for atherosclerosis or coronary artery disease**

**EXPECTED OUTCOME:** The patient will report understanding and management of atherosclerosis and CAD.

- Identify cognitive or physical impairments that would interfere with the patient’s ability to learn desired information.
- Include significant other as appropriate to support patient during learning.
- Collect data on patient’s present understanding of atherosclerosis and CAD to determine baseline knowledge.
- Collect data on patient’s readiness to learn and desired learning needs and feelings about incorporating lifestyle changes into daily routine to prioritize teaching topics.
- Determine cultural beliefs because they may influence learning.
- Provide for patient’s physical comfort during teaching to increase learning.
- Use appropriate teaching tools to meet individual learning needs, such as pamphlets, diagrams, or other written materials in simple language.
- Use an interpreter as needed and provide written materials in patient’s native language to facilitate understanding.
- Explain pathophysiology of atherosclerosis and CAD, control of risk factors, and management of CAD symptoms to promote understanding.
- Explain action, side effects, and importance of taking medications as prescribed to relieve pain and prevent complications.
- Provide information about community resources that can assist in making lifestyle changes, such as weight loss, smoking cessation, stress management, and exercise.
- Teach patient to monitor blood pressure and heart rate as appropriate and to report chest pain or dyspnea, which may point to the presence of complications from CAD.
- Help patient plan how to incorporate information into daily life to increase likelihood that change will occur.
- Encourage questions and allow patient opportunity to verbalize new information and skills to enhance learning.
- Document teaching and evaluation of patient knowledge to validate understanding.

**Evaluation**

Interventions are successful if the patient is pain free and has an increased understanding of atherosclerosis and CAD and their management and states that he or she will modify risk factors of CAD.
The term **acute coronary syndrome** (ACS) is used to encompass the continuum of CAD such as unstable angina pectoris and MI. Acute coronary syndrome is caused by a sequence of inflammatory processes mediated by activated macrophages, plaque rupture, tissue factor expressions and platelet activation leading to thrombus formation and coronary vessel occlusion.

**Unstable Angina**

Unstable angina occurs in patients with worsening CAD and is noted by its changing or unpredictable pattern. Rest does not decrease the chest pain of unstable angina. This pain may even occur when the patient is at rest. The episodes of chest pain with unstable angina increase in frequency and severity, placing the patient at risk for myocardial damage or sudden death. Symptoms of angina usually occur when an artery is narrowed by at least 60% to 70%.

**Myocardial Infarction**

An MI (heart attack), results in the death of heart muscle. The affected myocardial cells in the heart are permanently destroyed. An MI occurs from a partial or complete blockage of a coronary artery, which decreases the blood supply to the cells of the heart supplied by the blocked coronary artery. The extent of the cardiac damage varies depending on the location and amount of blockage in the coronary artery. This is a potentially devastating condition. The ability of the heart to contract, relax, and propel blood throughout the body requires healthy cardiac muscle. Results depend on the speed and effectiveness of treatment.

MI is identified by type. Non–ST -segment elevation MI (NSTEMI) is also known as a non–Q-wave MI. An ST-segment elevation MI (STEMI) is also known as a Q-wave MI and is the deadliest type because it is usually caused by a complete blockage of the artery. (See Chapter 25 for ST-segment definition.) With timely reperfusion, cell death may not occur, which reduces the amount of permanent damage.

Those experiencing an MI are typically men over age 40 with atherosclerosis. Although MIs can occur at any age in men or women, women who smoke and use oral contraceptives have a higher risk.

**Silent Ischemia**

Silent ischemia occurs without pain and can carry great risk. The older adult and those with hypertension or diabetes most often have silent ischemia.

**Sudden Cardiac Death**

Sudden cardiac death is cardiac arrest triggered by lethal ventricular dysrhythmias or asystole from an abrupt occlusion of a coronary artery (see Chapter 25). Prompt treatment is required in an attempt to prevent death.

**Pathophysiology**

MI does not happen immediately. Ischemic injury evolves over several hours before complete necrosis and infarction take place. The ischemic process affects the subendocardial layer, which is most sensitive to hypoxia. This process leads to decreased myocardial contractility. The body’s attempt to compensate for decreased cardiac function triggers the sympathetic nervous system to increase the heart rate. The change in heart rate increases myocardial oxygen demand, further depressing the myocardium.

Prolonged ischemia can produce severe cellular damage and necrosis of cardiac muscle. Once necrosis takes place, the contractile function of the muscle is permanently lost. The heart has a zone of ischemia and injury around the necrotic area (Fig. 24.3). The zone of injury is next to the necrotic area and is susceptible to becoming necrosed. If treatment is initiated within the first hour of symptoms of the MI, the area of damage can be minimized. Around the injury zone is an area of ischemia and viable tissue. If the heart responds to treatment, this area can rebuild and maintain collateral circulation. If prolonged ischemia takes place, the size of the infarction can be quite large. The size of the infarction depends on how quickly the blood supply from the blocked artery can be restored.

The area affected by an MI depends on the coronary artery involved and the extent of occlusive coronary disease (Fig. 24.4). Being familiar with the anatomy of the heart and the area of the MI helps the nurse anticipate dysrhythmias, conduction disturbances, and HF, which are the major complications of MIs (Table 24.5).
An occlusion of the RCA leads to an inferior MI and abnormalities in impulse formation and conduction. Serious dysrhythmias can occur early in an inferior MI that may be life threatening.

The left circumflex coronary artery feeds the lateral wall of the heart and part of the posterior wall of the heart. A lesion in the circumflex leads to a lateral wall infarction of the left ventricle.

The left coronary artery feeds the anterior wall of the heart, which also includes most of the left ventricle. An occlusion in this area causes an anterior wall MI. When the left ventricle is affected, there can be severe loss of left ventricular function, leading to severe changes in the hemodynamic status of the patient.

The right coronary artery (RCA) feeds the inferior wall of the heart and parts of the atrioventricular node and the sinoatrial node.

### LEARNING TIP

To remember which coronary artery occlusion results in a specific MI location, use coast-to-coast U.S. location initials such as those given below. You can personalize the locations with initials of landmarks familiar to you:

<table>

Signs and Symptoms

Chest pain is a classic symptom of an MI. The pain begins suddenly and continues without relief with rest or administration of NTG. The pain in the center of the chest is usually described as crushing, viselike, or as if an elephant is standing on the chest. The pain may radiate to the back, one or both arms and shoulders, neck, or jaw. The pain can imitate indigestion or a gallbladder attack with abdominal pain and vomiting. Other classic MI symptoms include shortness of breath, dizziness, nausea, and sweating (Table 24.6). When listening to lung sounds, crackles or wheezing may be heard. The pulse may be rapid or irregular, and an extra heart sound (referred to as S₃ or S₄) may be present. The presence of an extra heart sound can mean ventricular failure is imminent.

TIMELY SYMPTOM TREATMENT. Individuals often deny or fail to recognize that an MI is occurring because they experience atypical MI symptoms or their symptoms are similar to other mild conditions such as indigestion (“Gerontological Issues”). Patients have reported that the symptoms of an MI that they experienced were not what they expected. If people expect to have the dramatic heart attack symptoms seen on television (which are usually not the same as those in real life) and they do not, they are likely to wait to seek treatment. Waiting 2 to 24 hours before seeking medical care is common, yet the first hour after symptom onset is crucial for administering the newer reperfusion treatments that restore blood flow, minimize tissue damage, and save lives. Individuals should not drive themselves or let someone else drive them to the hospital if they are having chest pain. Call emergency medical care (911 or local emergency services number) so lifesaving treatment can begin.

Because so few people arrive at the emergency room quickly enough to benefit from reperfusion treatment, several agencies have educational programs to address this issue. Individuals need to be educated that “time is muscle.” As time passes during an MI, more muscle is lost. The National Heart, Lung, and Blood Institute and the AHA promote a campaign called “Act in Time to Heart Attack Signs.” The purpose of the campaign is to educate people on the importance of recognizing heart attack symptoms, working with a HCP to create a heart attack survival plan, and calling 911 as soon as symptoms begin. For more information, visit:

www.nhlbi.nih.gov/health/health-topics/topics/heartattack

Women and Heart Health

Heart disease remains the leading cause of death in women in the United States. American women are six times more likely to die of heart disease than breast cancer. Heart disease kills more women than all cancers combined in the 65-year-old group. Ethnicity is also a factor among women. African American women are more likely than Caucasian women to develop heart disease. Women tend to have an acute MI at an older age than men. Women also have a higher mortality rate when compared to men with acute MI.

Gerontological Issues

With age, the heart has decreased elasticity and decreased ability to respond to changes in pressure. This increases resistance to its pumping action and increases the workload of the myocardium.

Symptoms:

- Older patients should be taught never to neglect symptoms of shortness of breath, fatigue, fast or slow heartbeats, or chest discomfort.
- MIs that can occur without the presence of pain, a silent MI, most often occur in the older adult or those with diabetes regardless of age.
- When pain is not present, the only symptom may be a sudden onset of shortness of breath or fainting, restlessness, or a fall.
- Atypical presentation of MI symptoms is normal in older people, especially those older than age 85. Because the older adult has had more time to develop collateral circulation than younger people, they often do not have as many complications with an MI.

Therapies:

- In the older adult, reperfusion therapies such as angioplasty and bypass surgery seem to be superior in improving quality of life without increasing mortality risk. Statin therapy has also been shown to reduce mortality in those over age 80.

Continued
and are more likely to have complications such as ventricular fibrillation and HF than men.

Women may have classic chest pain, but they are also likely to have other symptoms as well that men do not typically have. Research is focusing on understanding women and cardiac disease. Atypical symptoms reported by women may include extreme fatigue, epigastric pain, jaw pain, indigestion, nausea and vomiting, dyspnea, shortness of breath, or cramping in the chest. A high percentage of women (more than 50%) noted prodromal symptoms a month before an acute MI. These symptoms included unusual fatigue, sleep disturbances, and shortness of breath. Fewer than 30% reported chest discomfort.

Delay in seeking care has also been identified in women. Women also often do not associate their symptoms with a heart attack because they believe it is a male condition. Women with atypical symptoms usually delay treatment, and when treated have less aggressive management, which leads to increased mortality.

**Diagnostic Tests**

Patients with a strong familial history of MI should be considered at risk until an MI is ruled out. Indicators of an MI are patient history, ECG, and serum cardiac troponin I or T, myoglobin, and CK-MB levels (see Chapter 21). C-reactive protein levels are elevated in the presence of inflammation. Magnesium levels are also checked, especially for those on diuretic therapy. Before thrombolytic or heparin therapy, international normalized ratio (INR) and partial thromboplastin time (PTT) are determined. The ECG usually shows the area that has infarcted, as well as the ischemic areas of the heart. Myocardial damage can be seen as ST-segment elevation, the presence of a Q-wave, or T-wave abnormalities (Fig. 24.5). Serial ECGs are done to monitor changes indicating damage or ischemia.

**FIGURE 24.5** Electrocardiogram changes during myocardial infarction. (A) Injury: ST-segment elevation. (B) Ischemia: ST-segment inversion. (C) Necrosis: large Q-wave and ST-segment elevation.
**Therapeutic Measures**

Treatment should be sought within 5 minutes for any unrelied chest pain. The AHA recommends chewing one uncoated adult aspirin at the onset of chest pain as directed by an HCP. Delays in seeking care can limit treatment options and result in more cardiac damage (Box 24-2).

Time until intervention is directly related to mortality. Guidelines now consider first medical contact to intervention rather than “door-to-needle” time. The goal is to restore blood flow to the heart muscle within 90 minutes or less of the patient’s arrival at the emergency department. Percutaneous coronary intervention should be initiated within 90 minutes. A reperfusion drug, when used, should be given within 30 minutes of the patient arriving at the emergency department (Barto, 2013).

The presence of chest pain indicates a lack of oxygen to the myocardium. Patients reporting chest pain are treated as if they have an MI until proven otherwise through testing.

**Oxygen.** Oxygen is administered immediately, usually at 2 L/min via nasal cannula. Oxygen therapy may be limited to the first 6 hours in stable patients. Too much oxygen can lead to systemic vasoconstriction, which may increase myocardial workload. Arterial blood gases (ABGs) are drawn to determine the patient’s oxygen needs. Oxygen saturation should be monitored and kept above 94%. Oxygen can be administered via mask if higher concentrations are needed. Mechanical ventilation can be provided when indicated by ABGs.

**Percutaneous Coronary Intervention.** Percutaneous coronary intervention (PCI) is a mechanical procedure to increase blood flow and oxygen to the myocardium. Emergency PCI is being used frequently in the management of acute MI, with improved outcomes for patients.

**Balloon Angioplasty.** In a cardiac catheterization laboratory, a catheter with a balloon tip is inserted, usually via the femoral artery, and advanced into the heart to open the blocked coronary artery (Fig. 24.6). Once the blocked artery is entered, the balloon on the catheter is inflated and the atherosclerotic plaque is compressed. The dilated vessel is able to deliver more oxygen-rich blood to the myocardium. Angioplasty can be done with or without the placement of stents.

**Coronary Artery Stent.** A coronary artery stent, placed during angioplasty, is used to prevent closure of a coronary artery from an atherosclerotic lesion. A stent is an expandable metal mesh tube that is implanted at the site of blockage in the coronary artery (Fig. 24.7). A stent provides support to a coronary artery wall at the area of stenosis to keep blood flowing through the artery. Complications associated with stent placement include thrombosis (formation of a blood clot inside a blood vessel).

---

**Box 24-2 Preventing Delays in Myocardial Infarction Treatment**

- Understand symptoms and the “time is muscle” principle.
- Develop an action plan and rehearse it.
- Understand normal emotional responses of anxiety, denial, or embarrassment.
- Educate family to follow action plan.
- Establish protocols in workplaces for employees experiencing myocardial infarction.
- Establish emergency room policies that reduce delays, such as having equipment and medication readily available.
bleeding from anticoagulation, stent occlusion, or coronary artery dissection. Drug-eluting stents are coated with immunosuppressant medication that can be released at the implantation site to reduce the risk of restenosis. The medication is released over months to inhibit smooth muscle cell proliferation to reduce risk of restenosis. Antiplatelet medications are recommended after stent placement to help prevent clot formation.

**MEDICATION.** For those with unstable angina, taking antiplatelets, statins, ACE inhibitors, and beta blockers is beneficial. A drug from each of these drug classes should be considered. When taken together, these drugs have a synergistic effect in fighting plaque, which means the y have a greater positive result for the patient. Research has shown that not all eligible patients are prescribed each of these medications. Patient teaching can include the need to ask the HCP about these drug classes to ensure they receive the ones for which they are eligible.

Table 24.7 summarizes pharmacological treatment of MI. MONA is a mnemonic in the Advance Cardiac Life Support guidelines for remembering the medications to give in treating a suspected MI: morphine, oxygen, nitroglycerin, and aspirin.

ANALGESICS. Analgesics are given for relief of chest pain. Morphine sulfate is the most commonly used narcotic. It is usually given in increments of 2 to 8 mg IV every 5 to 15 minutes until pain is relieved. The patients should be monitored for hypotension, respiratory depression, oversedation, and morphine sensitivity. In addition to pain relief, morphine helps decrease anxiety, opens bronchioles, and increases peripheral blood pooling to decrease preload (blood returning to heart) and afterload (pressure within the aorta), which can help increase blood supply and oxygen to the myocardium.

VASODILATORS. NTG sublingually, topically, or by IV drip can be administered for vasodilation to supply more blood to the myocardium to reduce pain and the workload of the heart. In the acute phase, the IV route is usually used. Nitrates should not be given if the patient has a systolic blood pressure of less than 90 mm Hg or 30 mm Hg or more below baseline, severe bradycardia less than 50 beats per minute, or if the patient has taken a phosphodiesterase inhibitor for erectile dysfunction. Catastrophic hypotension may result.

THROMBOLYTICS. Thrombolytic therapy is used to dissolve a blood clot that is occluding a coronary artery. Thrombolytic therapy must be started within a specified time range from the onset of symptoms, usually within 1 to 6 hours, before necrosis results. The goal is to give thrombolytics within 30 minutes of arrival at the emergency department door. Glycoprotein 11b/111a inhibitors (Eptifibatide [Integrilin], abciximab [ReoPro], tirofiban [Aggrastat]) are examples of IV medication that can be used as an adjunct to thrombolysis or PCI in patients with unstable angina or non–ST-segment-elevation MI. These drugs work by inhibiting platelet aggregation and are used along with aspirin or Plavix, and heparin.

ACTIVITY. Initially, patients are kept on bed rest to decrease myocardial oxygen demand. A bedside commode for bowel movements is usually ordered to reduce straining. Then activity is advanced gradually as tolerated.

INTRA-AORTIC BALLOON PUMP. To support the ischemic heart, an intra-aortic balloon pump (IABP) may be used to increase circulation to the coronary arteries and reduce the work of the heart (see Chapter 26). While the heart is relax ed (diastole), the balloon is inflated, sending more blood into the coronary arteries. Just before the heart contracts (systole), the balloon deflates, creating a suction effect that allows blood to flow past it with less resistance (decreased afterload) into the aorta.

**ANALGESICS.** Analgesics are given for relief of chest pain. Morphine sulfate is the most commonly used narcotic. It is usually given in increments of 2 to 8 mg IV every 5 to 15 minutes until pain is relieved. The patients should be monitored for hypotension, respiratory depression, oversedation, and morphine sensitivity. In addition to pain relief, morphine helps decrease anxiety, opens bronchioles, and increases peripheral blood pooling to decrease preload (blood returning to heart) and afterload (pressure within the aorta), which can help increase blood supply and oxygen to the myocardium.
GLUCOSE CONTROL. Guidelines for managing hyperglycemia in critically ill patients are to maintain blood glucose levels at 140 to 180 mg/dL and avoid hypoglycemia. Strict glycemic control has been shown to increase the risk of death at 90 days (Dechant, 2012).

DIET AND WEIGHT LOSS. During the acute phase of an MI, small, easily digested meals are served. Caffeine is restricted because it increases heart rate and causes vasoconstriction. Fluids may be restricted if the patient is in heart failure as well. Initially a low-sodium clear liquid diet may be ordered. Then a heart-healthy diet may be ordered. If the patient is obese, weight loss can reduce cardiac workload. A dietitian can work with the patient and family to devise a weight-loss diet for the patient.

TOBACCO USE. Patients are instructed on the hazards of smoking or exposure to secondhand smoke. Referral to a tobacco cessation program can be made. The nurse can help patients understand and accept lifestyle changes.

Coronary Artery Bypass Graft
AHA guidelines help determine which type of procedure would benefit the patient, PCI or coronary artery bypass graft (CABG). During bypass surgery, the saphenous vein from the leg or an internal mammary artery from the chest wall is used to reroute blood around a segment of a coronary artery that is narrowed by atherosclerosis (Fig. 24.8). One or more vessels can be bypassed (see “Patient Perspective”). There are two types of bypass procedures: arrested heart surgery and beating heart surgery.

ARRESTED HEART SURGERY. Most bypasses are done while the heart is stopped with a cardiopulmonary bypass machine (on pump) in use (see Chapter 21). While the median sternotomy is made, the vein graft is being removed from the body. The graft is flushed with a heparinized solution to check for leaks and then set aside for use during the surgery. After the patient is placed on cardiopulmonary bypass and the heart is stopped, one end of the graft is anastomosed (joined) to the coronary artery distal to the occlusion, while the proximal end of the graft is anastomosed, often to the ascending aorta.

BEATING HEART SURGERY. This surgery is done with the heart beating and does not use the heart-lung machine (off pump). A device is used to stabilize a vessel while the surgeon works on it. Either traditional median sternotomy or minimally invasive surgery can be used.

MINIMALLY INVASIVE SURGERY. Less invasive approaches include the minimally invasive coronary artery bypass grafting (MICS CABG), which is done off pump, and totally endoscopic coronary artery bypass surgery (TECAB), which
can be done on or off pump. MICS CABG is done through a small fifth intercostal incision. TECAB uses three or four chest holes for insertion of robotic arms and a camera that a surgeon then views to control the robotic arms.

### CRITICAL THINKING

**Mr. Jones**

- Mr. Jones is transferred to the critical care unit after a quadruple CABG. Preoperative vital signs were blood pressure 164/88 mm Hg, apical pulse 62 beats per minute and regular, respiratory rate 18 per minute, temperature 98.4°F (36.9°C). Data collection findings are blood pressure 100/56 mm Hg, apical pulse 105 beats per minute, and respiratory rate 28 per minute, irregular and shallow, temperature 99.8°F (37.7°C), lung sounds diminished with crackles in bilateral bases, pedal pulses weak bilaterally, chest and leg dressings dry and intact, and no urinary catheter. Mr. Jones is being monitored for first postoperative voiding.

1. Which findings may indicate pulmonary problems?
2. List four nursing interventions for the altered pulmonary status.
3. List three reasons why the apical pulse could be elevated.
4. Name two reasons why the blood pressure could be low.
5. With which health care team members will the nurse collaborate?

*Suggested answers are at the end of the chapter.*

### EVIDENCE-BASED PRACTICE

**Clinical Question**

Do depression, stress, or other psychological stressors have an effect on patients with CVD?

**Evidence**

Depression is a risk factor for the development of CVD in healthy people and is predictive of adverse outcomes. Depression is more prevalent in populations with CVD. Poor health behaviors contribute to this association (Whooley & Wong, 2013). A study of 176 subjects showed a relationship between left ventricular ejection fraction (LVEF) and depression 3 months after an MI (Bagherian-Sararoudi, Gilani, & Bahrami Ehsan, 2013).

**Implications for Nursing Practice**

Depression affects a patient’s adherence to post-MI lifestyle changes and medication adherence. After an MI, patients should be screened for depression, anxiety, sleep disorders, and social isolation at regular intervals during hospitalization and cardiovascular rehabilitation.

**REFERENCES**

### NURSING CARE TIP

When caring for a patient after a CABG, be sure to use infection-control procedures at all times to prevent surgical site infection. Surgical site infection following CABG (mediastinitis) is a “Never Event,” which means that Medicare will not pay the hospital for care required for this condition.

### Patient Education

Teaching about the therapeutic regimen includes information about the disease, medications, diet, activity, and rehabilitation needs that may require lifestyle changes. Diet, stress reduction, a regular exercise program, smoking cessation (if necessary), and following a medication schedule require extensive patient and family teaching. This disease can affect all aspects of a patient’s lifestyle. Issues about family and job roles and sexual activities need to be addressed. Patients need time to understand information that has been presented and should be encouraged to express any questions, needs, or fears.
Cardiac Rehabilitation and Exercise

Cardiac rehabilitation begins when the patient’s acute symptoms are relieved to improve cardiac function and quality of life. Phase 1 of rehabilitation occurs in the hospital. Activities for each hospital day, such as types and amounts of self-care and activity, are specified in protocols. Phase 2 occurs 4 to 6 weeks after discharge in an outpatient program and focuses on returning the patient to previous levels of activity and function. Phase 3 follows in which patients are encouraged to maintain optimal physical fitness and to continue healthy lifestyles that include exercising and losing weight to maintain an ideal body weight.

CRITICAL THINKING

Mrs. Sims

Mrs. Sims, age 43, is admitted to the ICU with a diagnosis of atypical chest pain that radiates to her left shoulder and down her left arm. She has a history of midsternal chest cramping. Her pain increases with activity and decreases with rest. She smokes one and a half packs of cigarettes per day and is 50 pounds overweight. The cardiac monitor shows normal sinus rhythm without dysrhythmias. She has NTG sublingual ordered prn (as needed) for chest pain.

One hour after admission, Mrs. Sims reports acute midsternal chest pain radiating to her left neck and jaw. The cardiac monitor shows sinus tachycardia with occasional premature ventricular contractions (PVCs). Her blood pressure is 100/70 mm Hg, respirations are 20 per minute and unlabored, and skin is warm and dry.

1. What actions should be taken?
2. What is happening to Mrs. Sims?
3. How is angina differentiated from an MI?
4. What are four indicators of an MI?
5. What medical interventions can be used for an MI?
6. What patient-centered education is indicated for Mrs. Sims?

Suggested answers are at the end of the chapter.

NURSING CARE PLAN for the Patient With Myocardial Infarction

Nursing Diagnosis: Acute Pain related to decreased coronary blood flow causing myocardial ischemia

Expected Outcomes: The patient will exhibit signs of decreased pain. Patient will exhibit signs of relaxation.

Evaluation of Outcomes: Does patient state that pain is reduced?

Intervention Monitor location, duration, intensity, and radiation of pain; use a scale of 0 to 10. Rationale Identifies type and severity of pain. Evaluation What is pain level, location, duration, intensity, and radiation?

Intervention Monitor blood pressure, pulse, and respiration. Rationale Vital signs may elevate with episodes of pain. Evaluation Are vital signs within normal limits?

Intervention Obtain ECG as ordered. Rationale Identifies location of infarction or ischemia. Evaluation Is ECG normal?

Intervention Administer oxygen as ordered. Rationale Helps prevent hypoxia. Evaluation Are ABGs within normal limits? Is oxygen saturation greater than 90%?

Intervention Instruct patient to report pain at first onset. Rationale Helps control pain quickly to prevent further ischemia. Evaluation Does patient report pain?

Intervention Instruct patient to rest during pain. Rationale Activity increases oxygen demand and can increase chest pain. Evaluation Does patient remain quiet and relaxed?

Intervention Remain with patient during chest pain until it is relieved. Rationale Provides comfort and reassurance to decrease anxiety and fear. Evaluation Are anxiety and fear decreased?

Intervention Assist with alternative pain relief measures; related to positioning, diversional activities, relaxation techniques. Rationale These measures help decrease painful stimuli, allowing the patient to focus on other things. Evaluation Does patient express relief and decreased stress?

Intervention Medicate as ordered. Rationale Helps eliminate pain. Evaluation Is pain relieved?
### NURSING CARE PLAN for the Patient With Myocardial Infarction—cont’d

#### GERIATRIC

**Intervention** Monitor and ensure that older patient’s pain is relieved. **Rationale** Pain is not an expected part of the aging process as many believe. **Evaluation** Does patient report pain is relieved?

#### Nursing Diagnosis: Decreased Cardiac Output related to ischemia or infarction, changes in heart rate and rhythm, and decreased contractility

**Expected Outcomes:** The patient will maintain adequate cardiac output and tissue perfusion. Patient will exhibit signs of improved cardiac output and tissue perfusion.

**Evaluation of Outcomes:** Does patient have heart rate greater than 60 and less than 100 beats per minute, blood pressure greater than 90/60 and less than 140/90 mm Hg, and urine output greater than 30 mL/hr?

**Intervention** Monitor blood pressure, heart rate, and urine output. **Rationale** Indirect indicators of cardiac output. **Evaluation** Are indicators within normal limits?

**Intervention** Listen to lung sounds. **Rationale** Crackles indicate heart failure. **Evaluation** Are lungs clear?

**Intervention** Monitor peripheral circulation, pulses, capillary refill, edema, color, and temperature. **Rationale** Indicators of adequate tissue perfusion. **Evaluation** Does patient have strong peripheral pulses, capillary refill less than 3 seconds, no edema, warm skin, pink nailbeds?

**Intervention** Monitor ECG. **Rationale** Identifies dysrhythmias. **Evaluation** Is patient’s ECG within normal limits?

**Intervention** Administer medications, such as vasodilators, beta blockers, calcium channel blockers, and cardiac glycosides, as ordered by HCP. **Rationale** Helps improve contractility, cardiac output, and tissue perfusion. **Evaluation** Does patient show signs of improved contractility, increased cardiac output, and tissue perfusion?

**Intervention** Promote and provide for adequate rest, quiet environment, bedrest; place in semi-Fowler’s position. **Rationale** Decreases cardiac workload and stress and allows for improved breathing. **Evaluation** Is patient relaxed?

**GERIATRIC**

**Intervention** Observe for atypical pain such as jaw pain or no pain with dyspnea or fatigue. **Rationale** In acute MI, older adults may not have had typical chest pain or have had a silent MI. **Evaluation** Does patient have atypical symptoms of MI?

**Intervention** Observe patient carefully for side effects of medications. **Rationale** Older patients are more likely to have medication toxicity owing to reduced renal and hepatic function. **Evaluation** Does patient exhibit toxic side effects of medications?

#### Nursing Diagnosis: Fear related to threat of death, changes in lifestyle, chest pain, and procedures

**Expected Outcomes:** The patient will verbalize reduced fear. Patient will demonstrate effective coping mechanisms.

**Evaluation of Outcomes:** Does patient verbalize reduced fear?

**Intervention** Assess level of fear and note nonverbal communication. **Rationale** Controlling anxiety will reduce sympathetic activity that may intensify condition. **Evaluation** Does patient report fear or have signs of being fearful?

**Intervention** Ask the patient’s usual coping pattern. **Rationale** This allows building on patient’s strengths. **Evaluation** What are patient’s coping techniques?
**NURSING CARE PLAN for the Patient With Myocardial Infarction—cont’d**

**Intervention** Orient the patient and family to surroundings and equipment, oxygen, cardiac monitoring, IVs, and explain procedures. **Rationale** Information may promote trust and reduce emotional stress. **Evaluation** Does patient state understanding of environment and equipment?

**Intervention** Assure patient he/she will be closely monitored. **Rationale** Assurance of detection for prompt treatment of any complications will reduce fear. **Evaluation** Does patient state less fear due to continuous monitoring?

**Intervention** Allow patient to verbalize fear of dying. **Rationale** Ventilation helps identify and reduce fear. **Evaluation** Is patient able to verbalize fears?

**Intervention** Provide diversional materials such as newspapers, music, and television. **Rationale** Diversion can be relaxing and prevent feelings of isolation. **Evaluation** Does patient report that use of diversional activities reduces fear?

**Intervention** Offer family support. **Rationale** Significant others often ignore their own needs, experience anxiety, and need support, including ongoing information and explanations, being allowed to stay with patient, and being involved in patient’s care. Nurses need to help spouses or significant others meet their own needs, so they can better support the patient. **Evaluation** Does family verbalize ability to offer support to patient without anxiety?

**GERIATRIC**

**Intervention** Provide protective, safe environment with consistent caregivers. **Rationale** Older adults adapt to change with more difficulty during illness than younger adults. **Evaluation** Is continuity of care provided? Does patient report less fear?

**Nursing Diagnosis:**  *Activity Intolerance* related to imbalance between oxygen supply and demand, weakness, and fatigue

**Expected Outcome:** The patient will tolerate progressive activity as evidenced by heart rate, blood pressure, pulse oximetry, and respiratory rate within normal limits (WNL).

**Evaluation of Outcome:** Is patient’s heart rate, blood pressure, pulse oximetry, and respiratory rate WNL with progressive activity?

**Intervention** Obtain patient’s vital signs before activity. **Rationale** Identifies baseline data comparison with activity. **Evaluation** What are vital signs?

**Intervention** Observe patient during and after activity and document abnormal responses to activity, including heart rate over 120 beats per minute or 20 beats over resting rate, systolic BP increased over 20 mm Hg during activity, chest pain, dizziness, skin color changes, diaphoresis, dyspnea, dysrhythmias, excessive fatigue, and ST-segment changes on ECG. **Rationale** Observation allows detection of abnormal responses to stop activity. **Evaluation** Are vital signs WNL? Is activity tolerated without symptoms?

**Intervention** Position patient for comfort and ease in breathing. **Rationale** Semi-Fowler’s position is usually preferred by patients in respiratory distress. When patient is sitting upright in bed, supporting arms on pillows reduces cardiac workload by eliminating force of gravity on unsupported arms. **Evaluation** Is patient able to breathe easily?

**Intervention** Maintain progression of activities as ordered by HCP or cardiac rehabilitation program. *Initial activities:* ADLs, dangle at bedside for 15 minutes, use commode with assistance. *Progressive activities:* Out of bed to chair for 30 to 60 minutes, partial bath, range-of-motion exercises. **Rationale** The patient should have increasing activity to condition the myocardium. **Evaluation** Is patient able to progress activity?
NURSING CARE PLAN for the Patient With Myocardial Infarction—cont’d

GERIATRIC

Intervention: Slow the pace of care. Rationale: Allow patient extra time to complete activity to reduce cardiac demand and fatigue. Evaluation: Is patient able to complete care without symptoms or fatigue?

Intervention: Refer patient to cardiac rehabilitation as able. Rationale: Older adults benefit comparably to younger persons from exercise programs. Evaluation: Does patient participate in cardiac rehab?

Intervention: Encourage families to let patient be independent in activities. Rationale: Families may believe being sedentary is helpful to the patient. Evaluation: Do family members encourage patient to be as active as able?

NURSING CARE PLAN for the Patient Undergoing Cardiac Surgery

Nursing Diagnosis: Acute Pain related to sternotomy, leg incisions, internal mammary artery resection, or pericarditis

Expected Outcomes: The patient will state pain is relieved or tolerable. Patient will be able to rest and perform respiratory treatments.

Evaluation of Outcomes: Does patient state pain is within acceptable levels? Is patient able to rest and perform respiratory therapies?

Intervention: Assess characteristics of pain with each episode. Rationale: A thorough description is needed to determine cause and plan actions. Evaluation: Does patient describe pain on scale of 0 to 10?

Intervention: Encourage patient to report pain even when it is mild. Rationale: It is easier to keep pain under control when mild. Evaluation: Does patient report pain when mild?

Intervention: Turn, reposition every 2 hours. Rationale: Changes muscle position, relieving stiffness. Evaluation: Is patient comfortable without stiffness?

Intervention: Offer back rubs frequently. Rationale: Relaxes tense muscles retracted during operation. Evaluation: Is patient able to rest comfortably?

Intervention: Teach patient “sternal precautions”: • No pushing or pulling with arms. • Hug pillow for all movement, coughing, and deep breathing. • Do not use arms to raise yourself out of a chair. • No lifting over 5 to 10 lb. • Do not raise elbows higher than shoulders. • Bend elbows and lower head for grooming. Rationale: Stabilizes sternum and incision to increase comfort. Evaluation: Does patient understand sternal precautions and use them?

Intervention: Instruct patient to take a deep breath before movement and exhale slowly during movement. Rationale: Keeps muscles relaxed, minimizing tension with guarding and pain. Evaluation: Can patient perform coughing and deep-breathing techniques as instructed?

Nursing Diagnosis: Decreased Cardiac Output related to myocardial depression, hypothermia, bleeding, unstable dysrhythmias, or hypoxemia

Expected Outcomes: The patient will remain free of major side effects of pharmacological support. Patient will maintain vital signs within normal limits (WNL), palpable peripheral pulses, urine output greater than 30 mL/hr, and normal sinus rhythm.

Continued
### Evaluation of Outcomes:

Is patient free of major side effects? Are vital signs WNL?

#### Intervention

**Monitor vital signs.**

**Rationale:** Trends reflect problems.

**Evaluation:** Are vital signs WNL?

**Check peripheral circulation.**

**Rationale:** Mottling or weak pulses may indicate poor cardiac output (CO).

**Evaluation:** Do peripheral pulses remain strong with normal skin color, temperature, capillary refill?

**Monitor intake and output.**

**Rationale:** Fluid deficit or excess can alter CO.

**Evaluation:** Does total intake equal output?

**Listen to lung sounds and note character of sputum.**

**Rationale:** Wet lung sounds may indicate heart failure or pulmonary edema.

**Evaluation:** Are lungs clear?

**Note shivering.**

**Rationale:** Shivering increases the blood pressure, decreasing CO and increasing risk for bleeding.

**Evaluation:** Is patient’s shivering controlled?

**Monitor chest tube drainage for increase or sudden decrease.**

**Rationale:** Drainage more than 200 mL/hr may lead to hypovolemia and a decrease in CO.

**Evaluation:** Is patient free from cardiac tamponade and hypovolemia?

**Monitor ECG.**

**Rationale:** Premature ventricular contractions and atrial fibrillation decrease CO.

**Evaluation:** Does patient remain in normal sinus rhythm or controlled dysrhythmia? (See Chapter 25.)

**Monitor electrolytes.**

**Rationale:** Low calcium and magnesium and high potassium decrease contractility and CO.

**Evaluation:** Are electrolytes WNL?

**Monitor ABGs.**

**Rationale:** Acidosis decreases heart function, and a low CO may lead to further acidosis.

**Evaluation:** Are ABGs WNL?

### Nursing Diagnosis:

**Risk for Infection** related to inadequate primary defenses from surgical wound.

#### Expected Outcome:

The patient will remain free from infection.

#### Evaluation of Outcome:

Does patient remain free from infection?

**Observe incision for signs and symptoms of infection.**

**Rationale:** Redness, warmth, fever, and swelling indicate infection.

**Evaluation:** Are signs and symptoms of infection present?

**Monitor drainage and maintain drains.**

**Rationale:** Drains remove fluid from the surgical site to prevent infection development.

**Evaluation:** Are drainage amount and color normal for procedure? Are drains functioning?

**Maintain sterile technique for dressing changes.**

**Rationale:** Sterile technique reduces infection development.

**Evaluation:** Is incision free of signs and symptoms of infection?

**Monitor and report abnormal findings for temperature, lung sounds, sputum, and urine consistency.**

**Rationale:** Low-grade or high-grade fever, crackles, yellow-green sputum color, or cloudy urine can indicate infection.

**Evaluation:** Is the patient’s temperature WNL and are lung sounds, sputum, and urine clear?

**Encourage coughing and deep breathing and incentive spirometer use.**

**Rationale:** Lung infections can be prevented with lung expansion and secretion removal.

**Evaluation:** Does patient perform coughing and deep breathing and use incentive spirometer?
Peripheral Vascular System

Peripheral vascular disease (PVD) may be either arterial or venous in origin. PVD is common in older people and people with diabetes. It is important for the nurse to understand whether the origin of the problem is arterial or venous to prevent serious complications from occurring.

Arterial Thrombosis and Embolism

Pathophysiology

Acute arterial occlusions are often sudden and dramatic. Occlusions are most common in the lower extremity but may occur in the upper extremity as well. A thrombus (blood clot) adheres to the vessel wall. Acute arterial thrombi occur where there is injury to an arterial wall, sluggish flow, or plaque formation secondary to atherosclerotic changes. Other causes of arterial thrombosis are polycythemia, dehydration, and repeated arterial needlesticks. If a thrombus breaks off and travels, it becomes an embolism that occludes an arterial vessel that is too small to allow it to pass. Some of the causes of an arterial embolism are dysrhythmias, prosthetic heart valves, MI, and rheumatic heart disease.

Signs and Symptoms

Usually there is an abrupt onset of symptoms with acute arterial occlusion. If a patient also has chronic arterial insufficiency, the symptoms may not occur as rapidly because collateral circulation has developed and can supply some blood to the occluded area. Symptoms depend on the artery occluded, the tissue supplied by that artery, and whether collateral circulation is present.

The six clinical signs of acute arterial occlusion are known as the "six Ps": pain, pallor, pulselessness, paresthesia (numbness), paralysis, and poikilothermia (temperature). The patient experiences pain, numbness, and decreased movement in the extremity, which is pale, mottled and without pulses distal to the occlusion. The extremity feels cold because blood normally provides warmth. If treatment is not initiated immediately, ischemia occurs and can progress to tissue necrosis and gangrene development within hours.

Therapeutic Measures

Early treatment is necessary to protect and save the affected limb. Anticoagulant therapy is started immediately. IV heparin is the treatment of choice to prevent further clotting. Heparin has no effect on existing clots. An initial IV bolus of heparin, usually 5000 international units, is given. An IV infusion is then started as ordered. The patient remains on heparin therapy for several days. Daily heparin Xa or PTTs are monitored to maintain therapeutic heparin levels. After 3 to 7 days, typically warfarin (Coumadin) is added. Warfarin, an oral anticoagulant, takes 3 to 5 days to reach therapeutic levels. The heparin is continued until a therapeutic warfarin level is reached. To monitor warfarin’s effects, international normalized ratios (INRs) and prothrombin times (PTs) are done daily, and adjustments in warfarin doses are made based on the results.

For patients with severe occlusions, especially if the risk of limb loss is imminent, surgery or thrombolytic agents are used to save the extremity. During an emergency embolectomy or thrombectomy, the artery is cut open, the emboli or thrombus is removed, and the vessel is sutured closed. Thrombolytic agents dissolve the thrombus or embolus.

Peripheral Arterial Disease

Peripheral arterial disease (PAD) is a disorder of the arterial circulation usually caused by chronic, progressive narrowing of arterial vessels that leads to obstruction or occlusion. PAD usually affects the lower extremities. PAD is sometimes referred to as lower extremity arterial disease (LEAD). Atherosclerosis is the leading cause of occlusive disease. PAD can be described as organic or functional. Organic disease is caused by structural changes from plaque or inflammation in the blood vessels. Functional disease is a short-term localized spasm in the blood vessel as noted in Raynaud’s disease.

Pathophysiology

The purpose of the arterial system is to deliver oxygen-rich blood to the vascular beds. Anything that impedes this flow causes an imbalance in supply and demand for oxygen. Decreased nutrition, cellular waste accumulation, and the development of ischemia occur at the area distal to the obstruction. With the increased debris and sluggish flow, thrombosis and embolism can become major problems.

Critical Thinking

Mrs. May

Mrs. May is admitted with severe rheumatoid arthritis, which has left her relatively immobile for 7 months. She is returning to her room following a whirlpool treatment when she suddenly reports severe pain in her left groin.

1. What is your first action?
2. After assessing Mrs. May, what action should be taken next?
3. What are the possible causes of these sudden symptoms?
4. How would you document Mrs. May’s symptoms?
5. What immediate interventions are necessary?
6. What medical interventions would you anticipate?
7. What surgical procedure may need to be done if the risk of losing the limb is imminent?

Suggested answers are at the end of the chapter.

The body has several mechanisms that attempt to compensate for reduced blood flow, including peripheral vasodilation, anaerobic metabolism, and development of collateral circulation. However, these mechanisms are not intended to meet the ongoing blood supply needs of the body. It takes time for collateral circulation to develop, blood vessels eventually reach their limit of dilation, and anaerobic metabolism is only a very short-term compensatory mechanism. Eventually this lack of blood supply produces signs of ischemia that,
if not corrected, result in ulceration, gangrene, and necrosis of the extremity; amputation of the limb may then become necessary.

**Signs and Symptoms**

Many people with PAD, especially women, have no symptoms. Symptoms often occur late in the course of PAD when diminished blood flow begins to produce changes in the extremities. Pain in the calves associated with activity or exercise, called *intermittent claudication,* is a common symptom of arterial occlusive disease. When blood supply to the muscles is decreased, the muscles are unable to receive adequate oxygen, and ischemia develops. As ischemia increases, the muscle develops a cramping-type pain that usually subsides when the activity is stopped. As PAD progresses, the pain is present even at rest, thus indicating severe arterial occlusion.

Skin color changes are associated with decreased blood supply. The extremity is pale when the leg is elevated. If the leg is in a dependent position, it becomes reddish purple or cyanotic. The extremity is cool to touch even in warm environments. There may be hair loss on the lower calf, ankle, and foot. Other findings include dry, flaky, scaly, pale, or mottled skin. The toenails may be thickened. As occlusion of the arteries progresses, arterial pulses become diminished or absent. Pulses should be palpated in both legs. The loss of circulation leads to tissue death and gangrene.

**Diagnostic Tests**

Noninvasive studies can be used to diagnose occlusive disorders. The ABPI is used to determine pressures in the upper and lower extremities. Normally, blood pressure readings in the thigh and calf are higher than those in the upper extremities. With the presence of arterial disease, these pressures are lower than the brachial pressure. Normally the ankle pressure is equal to or greater than the brachial pressure. When an occlusion occurs in the lower extremities, the pressures between the upper and lower extremities become unequal. After treadmill exercise, the ABPI decreases in arterial insufficiency. A duplex ultrasound measures the velocity of the blood flow. MRI and CT scan can give definitive images of blood vessels and degrees of arterial closure. Plethysmography and angiography can also be used to evaluate arterial flow in lower extremities (see Chapter 21).

**Therapeutic Measures**

Conservative treatment is initiated with mild to moderate occlusive disease. This includes patients who experience pain on activity that ceases with rest. This type of patient usually receives medication for vasodilation and diet management if necessary. Surgical intervention is used for the patient who experiences pain at rest or who has leg ulcers that do not heal. Surgical treatment includes endarterectomy to remove atherosclerotic lesions, balloon angioplasty with stents, or grafting to bypass the occluded area. (See the discussion of vascular surgery later in this chapter.)

**Diet.** The diet should aim to control atherosclerosis development. Teaching the patient to eat a healthy diet is important.

**Medications.** Drug therapy is geared toward the symptoms and causes of the occlusive disease. The same drugs used to decrease cholesterol and lipids are used in atherosclerosis are used with occlusive disease. Pentoxifylline (Trental) or cilostazol (Pletal) is used for patients with occlusive disorders who experience intermittent claudication. Trental makes red blood cells more flexible to improve perfusion. Pletal is an antiplatelet medication. The major side effect is gastrointestinal upset, so it should be taken with meals. Thrombolytic therapy is used when an occlusion is caused by a thrombus or an embolus.

**Invasive Therapies.** Percutaneous transluminal angioplasty (PTA) can be used to dilate a narrowed peripheral vessel, although it does not provide long-term results. It is similar to PCI, which was discussed earlier. Peripheral atherectomy is another invasive procedure used to remove plaque from atherosclerotic arteries. Intravascular stents can also be used to maintain patency of the artery. After stent placement, patients are given platelet aggregation inhibitors.

**Raynaud’s Disease**

A vasoconstrictive response causing ischemia from exposure to cold and stress is known as Raynaud’s disease or syndrome. It occurs more often in women who live in cold climates. Raynaud’s disease primarily affects the hands but can also occur in the feet, ears, or nose. To be diagnosed with Raynaud’s disease, the patient must experience intermittent attacks of ischemia for at least 2 years.

**Pathophysiology**

Raynaud’s disease is characterized by spasms of small arteries in the digits. These spasms prevent arterial blood from perfusing the fingertips and sometimes the toes. The spasms can occur unilaterally and in one or two digits, but most often they occur bilaterally and in all digits. Raynaud’s disease may be seen with collagen diseases such as rheumatoid arthritis, scleroderma, and systemic lupus erythematosus. This disease can progress over time; the vessels remain constricted and the severe decrease in blood flow can lead to fingers becoming gangrenous and necrotic.

**Signs and Symptoms**

The hands, when exposed to cold, exhibit vascular spasms and a marked decrease in blood flow to the tissues. The resulting effect in the tissues is ischemic pain. After several minutes of ischemia, hyperemia occurs. Hyperemia is intense reddening of the hands from dilation of all the vessels of the hands. Pain becomes more intense at this time. Patients with Raynaud’s disease go through various phases, which include blanching of the skin, pain, and reddening of the skin.

**Therapeutic Measures**

Conservative treatment is attempted first. The patient is instructed to keep the hands warm. Gloves should be worn when going outside, cleaning a refrigerator, or preparing cold foods. Patients are instructed in the importance of protecting the hands from injury and avoiding things that contribute to
vasoconstriction, such as smoking, alcohol, and caffeine. Reducing stress levels can also help prevent vasoconstriction. Immersing the hands in warm water may decrease the vasospasm. Vasodilators are sometimes prescribed to help the patient avoid peripheral vasoconstriction. Raynaud’s disease is treated surgically with a sympathectomy. This blocks the sympathetic reflex.

**Nursing Care**

Education is essential for patients with Raynaud’s disease. Teaching the patient to protect the hands is important. Stressing the use of gloves in cold climates, reducing vasoconstrictive activity, and decreasing stress levels helps reduce the number and severity of attacks.

**Thromboangiitis Obliterans (Buerger’s Disease)**

Buerger’s disease is a recurring inflammation and thrombosis of small and medium arteries and veins of the hands and feet. It is associated with tobacco use, both cigarettes and smokeless tobacco. The cause is unknown, but it is thought to be an autoimmune disorder. It is most prevalent in young men between ages 25 and 40. It is increasing in women likely due to increased tobacco use by women.

Intermittent claudication and other symptoms of occlusive disease are common in patients with Buerger’s disease. Other symptoms include numbness or decreased sensation and cool extremities. Lower extremities can be red or cyanotic when in a dependent position, and pulses may be diminished. Depending on the degree of ischemia, ulceration or gangrene may be present.

Because the primary contributing factor is smoking, there is urgency in helping the patient to cease smoking and avoid secondhand smoke. The patient must be made aware of the effect smoking has on the body and that the disease will progress and further damage other vessels. There is no cure or effective treatment. The use of calcium channel blockers such as diltiazem (Cardizem) promotes vasodilation and may help with intermittent claudication. Surgery is not effective. Supportive therapy and nursing care for Buerger’s disease is used with the goal of reducing complications of ulceration, gangrene, and amputation. Careful inspection of the lower extremities for signs of breakdown is important, so early treatment can begin.

**Nursing Process for the Patient With a Peripheral Arterial Disorder**

**DATA COLLECTION.** Monitoring peripheral circulation is most important for patients with arterial occlusive disorders. Careful assessment of pulses, capillary refill, temperature, color, and presence of edema helps identify patients at risk for complications. Absent pulses are reported immediately to prevent limb loss. Skin that is shiny and hairless points to chronic diminished blood flow to the extremity. Laboratory blood testing is not necessary to test for peripheral arterial disease, but a lipid panel and serum glucose can identify diabetes, which is a significant risk factor for PAD. The presence of skin lesions and ulcerations is noted.

**NURSING DIAGNOSES, PLANNING, IMPLEMENTATION, AND EVALUATION.** See the “Nursing Care Plan for the Patient With a Peripheral Arterial Occlusive Disorder.”

---

**NURSING CARE PLAN for the Patient With a Peripheral Arterial Occlusive Disorder**

**Nursing Diagnosis:** *Acute Pain* related to impaired circulation to extremities causing intermittent or continuous pain

**Expected Outcome:** The patient will report that pain is controlled at an acceptable level.

**Evaluation of Outcome:** Does patient report relief from pain by nonpharmacological or pharmacological methods?

**Intervention** Note peripheral circulation, pulses, color, temperature, presence of edema, and skin breakdown. **Rationale** Determines the degree of tissue perfusion and complications. **Evaluation** Does patient have pulses, warm skin, capillary refill less than 3 seconds, no evidence of skin breakdown?

**Intervention** Monitor for intermittent claudication or pain at rest. **Rationale** Helps determine degree of occlusive disease. Pain at rest is an indicator that the arterial occlusion is becoming worse. **Evaluation** Does patient have pain during activity or at rest?

**Intervention** Administer medication as ordered: • Analgesics • Vasodilators • Calcium channel blockers **Rationale** Relieves chronic or acute pain. Increases blood flow to extremities. Decrease vasospastic episodes. **Evaluation** Does patient show signs of increased circulation and relief of pain following administration of medications?
## NURSING CARE PLAN for the Patient With a Peripheral Arterial Occlusive Disorder—cont’d

**Intervention** Encourage rest if pain is present. **Rationale** Rest decreases muscle contraction and prevents further ischemia in extremities. **Evaluation** Is patient able to rest?

**Intervention** Position lower extremities below heart level. **Rationale** Increases arterial flow to lower extremities. **Evaluation** Are pulses strong, capillary refill less than 3 seconds, extremities pink and warm?

**Intervention** Protect extremities from cold or trauma. **Rationale** Extremities with decreased circulation have decreased sensation, which increases risk of injury. **Evaluation** Are extremities injury-free?

**Intervention** Teach the patient importance and use of relaxation techniques. **Rationale** Relaxation will decrease the stress response and vasoconstriction related to catecholamine release. **Evaluation** Does patient demonstrate use of relaxation techniques?

**Nursing Diagnosis:** Ineffective Tissue Perfusion related to interruption of arterial flow in arms and legs

**Expected Outcome:** The patient will show signs of increased arterial blood flow and tissue perfusion.

**Evaluation of Outcome:** Does patient have strong peripheral pulses, capillary refill less than 3 seconds, warm skin, absence of edema?

**Intervention** Check peripheral pulses, capillary refill, color, temperature, and presence of edema every 4 hours. **Rationale** Indication of adequate tissue perfusion. **Evaluation** Are peripheral pulses strong, nail beds pink, capillary refill less than 3 seconds with no edema noted?

**Intervention** Report absent or diminished pulses immediately. **Rationale** Indication of inadequate tissue perfusion requiring immediate treatment. **Evaluation** Are peripheral pulses present and strong?

**Intervention** Check skin for intactness, healed areas, signs of ulceration or infection. **Rationale** Chronic arterial occlusion leads to decreased blood flow, resulting in tissue damage and poor wound healing. **Evaluation** Is skin intact?

**Intervention** Place extremities lower than heart, feet on floor in sitting position, head of bed elevated on blocks. **Rationale** Dependent position increases blood flow to the legs and feet. **Evaluation** Does patient have adequate tissue perfusion signs?

**Intervention** Avoid bending knees, pillows under knees, prolonged sitting, or crossing legs. **Rationale** These activities impede blood flow to extremities. **Evaluation** Does patient exhibit understanding of improving blood flow?

**Intervention** Inspect lower extremities frequently. Clean feet with mild soap; dry carefully. Protect from injury. **Rationale** Cleaning prevents trauma to feet, protecting feet from things that can lead to ulcerations. **Evaluation** Is patient free from trauma or breaks in skin of the lower extremities?

**Intervention** Encourage use of shoes that fit well. **Rationale** Prevents irritation and tissue breakdown leading to ulcer. **Evaluation** Does patient verbalize that shoes fit well?

**Intervention** Refer to progressive activity program. **Rationale** Gradual progressive exercise promotes collateral circulation. **Evaluation** Does patient participate in exercise program?

**Intervention** Keep extremity warm with socks and blankets. **Rationale** Prevents vasoconstriction and promotes comfort. **Evaluation** Are extremities warm?

**Nursing Diagnosis:** Activity Intolerance related to activity pain and diminished blood flow

**Expected Outcome:** The patient will report that pain is relieved during desired activities.
### NURSING CARE PLAN for the Patient With a Peripheral Arterial Occlusive Disorder—cont’d

**Evaluation of Outcome:** Does patient participate in activities without pain?

**Intervention** Begin walking program: Start on flat surface. Walk 30 minutes per day. **Rationale** Promotes collateral circulation without greatly increasing oxygen demand. **Evaluation** Does patient participate in walking program?

**Intervention** Walk every day, increasing the distance in small increments until experiencing claudication. Walk one-half city block after pain begins per HCP order. Stop and rest until pain subsides. **Rationale** Walking through the pain will promote collateral circulation. Pain should subside with rest. **Evaluation** Does patient increase distance with claudication? Does pain stop with rest?

**Nursing Diagnosis:** Deficient Knowledge: peripheral arterial disease related to complications, medications, or postoperative care

**Expected Outcome:** The patient and family will verbalize self-care measures to control disease and prevent complications.

**Evaluation of Outcome:** Do patient and family verbalize understanding of teaching?

**Intervention** Ask patient’s and family’s knowledge of the physiology of the disease, and treatment and preventive techniques. **Rationale** This will determine educational topics. **Evaluation** What is patient’s and family’s baseline knowledge of peripheral artery disease (PAD)?

**Intervention** Describe peripheral arterial disease, symptoms, diagnosis, treatment, and complications to patient and family. **Rationale** The patient should understand PAD to help control disorder. **Evaluation** Do patient and family verbalize understanding of PAD?

**Intervention** Teach healthy lifestyle and risk factor control: smoking cessation, healthy diet, walking programs, hyperlipidemia, and diabetes and hypertension control. **Rationale** Healthy lifestyle promotes circulation and decreases functional impairment and pain. **Evaluation** Is patient willing and able to incorporated healthy lifestyle into daily routine?

**Intervention** Explain daily foot care: • Inspect feet for ingrown toenails, redness, sores, or blisters, wash feet with warm soap and water, dry with gentle patting, lubricate skin to prevent cracking, wear clean socks. **Rationale** Daily foot care and reporting problems promptly can help prevent complications of PAD. **Evaluation** Does patient state that he or she will perform daily foot care and verbalize understanding?

**Intervention** • Do not walk barefoot, and inspect inside of footwear for foreign objects before inserting foot. **Rationale** Ulceration of the toes may follow trauma if foreign object is walked on, which can result in infection. **Evaluation** Does patient verbalize understanding of need to protect feet?

**Intervention** Explain prescribed drug treatment protocols. **Rationale** Medication explanation can help patient comply with therapy. **Evaluation** Does patient verbalize understanding of medications?

### Aneurysms

An aneurysm is a bulging, ballooning, or dilation at a weakened point of an artery. The artery diameter is often increased by 50%. The cause is unknown, but anything that weakens the artery wall or causes loss of elasticity in the artery can cause an aneurysm. Atherosclerosis, hypertension, smoking, trauma, and congenital abnormalities are risk factors for an aneurysm. Heredity may also play a role.

Smoking is such a risk factor that Medicare allows a one-time screening for those over 65 with a smoking history. Aneurysms can occur in any artery in the body but are common in the abdominal aorta, which is the focus of the rest of this discussion.

**WORD BUILDING**

hyper—above + lipos—fat + emia—blood
An abdominal aortic aneurysm (AAA) is often silent if it is less than 4 cm. Men older than age 50 are at the highest risk of death from an AAA. The incidence of AAA increases with age. Survival improves with elective repair rather than having emergency surgery after the aneurysm ruptures.

Types of Aneurysms
The various types of aneurysms are shown in Figure 24.9. A fusiform aneurysm is the dilation of the entire circumference of the artery. A saccular aneurysm is one that bulges on only one side of the artery wall. A dissecting aneurysm occurs when a cavity is formed from a tear in the artery wall, usually the intimal (inner) layer. The layers of the artery are then separated as blood is pumped into the tear with each heartbeat, expanding the cavity, which is then prone to rupturing.

Signs and Symptoms
Aneurysms usually exhibit few if any symptoms (Table 24.8). As the AAA grows, symptoms may develop. Back or flank pain is the classic symptom; the pain is caused by the aneurysm pressing against nerves of the vertebrae. Depending on the location and size of the aneurysm, there may be reports of abdominal pain, a feeling of fullness, or nausea caused by pressure on the intestines. The pain may mimic pain associated with any abdominal or back disorder. Changing positions may temporarily relieve the symptoms. Because the symptoms are vague, they are often not associated with an AAA. There may be a pulsating mass in the abdomen caused by an AAA that is discovered during routine physical or x-ray examination.

Severe, sudden back, flank, or abdominal pain and a pulsating abdominal mass can indicate that the aneurysm may be about to rupture. With rupture, the patient’s blood pressure may drop and signs of shock may be present. Immediate surgery is needed for a ruptured AAA. The mortality rate is high with a ruptured aneurysm.

Diagnostic Tests
Abdominal ultrasound, CT scan, MRA, or aortography can be done to diagnose an AAA. Small aneurysms are watched, usually with ultrasound every 6 to 12 months, for enlargement.

Therapeutic Measures
Medical treatment consists of medication to maintain lower blood pressures to prevent arterial wall to rupture. Surgical treatment—a bypass graft—is performed when the patient is experiencing pain, showing signs of circulatory compromise, or has an aneurysm that is larger than 5 cm, which increases the risk of rupture.

An endovascular stent graft or a conventional open surgical repair may be done for an AAA. Endovascular grafting involves the placement (through the femoral artery) of a stent graft at the site of the AAA. A balloon catheter positions and opens the graft. Blood flows through the stent graft to reduce pressure on the aneurysm, which will shrink over time. A fenestrated (perforated) endograft is used when the AAA is near other arteries such as the renal arteries to maintain their blood flow. Endovascular surgery requires less hospitalization time (2–3 days) and a quicker recovery.

**Nursing Process for the Patient With an Abdominal Aortic Aneurysm**

**DATA COLLECTION.** Careful monitoring of a patient with a AAA is necessary. Patient understanding must be assessed so patients know their medications and the importance of taking antihypertensives as prescribed. Stress may be a risk factor that should be addressed. Lifting heavy objects can increase pressure within the artery and may be restricted in the individual being treated with more conservative measures. Postoperatively, the patient should avoid lifting heavy objects (see “Home Health Hints”).

**FIGURE 24.9** Types of aneurysms. (A) Fusiform: The entire circumference of the artery is dilated. (B) Saccular: One side of the artery is dilated. (C) Dissecting: A tear in the inner layer causes a cavity to form between the layers of the artery and fill with blood. The cavity expands with each heartbeat.
Instruct the patient to report changes in skin color, monitor peripheral pulses and capillary refill to ensure adequate tissue perfusion. Report absent pulses or sluggish capillary refill to the patient's HCP. Instruct the patient to report changes in skin color, insect bites, and/or rashes to the HCP. Patients with peripheral vascular disorders are at a high risk for developing lower extremity wounds that are often slow to heal.

Vascular
- Instruct the patient to stop and rest if pain develops in the lower extremities during exercise.
- Monitor peripheral pulses and capillary refill to ensure adequate tissue perfusion. Report absent pulses or sluggish capillary refill to the patient's HCP.
- Instruct the patient to report changes in skin color, insect bites, and/or rashes to the HCP. Patients with peripheral vascular disorders are at a high risk for developing lower extremity wounds that are often slow to heal.

Etiology
Wall defects have been identified as a familial tendency and may be inherited. Any factor that contributes to increasing hydrostatic pressure within the leg, such as prolonged standing, pregnancy, and obesity, can promote venous dilation. Incompetent valves within the veins can cause blockage of blood flow and lead to dilated veins.

Therapeutic Measures
The primary goals are to improve circulation, relieve pain, and avoid complications. Conservative treatment is exercise, elevation, and elastic compression hose as ordered. Injection sclerotherapy or lasers treat superficial varicosities. Minimally invasive ablation procedures include radiofrequency ablation (closure procedure) or endovenous laser treatment.

Venous Insufficiency
Venous insufficiency is a chronic condition. Damaged or aging valves within the veins interfere with blood return to
the heart, causing pooling of blood in the lower extremities. Chronic venous insufficiency can lead to venous stasis ulcers.

**Venous Stasis Ulcers**

**PATHOPHYSIOLOGY.** Venous stasis ulcers are the end result of chronic venous insufficiency. Dysfunctional valves in the venous system prevent or reduce venous blood return. As venous pressure increases, venous stasis occurs. Over time the congestion and decreased venous circulation lead to changes in the lower extremities. There may be edema and a brownish discoloration of the leg and foot, with the surrounding skin hardened and leathery in appearance. The brown color occurs

</thead>
<tbody>
<tr>
<td><strong>Nursing Diagnosis:</strong> <em>Acute Pain</em> related to surgical incision and reperfusion of tissue</td>
</tr>
<tr>
<td><strong>Expected Outcomes:</strong> The patient will state that the pain is relieved or is tolerable within 30 minutes of pain report. The patient will rest comfortably, perform respiratory treatments as necessary, and perform activities of daily living (ADLs).</td>
</tr>
<tr>
<td><strong>Evaluation of Outcomes:</strong> Does patient state that pain is relieved or acceptable? Is patient able to rest and participate in respiratory treatments and ADLs?</td>
</tr>
<tr>
<td><strong>Intervention</strong> Ask about severity, as well as all other qualities, of pain. <strong>Rationale</strong> Peripheral vascular surgery pain is usually mild; severe pain may indicate reocclusion. Major vascular surgery pain is severe. <strong>Evaluation</strong> Does patient state that pain is at a tolerable level with a patent vessel?</td>
</tr>
<tr>
<td><strong>GERIATRIC</strong></td>
</tr>
<tr>
<td><strong>Intervention</strong> Ask patient to rate pain after analgesic is given. <strong>Rationale</strong> Pain relief is individualized. <strong>Evaluation</strong> Does patient state that pain is controlled at a tolerable level?</td>
</tr>
<tr>
<td><strong>Intervention</strong> Notify HCP if pain is unrelieved. <strong>Rationale</strong> Different analgesic may be needed to give relief. <strong>Evaluation</strong> Are patient’s pain relief needs met?</td>
</tr>
<tr>
<td><strong>Intervention</strong> Ensure that older patient’s pain is relieved. <strong>Rationale</strong> Pain is not a normal part of aging, and older patients need and are entitled to adequate pain relief. <strong>Evaluation</strong> Does patient rate pain as none or at a tolerable level using a scale of 0 to 10?</td>
</tr>
<tr>
<td><strong>Intervention</strong> Use opioid pain medications cautiously. Consider reducing frail older patients’ first opioid dose by 25% to 50%, and increase as safe and needed and as ordered. <strong>Rationale</strong> Older patients are more susceptible to peak effects and duration of analgesia of opioids. <strong>Evaluation</strong> Are patient’s vital signs and sedation levels within normal limits?</td>
</tr>
<tr>
<td><strong>Nursing Diagnosis:</strong> <em>Ineffective Tissue Perfusion</em> related to hypotension, hypothermia, emboli, vascular spasm, or reocclusion</td>
</tr>
<tr>
<td><strong>Expected Outcomes:</strong> The patient will have palpable peripheral pulses: adequate capillary refill, and normal color, temperature, motor, and sensory function of extremities. The patient will have reactive pupils and baseline cognitive function.</td>
</tr>
<tr>
<td><strong>Evaluation of Outcomes:</strong> Is patient’s circulatory status within normal limits? Does patient have reactive pupils and baseline cognitive function intact?</td>
</tr>
<tr>
<td><strong>Intervention</strong> Monitor circulation, movement, and sensation to extremities every 1 to 4 hours. <strong>Rationale</strong> Early detection of spasm or reocclusion minimizes risk of ischemia and necrosis. <strong>Evaluation</strong> Does graft or vessel remain patent?</td>
</tr>
<tr>
<td><strong>Intervention</strong> Mark location of pulses on affected extremity. <strong>Rationale</strong> Allows for quick location of pulses. <strong>Evaluation</strong> Are pulses located easily?</td>
</tr>
<tr>
<td><strong>Intervention</strong> Perform neurologic checks every 2 to 4 hours (carotid). <strong>Rationale</strong> Allows early detection of complications. <strong>Evaluation</strong> Are major neurologic or circulatory problems detected?</td>
</tr>
</tbody>
</table>
when veins rupture, releasing RBCs into the tissues; the RBCs then break down and stain the tissue brown. Stasis ulcers develop from the increased pressure and rupture of small veins. Signs of skin breakdown are most commonly seen at the medial malleolus of the ankle. Stasis ulcers are a serious complication of venous insufficiency that are difficult to cure and can affect the patient’s quality of life.

**THERAPEUTIC MEASURES.**

The focus of treatment is to decrease edema and heal skin ulcerations. Compression wraps such as elastic stockings or bandage wraps are necessary to decrease edema. Bed rest and elevation of legs and feet above the heart are important to assist with drainage of lower extremities. Patients are advised not to keep legs dependent and to avoid long periods of standing or sitting to prevent increased pressure and pain. The foot of the bed should be elevated 5 to 6 inches. Additionally, patients should be encouraged to exercise and walk often during nonacute episodes. Patients should be taught not to cross their legs or wear constrictive clothing that would decrease venous blood return to the heart.

Skin ulcers are usually cultured and treated with topical antibiotics if needed. Wound care can be chronic and challenging (see Chapter 54). An Unna boot, which is a gauge dressing coated with zinc oxide, calamine, and glycerin, may be used to promote healing in se vere ulcers. Zinc promotes wound healing and can be soothing. The Unna boot is applied snugly and provides compression therapy as well. It is changed every 2 to 7 days. Skin grafting may be necessary if ulcerations are severe or do not heal.

Patient-coping skills are assessed to determine patient’s ability to cope with chronic ulcers that may affect quality of life. Baseline knowledge of contributing factors for venous disorders is determined for teaching plans.

**Nursing Diagnoses, Planning, and Implementation.**

**Acute Pain related to edema and increased pressure**

**EXPECTED OUTCOME:** The patient will report pain is at a tolerable level within 30 minutes of report of pain.

- Use rating scale such as 0 to 10 to identify pain level to provide consistency in pain reporting.
- Elevate legs above heart level (such as in a reclining chair) and avoid long periods of standing to reduce pooling of fluid.
- Apply compression therapy as ordered to promote drainage and reduce edema.
- Administer analgesics as prescribed to provide pain relief.

**Impaired Tissue Integrity related to chronic venous congestion**

**EXPECTED OUTCOME:** The patient will have intact tissue integrity.

- Assess and document size, shape, and depth of wound to evaluate healing of wound over time.
- Provide a comprehensive plan for wound care including methods of pressure relief from edema, treatments, and nutrition as ordered to ensure that quality wound care is provided.
- Provide wound care as ordered to aid in wound healing.

**Ineffective Health Maintenance related to deficient knowledge of venous disease**

**EXPECTED OUTCOME:** The patient will report understanding and management of his or her venous disorder.

- Assess the patient’s present understanding of the disease to determine baseline knowledge.
• Explain to patient how to control risk factors and prevention of varicose veins: weight reduction, elevation of the extremities, walking, and exercise help increase muscle strength and contraction.
• Explain that tight-fitting clothes at tops of legs or waist should not be worn to prevent venous occlusion.
• Encourage patient with varicose veins to wear support hose to assist blood flow return to the heart.
• Explain need to avoid heating devices because of decreased sensitivity and risk of burns.
• Encourage questions and allow the patient the opportunity to verbalize new information and skills to enhance learning.
• Document teaching and evaluation of patient knowledge to communicate patient progress toward goal attainment.

See also the “Nursing Care Plan for the Patient After Vascular Surgery.”

Evaluation. Interventions are successful if the patient reports understanding of venous disease and prevention and that pain is at an acceptable level.

Vascular Surgery
Vascular impairments requiring surgery may be acute or chronic and involve arteries, veins, or lymphatic vessels. When intermittent claudication becomes severe or disabling or when the limb is at risk for amputation, then surgical vascular grafting may be done.

Nursing Process for the Patient Undergoing Preoperative Vascular Surgery

DATA COLLECTION. A baseline assessment is important for postoperative comparison and discharge planning. Pain control needs and circulatory status are assessed. Diagnostic test results (CBC, electrolytes, PT, PTT, and bleeding time) are reviewed and typing and crossmatching of blood to be placed on hold is performed.

NURSING DIAGNOSES. The nursing diagnoses for preoperative vascular surgery may include the following:
• Acute or Chronic Pain related to ischemia of tissue distal to occlusion or aneurysm
• Anxiety related to unknown outcome, pain, powerlessness, or threat of death
• Deficient Knowledge, preoperative and postoperative procedures, related to unfamiliar process

See Chapter 12 for further preoperative nursing process information.

Embolectomy and Thrombectomy
When an artery becomes completely occluded by an embolus or thrombus, it is considered a surgical emergency. Emergency embolectomy is the procedure of choice only if the affected extremity is viable. Surgical removal to restore blood flow and oxygenation to the tissue distal to the occlusion is imperative to decrease ischemia and necrosis.

Vascular Bypasses and Grafts
Vascular bypass surgery involves the use of either autografts, such as the patient’s own saphenous vein, or a synthetic graft material. The graft is anastomosed to the artery proximal to the occlusion and tunneled past the occlusion, where the distal end of the graft is anastomosed to the artery (Fig. 24.10). The graft is assessed for hemostasis and function, and then the wound is sutured closed.

Endarterectomy
Arteriosclerotic plaques are dissected from the lining of the arterial wall and removed in a procedure called an endarterectomy. This is most commonly performed on the carotid artery but may be done on peripheral arterial vessels as well. To control blood flow, the artery is clamped on both sides of the occlusion, and an incision is made into the artery. The plaque within the artery is removed with forceps. The artery is irrigated to remove any further debris and then closed with sutures. The clamps are removed, and the skin incision is closed. A drain may be placed to help prevent hematoma formation.

WORD BUILDING
Endarterectomy: end—inside + arter—artery + ectomy—excision
Angioplasty

Minimally invasive techniques can also be used to open plaque-blocked arteries. These techniques include balloon or laser angioplasty. A flexible laser-tipped catheter is inserted into an artery and advanced to the site of the blockage. The laser sends out pulsating beams of light, which vaporize the plaque. This procedure is used for patients with smaller occlusions in the distal superficial femoral, proximal popliteal, and common iliac arteries.

Stents

Stents are placed inside an artery to provide support to the artery walls and keep them open. Stents are placed in a procedure similar to PCI discussed earlier. Stents may also be used in combination with other procedures such as angioplasty.

Complications of Vascular Surgery

Bleeding and hemorrhage can occur with all vascular surgeries. Drainage can be expected with most surgeries. Drainage is usually small when peripheral vessels are involved. But with involvement of the great vessels, drainage is usually heavier and drains are often placed to prevent swelling and hematoma formation. If hemorrhage occurs, manual pressure is applied to the site of bleeding, and the HCP is notified immediately. Extensive surgeries may also result in significant blood loss, leading to fluid volume deficit or shock.

Reocclusion is possible with any vascular surgery. If thrombi or emboli develop and block blood flow, a surgical emergency results. Loss of a pedal pulse may signify reocclusion and must be immediately reported to the HCP. Blood flow needs to be reestablished within 4 to 6 hours to prevent risk of amputation of that extremity.

Nursing Process for the Patient After Vascular Surgery

DATA COLLECTION. Upon transfer postoperatively to either the ICU or surgical unit, the patient is positioned comfortably and a head-to-toe assessment is performed and documented. Abnormal findings are reported to the HCP. A patent airway is ensured and vital signs are monitored. The patient’s pain level is rated on a scale of 0 to 10. All IVs and drains are monitored. Measurement of input and output (I&O) is done hourly, then every 4 to 8 hours. CBC, INR, PTT, and electrolytes are monitored. Increasing abdominal girth measurements (for AAA repair) can indicate hemorrhage. Any abnormal change is reported immediately to the HCP.

Initially, neurovascular checks are ordered every 15 minutes for the first 2 hours, then every 30 minutes for 1 to 3 hours, then hourly for aortic or extremity vascular surgery. Neurovascular checks include extremity movement and sensation, presence of numbness or tingling, pulses, temperature, color, and capillary refill (less than 3 seconds normally). Peripheral pulses are palpated, or assessed with Doppler ultrasound if not palpable, marked, and compared with the unaffected extremity to detect deficits. If a pulse is absent or weak or the extremity is cool or dusky, the HCP is notified immediately. A return to surgery for an embolectomy or other procedure is anticipated.

CRITICAL THINKING

Mr. Janeway

1. What four priority areas of data collection should the nurse focus on for Mr. Janeway?
2. What other information might the nurse want to know regarding Mr. Janeway’s medical history?
3. List three priority nursing diagnoses for Mr. Janeway.
4. State one outcome for each nursing diagnosis.
5. What nursing interventions are appropriate for each nursing diagnosis identified?

Suggested answers are at the end of the chapter.

NURSING CARE TIP

Neurovascular checks refer to the assessment of an extremity. (Neurologic checks refer to assessment of the central nervous system.) The following are areas to examine on an extremity when doing neurovascular checks. They are identified under the category for which they provide information:

NEUROLOGIC VASCULAR
Movement Pulses
Sensation Capillary refill
Numbness Color (nailbed or skin)
Tingling Temperature

LYMPHATIC SYSTEM

The lymphatic system returns fluid from other tissues in the body to the bloodstream. It is a pumpless system with
one-way valves that return the fluid to the heart. Any interruption in the flow of lymph results in edema.

**Lymphangitis**

*Lymphangitis* is a bacterial infection of the lymphatic channels. The infection can occur in the arms or legs and is commonly caused by *Staphylococcus* or *Streptococcus* bacteria. It is a serious infection that can cause sepsis and be fatal. Symptoms include painful red streaks in the extremity. Fever and chills may be present. Lymph nodes in the area of infection can be enlarged and painful. Therapy is initiated with a broad-spectrum antibiotic as the drug of choice. The use of heat on the extremity, as well as elevating it, can help improve circulation. The use of a pneumatic pressure device can be ordered to help alleviate congestion.

**Nursing Process for the Patient With Lymphangitis**

**DATA COLLECTION.** Frequent monitoring of the affected area for edema and skin breakdown is needed to prevent complications from edema. The nurse monitors the size of the extremity and notifies the HCP of any increase in size or possible spread of infection. Pain level and fever are monitored.

**NURSING DIAGNOSES, PLANNING, AND IMPLEMENTATION.**

**Acute Pain related to tissue damage and edema from infection**

**EXPECTED OUTCOME:** The patient will report an absence or acceptable level of pain within 30 minutes of reporting pain.

- Explain and have patient use pain rating to report pain level for consistency.
- Administer analgesics as prescribed to provide pain relief.
- Recheck pain level 30 to 60 minutes after analgesic given to determine if pain relief has been obtained.
- Position extremity for comfort and elevate to reduce edema, which can cause pressure and pain.

**Risk for Excess Fluid Volume related to congested lymph nodes from infection**

**EXPECTED OUTCOME:** The patient will exhibit no evidence of edema.

- Apply heat on the extremity as ordered to increase circulation and reduce edema.
- Elevate extremity to help improve circulation and prevent edema.

**EVALUATION.** Interventions are successful if the patient reports pain is at an acceptable level and no edema is present.

---

**CRITICAL THINKING**

**Mr. Jones**

1. Irregular, respiratory rate 28 per minute and shallow, lung sounds diminished with crackles in bilateral bases.
2. Pain control, coughing and deep breathing, and incentive spirometer.
4. Hemorrhage, reduced cardiac output.
5. HCP for orders, pharmacist for medication orders, respiratory therapist for pulmonary concerns.

**Mrs. Sims**

1. Place on bedrest, administer oxygen via nasal cannula at 2 L/min, assess blood pressure and pulse, administer NTG sublingual as ordered, obtain ECG, and notify HCP.
2. She may be having an anginal attack versus acute MI.
3. NTG usually stops chest pain associated with angina. Rest may also alleviate chest pain. Neither NTG nor rest will relieve the pain of an acute MI.
4. Indicators of an MI include patient history, ECG changes with ST-segment elevation, elevated troponin I, and CK-MB elevation.

**Mrs. May**

1. Monitor the patient’s left leg for color, temperature, capillary refill, and pulses: femoral, popliteal, dorsalis pedis, and posterior tibial. Compare findings with findings in the right leg.
2. If unable to palpate pulses, use a Doppler ultrasound that enhances sound to locate pulses.
3. The patient’s symptoms could be caused by an embolism above left femoral artery.
4. To document finding, you would obtain more assessment data. A sample of SOAP charting for your additional findings is given:
   - **S:** “I have a severe pain in my left groin that just started. It is at 9 on a scale of 0 to 10.”
   - **O:** Grimacing, moaning, and holding left upper leg. Left leg cool, color pale, nailbeds pale, capillary refill 10 seconds, unable to palpate pulses. Faint femoral and popliteal pulse, no dorsalis pedis or
posterior tibial pulse heard with Doppler. Right leg warm, pink, capillary refill 3 seconds, with all pulses palpable.

**A:** Ineffective tissue perfusion.

**P:** Notify HCP stat.

5. Immediate interventions include complete bedrest, protecting the leg, and notifying the HCP.

6. Medical interventions could include medication for pain and use of an anticoagulant, such as heparin. If no pulses are present, a thrombolytic agent may be ordered. Surgery is possible.

7. Thrombectomy or embolectomy may be necessary to save the limb.

**Mr. Janeway**

1. Priority areas for data collection include respiratory status, circulatory status of right leg and foot, vital signs, and pain level.

2. A medical history should include Mr. Janeway’s usual blood sugar values, insulin dose, ambulation aids, gait, knowledge base regarding his various disease processes, and what led to this hospitalization.

3. Priority nursing diagnoses include (1) Pain related to surgery of right lower leg; (2) Ineffective Tissue Perfusion related to embolectomy of right lower leg, renal insufficiency; and (3) Risk for Injury related to leg surgery, diabetes, obesity.

4. Outcomes include (1) verbalizes relief of pain; (2) maintains adequate tissue perfusion as evidenced by palpable peripheral (pedal) pulses, warm and dry skin; and (3) remains free from injury.

5. Nursing interventions include the following: (1) position (especially right leg) for comfort; keep the right leg slightly elevated; educate the patient regarding the need to ask for pain medication before pain is too severe; educate the patient regarding the need to take pain medication to minimize the negative physiological effects of pain; monitor pain on a pain scale; evaluate the effectiveness of medication using the same pain scale; report ineffective pain measures. (2) Check pedal pulses, surgical dressing, pedal sensation and movement, and color, initially and every hour; report changes; check capillary refill; monitor for pain in extremities; monitor for edema in extremities; keep leg elevated slightly. (3) Make sure the nursing call light is within reach; provide assistance with ambulation; use walking aids.

**REVIEW QUESTIONS**

1. The nurse would evaluate the patient as understanding teaching on prevention of coronary artery disease if the patient stated that which of the following is a risk factor for coronary artery disease that can be controlled?
   1. Family history of cardiovascular disease
   2. Hypertension
   3. Ethnicity
   4. Family history of diabetes mellitus

2. The nurse is assisting with collecting data on a female patient in the emergency department. Which of these findings during data collection does the nurse report to the registered nurse as a possible atypical symptom of a myocardial infarction in the absence of chest pain?
   1. Fatigue
   2. Dizziness
   3. Sweating
   4. Nausea

3. The nurse would evaluate the patient as understanding teaching on the purpose of coronary artery bypass graft surgery if the patient made which of the following statements?
   1. “It cures coronary artery disease.”
   2. “It is done to increase blood flow to the myocardium.”
   3. “It prevents spasms of the coronary arteries.”
   4. “It will decrease blood flow to the coronary arteries.”
UNIT FIVE
Understanding the Cardiovascular System

4. The nurse is reinforcing teaching for a patient prescribed sublingual nitroglycerin tablets. The nurse should instruct the patient to use this medication in which of the following ways?
   1. Take one tablet and lie down for 1 hour and repeat if pain unrelieved.
   2. Place two tablets under the tongue daily to prevent angina.
   3. Swallow one tablet, wait 10 minutes, swallow two tablets if pain persists, swallow 3 tablets if pain remains after 15 minutes.
   4. With symptoms of MI, place one tablet under the tongue and if after 5 minutes the pain is not relieved, call 911.

5. The nurse would evaluate the patient as understanding teaching on peripheral arterial occlusive disease if the patient stated that which of the following is the classic symptom?
   1. Angina
   2. Edema
   3. Intermittent claudication
   4. Stasis ulcers

6. Which of the following medications is used to treat intermittent claudication?
   1. Cholestyramine (Questran)
   2. Enoxaparin (Lovenox)
   3. Pentoxifylline (Trental)
   4. Ranolazine (Ranexa)

7. The nurse is caring for a patient who has peripheral arterial disease. Which of the following statements by the patient indicates understanding of how to manage the pain of peripheral arterial disease?
   1. “I will lie down frequently.”
   2. “I will use a reclining chair.”
   3. “I will sit with my legs down.”
   4. “I will do knee flexion exercises.”

Answers can be found in Appendix C.

Nursing Care of Patients With Cardiac Dysrhythmias

Linda S. Williams

Learning Outcomes

1. Describe how electrical activity flows through the heart.
2. List the six steps used for dysrhythmia interpretation.
3. Explain current medical treatments for each type of cardiac dysrhythmias.
4. Identify types of cardiac pacemakers and implantable cardioverter defibrillators and their uses.
5. Plan nursing care for patients with a dysrhythmia.
6. Plan nursing care for patients with an implanted device.

Key Terms

- ablation (uh-BLAY-shun)
- atrial depolarization (AE-tree-uhl DEE-poh-lur-ih-ZAY-shun)
- atrial systole (AE-tree-uhl SISS-tuh-lee)
- atrioventricular node (AE-tree-oh-ven-TRICK-yoo-lur NOHD)
- bigeminy (bye-JEM-ih-nee)
- bradycardia (BRAY-dih-KAR-dee-yah)
- bundle of His (BUN-duhl of HISS)
- cardioversion (KAR-dee-oh-VER-zhun)
- defibrillation (dee-FIB-ri-lay-shun)
- dysrhythmia (dis-RITH-mee-yah)
- electrocardiogram (ee-LECK-troh-KAR-dee-oh-GRAM)
- fluoroscopy (fluh-RAHS-kuh-pee)
- hyperkalemia (HIGH-per-kuh-LEE-mee-ah)
- hypomagnesemia (HIGH-poh-MAG-nuh-ZEE-mee-ah)
- isoelectric line (EYE-so-e-LECK-trick LINE)
- multifocal (MUHL-ti-FOH-cull)
- sinoatrial node (SIGH-noh-AY-tree-ahl NOHD)
- trigeminy (trig-JEM-i-nee)
- unifocal (YOO-ni-FOH-cull)
- ventricular diastole (ven-TRICK-yoo-lar dye-AS-tuh-lee)
- ventricular repolarization (ven-TRICK-yoo-lar RE-pol-lahr-ih-ZAY-shun)
- ventricular systole (ven-TRICK-yoo-lar SIS-tuh-lee)
- ventricular tachycardia (ven-TRICK-yoo-lar TACK-ee-KAR-dee-yah)
The heart’s electrical conduction system initiates an impulse whose purpose is to stimulate the mechanical cells of the heart to contract (Fig. 25.1). Electrical activity can be viewed on a cardiac monitor or recorded on an electrocardiogram (ECG) tracing. The activity seen on an ECG does not necessarily mean that the mechanical cells of the heart have contracted in response to the electrical impulse. So how can you verify heart muscle contraction and subsequent pumping of blood? By assessing the patient’s blood pressure and apical and peripheral pulses, you will have evidence to determine if cardiac contraction occurred.

Do you recall what area of the conduction system is referred to as the normal pacemaker of the heart? Located in the upper posterior wall of the right atrium is the sinoatrial (SA) node. The SA node is the primary pacemaker of the heart because its inherent (built-in) rate is faster than those of the other conduction sites in the atrioventricular (AV) node or ventricles. It normally fires at a rate of 60 to 100 beats per minute (bpm). As a protective mechanism if the SA node slows or fails, other areas of the heart can initiate impulses to keep the heart beating. This mechanism is referred to as escape. The AV node has an inherent rate of 40 to 60 bpm. The body can usually function adequately with this rate. If the AV node is unable to initiate an impulse, then the ventricles can take over at 20 to 40 bpm. However, the ventricular rate of 20 to 40 bpm is not adequate to meet the body’s oxygen needs, so the patient begins to show signs of inadequate cardiac output such as dyspnea, abnormal vital signs, and changes in level of consciousness. Treatment is usually needed to reestablish a normal heart rate as soon as possible.

After the SA node fires, the impulse spreads through the atria conduction system to the AV node, stimulating the atria to contract. This is known as atrial systole. The atrial contraction propels blood out of the atria and into the relaxed ventricles during ventricular diastole. At the AV node, the impulse is briefly delayed. Next the impulse travels down the bundle of His, which divides into right and left bundle branches through the Purkinje fibers. This stimulates both ventricles to contract upward from the apex of the heart, pushing blood to ward the arteries. This contraction is known as ventricular systole.

Cardiac Cycle

A cardiac cycle is the period from the beginning of one heartbeat to the beginning of the next. The cardiac cycle is the electrical representation of the impulse that stimulates contraction and relaxation of the atria and ventricles. Within the normal cardiac cycle, there is a P wave, a QRS complex, and a T wave (Fig. 25.2).

ELECTROCARDIOGRAM

The electrical activity of the heart is seen either with an ECG that shows the activity for that moment when the ECG is obtained or with continuous cardiac monitoring. Electrodes placed on the patient’s skin allow various views of the heart’s electrical activity to be seen. Each view of the heart is referred to as a lead. A 12-lead ECG provides 12 different views of the heart’s electrical activity, whereas an 18-lead ECG shows 18 views. For continuous monitoring of cardiac electrical activity, one lead providing a good view may be used, although
with a five-electrode system, two views can be displayed at the same time. Continuous 12-lead monitoring can also be done.

Specialized training, usually obtained by physicians, is required to interpret ECGs for normal and abnormal heart rhythms. By learning the characteristics of a normal heart rhythm and rules for common dysrhythmias, you will be able to report rhythm changes to your supervisor or the health care provider (HCP).

**LEARNING TIP**

Think of a 12- or 18-lead ECG as if you had a camera that you were using to take pictures (views) of an object such as an apple. To obtain views that showed you all of the areas of the apple—front, side, back, side—you would take a picture and then move the camera a little to get the view next to the one you had just taken. You would continue moving the camera until you had worked your way around the entire apple. This would then give you a view of the entire apple. This is what a 12- or 18-lead ECG does to allow viewing of the entire conduction system of the heart.

**Components of a Cardiac Cycle**

**P Wave**

The P wave is the first wave of the cardiac cycle and represents atrial depolarization. When the SA node fires, the electrical impulse spreads from the right to left atrium. The normal P wave appears rounded. When compared with other waveforms, it looks like a small hill. Disorders that change atrial size cause alterations in P-wave shape and size.

**Electrocardiogram Graph Paper**

The intervals of each of the components of a cardiac cycle can be measured in seconds of time on the ECG graph paper on which the heart rhythm is recorded. The graph paper is calibrated in a grid with small squares divided into heavy lined blocks of 25, five squares wide and five squares high (Fig. 25.3). Each small square is 0.04 seconds wide. There are five small squares, which equal 0.20 seconds of time, horizontally between two heavy vertical black lines (see Fig. 25.3). You will measure the waveforms horizontally from left to right on the graph paper. The height of waveforms (amplitude) is measured vertically.

You have probably seen a heart monitor, perhaps on television, with a straight line displayed on it. This straight line, called the isoelectric line (baseline), occurs when there is no electrical current, or the positive and negative electrical activity is equal. The isoelectric line is seen when there are no positive or negative electrical wave deflections. When cardiac cycle electrical impulses (seen as waveforms) occur, they are either upward (positive) or downward (negative) from the isoelectric line.

**Learning Tip**

To make measuring waves easier:
- Identify the isoelectric line as you measure waveform tracings to help you determine the presence and type of wave. Place a straight edge along the isoelectric line so that it lays below this line, to then see any positive waves above the line; then lay the straight edge above the line to see any waves that fall below the line.
- If possible, find a wave that begins on a line to make it visually easier to see the interval being measured (Fig. 25.4).
- If the wave starts or ends in the middle of a small square, count it as one-half of a square, which is 0.02 seconds. Do not go smaller than one-half of a square.

**PR Interval**

The PR interval (PRI) represents the time it takes the electrical impulse to travel from the SA node to the AV node. The PRI starts at the beginning of the P wave and ends at the beginning of the QRS complex. Counting the number of small squares horizontally that the interval covers and then multiplying by 0.04 determines the length of the PRI (see Fig. 25.4). The normal PRI is 0.12 to 0.20 seconds (three to five small squares).
QRS Complex

The QRS complex represents ventricular depolarization and is composed of three waves: Q, R, and S. The Q wave is the first downward deflection after the P wave. The R wave is the first upward deflection after the P wave. The S wave is the first negative deflection after the R wave (see Fig. 25.2). The S wave ends when it returns to the isoelectric line (this is why locating the isoelectric line is helpful when first learning to identify waves). It is important to note that all three waves are not always present in every QRS complex. Even with absent waves, the QRS is still referred to as the QRS complex and can be considered normal (Fig. 25.5). The QRS complex is larger than the P wave because the ventricles have more muscle mass, so it looks like a mountain compared with the size of other waveforms.

QRS Interval

The QRS interval represents the time it takes for the electrical impulse to travel from the AV node rapidly through the ventricles. To measure the QRS interval, count the number of squares from the wave that starts the QRS complex to the end of the wave that completes the QRS complex. For example, when a Q, R, and S are present, measure from the beginning of the Q wave to the end of the S wave (Fig. 25.6). If there is an R and an S present, measure from the beginning of the R to the end of the S. But if there is only an R present, measure from the beginning of the R to the end of the R. The normal QRS interval is 0.06 to 0.10 seconds (1.5–2.5 boxes).

T Wave

The T wave represents ventricular repolarization, the resting state of the heart, when the ventricles are filling with blood and preparing to receive the next impulse. It is a nicely rounded wave, and, in our size comparisons of other waves, it is a medium-size hill. In most leads, the T wave is an upward (positive) deflection, after the QRS complex, and ends with a return to the isoelectric line. An inverted (downward) T wave can indicate coronary ischemia (Fig. 25.7).

QT Interval

The QT interval measures the time from the start of the Q wave to the end of the T wave (see Fig. 25.2). This represents the time for ventricular depolarization and...
repolarization. Normal ranges, 0.34 to 0.43 seconds, vary based on gender, heart rate, and age (a QT chart for identifying normal values is used). Prolonged or shortened QT intervals can lead to ventricular dysrhythmias. Abnormal intervals may be due to genetic causes, heart conditions, electrolyte imbalances, or medications that can prolong the QT interval.

U Wave
The U wave is small and often not seen. It occurs shortly after the T wave. It is most prominent in patients with hypokalemia (low serum potassium level; Fig. 25.8).

ST Segment
The ST segment reflects the time from completion of a contraction (depolarization) to recovery (repolarization) of myocardial muscle for the next impulse. The ST segment starts at the end of the QRS and ends at the beginning of the T wave (Fig. 25.9A). The ST segment is examined when patients experience chest pain. If a patient has nontransmural ischemia, the ST segment can become inverted or depressed (Fig. 25.9B). With transmural ischemia, the ST segment can elevate from the isoelectric line (Fig. 25.9C).

**INTERPRETATION OF CARDIAC RHYTHMS**

**Six-Step Process for Dysrhythmia Interpretation**

An orderly, systematic method for interpreting ECG rhythms should be used to increase understanding of items to examine and ensure nothing is overlooked. Six steps are examined in this process (Table 25.1). Use the findings of the first five steps to identify the ECG rhythm according to the five rules for each dysrhythmia. Then measure the QT interval so that abnormalities can be reported to the HCP. A 6-second ECG tracing is used when interpreting rhythms (see Fig. 25.3).

**Step 1. Regularity of the Rhythm**

The regularity of the rhythm can be determined by looking at the R-to-R spacing on the ECG (Fig. 25.10). The same spacing between each R to R, with a rare variation of no greater than two small squares, is seen in a normal rhythm. To determine the regularity of a rhythm, count the number of small squares between each R wave, which normally should remain the same, or use a caliper (two-sided, movable metal instrument with sharp points) to measure the R-to-R spacing.

To use a caliper for measuring R waves, one point is placed on an R wave, and the other point is placed in the same spot on the next R wave. Then, without changing the distance between the caliper points, move the caliper from R wave to R wave across the ECG tracing (also known as an ECG strip) to see if R waves are regularly spaced. If the distance is the same, the rhythm is regular. If the distance varies, the rhythm is irregular. This can be further described by these fun terms: an irregular rhythm can be regularly irregular, which means it has a predictable pattern of irregularity, or irregularly irregular, without any pattern of irregularity.
Step 2. Heart Rate

After rhythm regularity is determined, a 1-minute heart rate is calculated. One of the two following methods is used:

1. Count the number of small (0.04-second) squares between two R waves and divide that number into 1500. This gives the beats per minute, because 1500 small squares equals 1 minute (Fig. 25.11). This method is used only for regular rhythms and is very accurate. A rate meter is a visual paper copy of this mathematical calculation for an entire 6-second ECG tracing that the nurse can view to calculate the 1-minute heart rate. It is readily available in locations where these calculations are routinely done.

2. Six-second method: the 6-second method is used for irregular rhythms. It may also be used when a rapid estimate of a regular rhythm is needed, although it is not the most accurate method for regular rhythms. At the top of ECG graph paper are vertical marks at 3-second intervals (see Fig. 25.3). Count the number of R waves in a 6-second strip (three vertical marks) and multiply the total by 10 (the number of 6-second time periods in a minute) to obtain the beats per minute (6 seconds × 10 = 60 seconds or 1 minute; Fig. 25.12).

Step 3. P Waves

The P waves on the ECG tracing are examined to see if (1) there is one P wave in front of every QRS, (2) the P waves are regularly occurring, and (3) the P waves all look alike (see Fig. 25.10). If all of the P waves meet these criteria, they are considered normal. If they do not, further examination of the tracing is necessary to determine the dysrhythmia.

Step 4. PR Interval

All PR intervals are measured to determine whether they are normal (0.12–0.20 seconds) and constant. If the PRI is found...
to vary, it is important to note whether there is a pattern to the variation.

**Step 5. QRS Interval**
The QRS intervals are measured to determine whether they are all within normal range (0.06–0.10 seconds). Abnormal QRS complexes require further examination.

**Step 6. QT Interval**
Finally, the QT interval is measured to ensure that it is not shortened or prolonged, which can lead to dysrhythmias. Abnormal QT intervals should be reported to the HCP.

---

**NORMAL SINUS RHYTHM**

**Description**
Normal sinus rhythm (NSR) is the heart’s normal rhythm (Fig. 25.13). It originates in the SA node and has complete, regular cardiac cycles at 60 to 100 bpm.

**NORMAL SINUS RHYTHM RULES**
1. Rhythm: regular
2. Heart rate: 60 to 100 bpm
3. P waves: rounded, upright, precede each QRS complex, alike
4. PR interval: 0.12 to 0.20 seconds
5. QRS interval: less than or equal to 0.10 seconds.

---

**DYSRHYTHMIAS**

Two terms are used for rhythm disturbances: *arrhythmia* (irregularity or loss of rhythm of the heartbeat) and *dysrhythmia* (abnormal, disordered, or disturbed rhythm). These two terms are used interchangeably, but *dysrhythmia* is the most accurate term for the discussion of most abnormal rhythms.

Several mechanisms can cause a dysrhythmia. Examples of these mechanisms are a disturbance in the formation of an impulse and a disturbance in the conduction of the impulse. When impulse formation is disturbed, the impulse may arise from the atria, the AV node, or the ventricles rather than the SA node. This disturbance can be seen as an increased or decreased heart rate, early or late beats, or atrial or ventricular fibrillation. With a disturbance in conduction, there may be normal formation of the impulse, but it becomes blocked within the electrical conduction system, resulting in abnormal conduction (as in heart block or bundle branch blocks). See www.heart.org for American Heart Association Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care Science.

**Dysrhythmias Originating in the Sinoatrial Node**
Rhythms arising from the SA node are referred to as *sinus rhythms*. Disturbances in conduction from the SA node can cause irregular rhythms or abnormal heart rates. Dysrhythmias arising from the SA node are rarely dangerous. Patients, especially those with heart, lung, or kidney disease, who cannot tolerate a rapid or slow heart rate, can require treatment.

---

**Sinus Bradycardia**
**Bradycardia** is a rate slower than 60 bpm that can be asymptomatic or symptomatic (usually below 50 bpm). Sinus bradycardia has the same cardiac cycle components as NSR. The only difference between the two is a slower rate caused by fewer impulses originating from the SA node (Fig. 25.14).

Do you see that the term *sinus bradycardia* tells you this difference? The name says the impulse is coming from the sinus node (sinus) but at a slower rate than normal (bradycardia). See, it is easy to understand what is happening in the dysrhythmia when you look at what the name is telling you.

---

**LEARNING TIP**
The origin and the type of a problem are used to name a dysrhythmia. Let’s name a slow dysrhythmia that originates in the sinoatrial node. The origin is sinus and the type of problem (slow rate) is bradycardia = sinus bradycardia. The term normal is not used because there is a problem. So what would a fast dysrhythmia originating in the SA node be called? Yes! Sinus tachycardia.
ETIOLOGY. Medications such as digoxin (Lanoxin) as well as myocardial infarction (MI) and electrolyte imbalances can cause bradycardia. Well-conditioned athletes can also have slower heart rates because their hearts work efficiently.

SINUS BRADYCARDIA RULES.
1. Rhythm: regular
2. Heart rate: less than 60 bpm
3. P waves: smoothly rounded, precede each QRS complex, alike
4. PR interval: 0.12 to 0.20 seconds
5. QRS interval: less than or equal to 0.10 seconds.

SIGNS AND SYMPTOMS. With symptomatic bradycardia decreased BP, respiratory distress, diminished or absent peripheral pulses, fatigue, or syncope can occur.

THERAPEUTIC MEASURES. Asymptomatic bradycardia does not require treatment. Observe the patient for symptom development, while the underlying cause is identified for correction. For the symptomatic patient, treatment is begun as the cause is corrected. Treatment can include intravenous (IV) atropine, or infusions of dopamine or epinephrine or transcutaneous pacing if atropine is ineffective (Table 25.2). Transvenous pacing can be considered, if needed.

Sinus Tachycardia
Tachycardia is defined as a heart rate greater than 100 bpm that originates from the SA node. Sinus tachycardia has the same components as NSR except the rate is faster (Fig. 25.15).

ETIOLOGY. Sinus tachycardia causes include physical activity; hemorrhage; shock; medications such as epinephrine, atropine, or nitrates; dehydration; fever; MI; electrolyte imbalance; fear; and anxiety. Tachycardia occurs as a compensatory mechanism for hypoxia when additional cardiac output is needed to deliver oxygen to tissues.

SINUS TACHYCARDIA RULES.
1. Rhythm: regular
2. Heart rate: 101 to 180 bpm
3. P waves: rounded, precede each QRS complex, alike
4. PR interval: 0.12 to 0.20 seconds
5. QRS interval: less than or equal to 0.10 seconds.

| **Beta Blockers** | atenolol (Tenormin), metoprolol succinate (Lopressor, Toprol XL) | Check apical pulse and BP before giving. If pulse <60 bpm, BP less than 100 mm Hg systolic, notify HCP. Instruct patient to rise slowly and not stop drug abruptly. |
| Decrease myocardial contractility. |
| Controls rate in sinus tachycardia, PAC, atrial flutter, atrial fibrillation, PVC. |

| **Calcium Channel Blocker** | amlodipine (Norvasc) | Assess apical pulse and blood pressure. If BP <90 mm Hg systolic or apical rate less than 60 bpm, notify HCP. Administer before meals and at bedtime. |
| Decreases myocardial contractility and depresses conduction system. |
| Controls rate in sinus tachycardia, atrial flutter, and atrial fibrillation. |

| **Inotrope—Cardiac Glycoside (Positive Inotrope and Negative Chronotrope)** | Digoxin (Lanoxicaps, Lanoxin) | Take apical pulse for 1 minute; if less than 60 bpm, notify HCP. Therapeutic digoxin levels: 0.5–2 mg/mL. Monitor drug level and electrolytes (hypokalemia, hypomagnesemia, hypercalcemia increase toxicity). |
| Slows heart rate. |
| Maintains sinus rhythm for sinus tachycardia, atrial flutter, atrial fibrillation. |

| **Vasopressors** | epinephrine (Adrenalin) | Contraindicated with nonselective beta blockers. |
| Cardiac stimulation, vasoconstriction, bronchodilation. |
| Treats asystole, ventricular tachycardia, ventricular fibrillation, symptomatic bradycardia. |

| **Vasoconstricts. Reduces urine volume. Single dose may replace dose of epinephrine.** | vasopressin (Pitressin) | Avoid IV site extravasation because of risk of necrosis and gangrene. |
| Treats pulseless ventricular tachycardia, ventricular fibrillation, asystole. |

| Increases cardiac output and blood pressure. Treats bradycardia. | dopamine | Monitor blood pressure. |

---

**Note.** INR = international normalized ratio; PAC = premature atrial contraction; PVC = premature ventricular contractions.

**SIGNS AND SYMPTOMS.** Sinus tachycardia can be asymptomatic. But if the rate is very rapid (usually >150 bpm) and sustained for long periods, the patient may experience angina, dyspnea, syncope, or tachypnea. Older patients can become symptomatic more rapidly than younger patients (“Gerontological Issues—Dysrhythmia Risk”). Patients with MI might not tolerate a rapid heart rate and have more severe symptoms because cardiac workload is increased.
Dysrhythmias Originating in the Atria
As previously discussed, all areas of the heart can initiate an impulse. The SA node is the primary pacemaker, but if the atria initiate impulses faster than the SA node, they become the primary pacemaker. Atrial rhythms are usually faster than 100 bpm and can exceed 200 bpm. When an impulse originates outside the SA node, the P waves produced look different (flatter, notched, or peaked) from the rounded P waves from the SA node. This indicates that the SA node is not controlling the heart rate. These atrial impulses travel to the ventricles to initiate a normal QRS complex after each P wave.

Gerontological Issues

Dysrhythmia Risk
Factors that increase the risk of dysrhythmias in older adults include the following:
- Digitalis toxicity (most common)
- Hypokalemia
- Acute infection
- Hemorrhage
- Angina
- Coronary insufficiency or cardiomyopathy (exercise, stress)
- Thickness of the heart tissue
- Sleep apnea
- Hypothyroidism or hyperthyroidism.

Dysrhythmias that occur most often in older adults include the following:
- Atrial fibrillation (atria beating 400–700 times per minute)
- Sick sinus syndrome (alternating episodes of bradycardia, NSR, tachycardia, and periods of long sinus pause)
- Heart block (delayed or blocked impulses to the atria or ventricles)

Age-related effects of dysrhythmias include the following:
- Weakness
- Fatigue
- Forgetfulness
- Palpitations
- Dizziness
- Hypotension
- Bradycardia
- Syncope

THERAPEUTIC MEASURES
If stable, obtain an ECG and treat the cause. Medications such as adenosine, calcium channel blockers, or beta blockers can be used to slow the heart rate (when ≥150 bpm; see Table 25.2). The treatment goal is to decrease the heart’s workload and resolve the cause, which then usually corrects the tachycardia. For example, if the patient is hemorrhaging, immediate intervention is needed to stop the bleeding and restore normal blood volume. Once normal blood volume is restored, the heart rate should return to normal.

LEARNING TIP
Tachycardia is often the first sign of hemorrhage. It is a compensatory mechanism to maintain cardiac output. If a patient develops sudden tachycardia, consider whether hemorrhage could be the cause, such as in postoperative patients, patients with gastrointestinal bleeding or cancer, or trauma patients. The bleeding may be external, or it may be internal and therefore not visible. Apply pressure to the site if the bleeding is obvious. Monitor the patient and report the tachycardia and any obvious bleeding promptly.

Dysrhythmias Originating in the Atria
As previously discussed, all areas of the heart can initiate an impulse. The SA node is the primary pacemaker, but if the atria initiate impulses faster than the SA node, they become the primary pacemaker. Atrial rhythms are usually faster than 100 bpm and can exceed 200 bpm. When an impulse originates outside the SA node, the P waves produced look different (flatter, notched, or peaked) from the rounded P waves from the SA node. This indicates that the SA node is not controlling the heart rate. These atrial impulses travel to the ventricles to initiate a normal QRS complex after each P wave.
Premature Atrial Contractions

The term premature refers to an “early” beat. When the atria fire an impulse before the SA node fires, a premature beat results. If the underlying rhythm is NSR, the distance between R waves is the same except where the early beat occurs. When looking at the ECG strip, a shortened R-to-R interval is seen where the premature beat occurs. The R wave preceding the premature atrial contraction (PAC) and the PAC’s R wave are close together, followed by a pause, with the next beat being regular (Fig. 25.16).

Etiology. Causes of PACs include hypoxia, cigarette smoking, stress, myocardial ischemia, enlarged atria in valvular disorders, medications (such as digoxin), electrolyte imbalances, atrial fibrillation onset, and heart failure.

Premature Atrial Contractions Rules.

1. Rhythm: premature beat interrupts underlying rhythm where it occurs
2. Heart rate: depends on the underlying rhythm; if NSR, 60 to 100 bpm
3. P waves: early beat is abnormally shaped
4. PR interval: usually appears normal, but premature beat could have shortened or prolonged PR interval
5. QRS interval: less than or equal to 0.10 seconds (indicates normal conduction to ventricles).

Atrial Flutter

In atrial flutter, the atria contract, or flutter, at a rate of 250 to 350 bpm. The very rapid P waves appear as flutter, or F waves, on ECG and appear in a sawtoothed pattern. Some of the impulses get through the AV node and reach the ventricles, resulting in normal QRS complexes. There can be from two to four F waves between QRS complexes. If impulses pass through the AV node at a consistent rate, the rhythm is regular (Fig. 25.17). The classic characteristics of atrial flutter are more than one P wave before a QRS complex, a sawtoothed pattern of P waves, and an atrial rate of 250 to 350 bpm.

Etiology. Causes of atrial flutter include rheumatic or ischemic heart diseases, congestive heart failure (CHF), hypertension, pericarditis, pulmonary embolism, and postoperative coronary artery bypass surgery. Many medications can also cause this dysrhythmia.

Atrial Flutter Rules.

1. Rhythm: atrial rhythm regular; ventricular rhythm regular or irregular depending on consistency of AV conduction of impulses
2. Heart rate: ventricular rate varies
3. P waves: flutter or F waves with sawtoothed pattern
4. PR interval: none measurable
5. QRS interval: less than or equal to 0.10 seconds.
SIGNS AND SYMPTOMS. The presence of symptoms in atrial flutter depends on the ventricular rate. If the ventricular rate is normal, usually no symptoms are present. If the rate is rapid, the patient may experience palpitations, angina, or dyspnea.

THERAPEUTIC MEASURES. The ventricular rate and cardiac output guide treatment. The goal is to control the ventricular rate with conversion to NSR. For an unstable patient with a rapid ventricular rate, synchronized cardioversion (electrical shock) is used. Rapid atrial pacing may also stop the atrial flutter. Medications are used to control the ventricular rate such as calcium channel blockers (see Table 25.2). Antiarrhythmic medications are used to control atrial flutter. To terminate the atrial flutter in symptomatic patients, a radiofrequency catheter ablation (usually in the right atrium) may be done.

Atrial Fibrillation

In atrial fibrillation (AF), the atrial rate is extremely rapid and chaotic. An atrial rate of 350 to 600 bpm can occur. However, the AV node blocks most of the impulses, so the ventricular rate is much lower than the atrial rate. There are no definable P waves because the atria are fibrillating, or quivering, rather than beating effectively. No P waves can be seen or measured. A wavy pattern is produced on the ECG. Because the atrial rate is so irregular and only a few of the atrial impulses are allowed to pass through the AV node, the R waves are irregular. The ventricular rate varies from normal to rapid.

AF can be self-limiting, persistent, or permanent, which doubles the risk of death. Stroke risk is increased due to thrombus formation in the atria from blood stasis caused by poor emptying of blood from the quivering atria (Fig. 25.18).

ETIOLOGY. Causes of AF include aging (increases after age 60 and is the most common sustained dysrhythmia), history of cigarette smoking, rheumatic or ischemic heart diseases, heart failure, hypertension, pericarditis, pulmonary embolism, and postoperative coronary artery bypass surgery and some medications.

ATRIAL FIBRILLATION RULES.
1. Rhythm: irregularly irregular
2. Heart rate: atrial rate not measurable; ventricular rate under 100 is controlled response; greater than 100 is rapid ventricular response
3. P waves: no identifiable P waves
4. PR interval: none can be measured because no P waves are seen
5. QRS interval: less than or equal to 0.10 seconds.

SIGNS AND SYMPTOMS. With AF, most patients feel the irregular rhythm. Many describe it as palpitations or a skipping heartbeat. A patient’s radial pulse may be faint because of a decreased stroke volume (volume of blood ejected with each contraction). If the ventricular rhythm is rapid and sustained, the patient can go into left-sided heart failure.

THERAPEUTIC MEASURES. The focus of AF treatment is to control rate, prevent thromboembolism, and restore normal rhythm. If the patient is unstable, synchronized cardioversion is done immediately to try to return the heart to NSR. For the patient who is stable, medications to control the ventricular rate such as beta blockers, calcium channel blockers, or digoxin are used (see Table 25.2). Anticoagulant therapy is given to reduce thrombi, which can cause a stroke. Pharmacological or electrical cardioversion may be performed to convert the rhythm after sufficient anticoagulation (about 3 weeks). Rhythm control medications such as sodium or potassium channel blockers are used to restore and maintain NSR. If known, the underlying cause of AF is treated.

For patients with AF who do not respond to medications or electrical cardioversion other therapies can be used.

Catheter Ablation. To isolate impulses coming from the pulmonary veins (most AF impulses arise from pulmonary veins) or AV node, catheter ablation may be used to cure AF. Intracardiac echocardiography maps the area of the heart requiring treatment. Then released energy such as radiofrequency waves create lesions either on all four pulmonary veins or near the AV node that heal and scar to block pathways for future impulses. Postprocedural care is similar to postangioplasty or postcardiac catheterization care (see Chapter 21).

Surgery. The MAZE procedure is often done as minimally invasive robotic-guided surgery. Incisions are made in the
atria that create a “maze,” or route, for electrical impulses to travel to the AV node. These impulses cannot go off course because scar tissue surrounds the incision sites.

**Ventricular Dysrhythmias**

Premature ventricular contractions (PVCs) originate in the ventricles from an ectopic focus (a site other than the SA node). The ventricles are irritable and fire prematurely, before the SA node does. When the ventricles fire first, the impulses are not conducted normally through the electrical pathway. This results in a wide (>0.10 seconds), bizarre QRS complex on an ECG (Fig. 25.19).

PVCs can occur in different shapes. The shape of the PVC is referred to as **unifocal** (one focus) if all the PVCs look the same because they come from the same irritable ventricular area. **Multifocal** PVCs do not all look the same because they are originating from several irritable areas in the ventricle. There can be several repetitive cycles or patterns of PVCs:

- **Bigeminy** is a PVC that occurs every other beat (a normal beat and then a PVC; Fig. 25.20).
- **Trigeminy** is a PVC that occurs every third beat (two normal beats and then a PVC).
- **Quadrigeminy** is a PVC that occurs every fourth beat (three normal beats and then a PVC).
- When two PVCs occur together, they are referred to as a couplet (pair).

- If three or more PVCs occur in a row, it is referred to as a run of PVCs or ventricular tachycardia.

**ETIOLOGY.** Use of caffeine or alcohol, anxiety, hypokalemia, cardiomyopathy, ischemia, and MI are common causes of PVCs.

**PREMATURE VENTRICULAR CONTRACTION RULES.**

1. **Rhythm:** depends on the underlying rhythm; PVC usually interrupts rhythm
2. **Heart rate:** depends on underlying rhythm
3. **P waves:** absent before PVC QRS complex
4. **PR interval:** none for PVC
5. **QRS interval:** if PVC, is greater than 0.10 seconds; T wave is in the opposite direction of QRS complex (i.e., QRS upright, T downward; or QRS downward, T upright).

**SIGNS AND SYMPTOMS.** PVCs may be felt by the patient and are described as a skipped beat or palpitations. With frequent PVCs, cardiac output can be decreased, leading to fatigue, dizziness, or more severe dysrhythmias.

**THERAPEUTIC MEASURES.** Treatment depends on the type and number of PVCs and whether symptoms are produced. Occasional PVCs do not usually require treatment. However, if the PVCs are more than six per minute, regularly occurring, multifocal, falling on the T wave (known as “R-on-T phenomenon,” which can trigger life-threatening dysrhythmias), or caused by an acute MI, they can be dangerous. Antidysrhythmic
drugs that depress myocardial activity are used to treat PVCs such as amiodarone and beta blockers (see Table 25.2).

**Ventricular Tachycardia**

The occurrence of three or more PVCs in a row is referred to as **ventricular tachycardia** (VT) (Fig. 25.21). VT results from the continuous firing of an ectopic ventricular focus. During VT, the ventricles rather than the SA node become the pacemaker of the heart. The pathway of the ventricular impulses is different from normal conduction, producing a wide (>0.10 seconds), bizarre QRS complex.

**ETIOLOGY.** Myocardial irritability, MI, and cardiomyopathy are common causes of VT. Respiratory acidosis, hypokalemia, digoxin toxicity, cardiac catheters, and pacing wires can also produce VT.

**VENTRICULAR TACHYCARDIA RULES.**
1. Rhythm: usually regular, may have some irregularity
2. Heart rate: 150 to 250 ventricular bpm; slow VT is below 150 bpm
3. P waves: absent
4. PR interval: none
5. QRS interval: greater than 0.10 seconds.

**SIGNS AND SYMPTOMS.** The seriousness of VT is determined by the duration of the dysrhythmia. Sustained VT compromises cardiac output. Patients are aware of a sudden onset of rapid heart rate and can experience dyspnea, palpitations, and lightheadedness. Angina commonly occurs. The severity of symptoms can increase rapidly if the left ventricle fails and complete cardiac arrest results.

**THERAPEUTIC MEASURES.** If the patient is pulseless or not breathing, cardiopulmonary resuscitation (CPR) and immediate defibrillation are required. Advanced cardiac life support (ACLS) protocols for pulseless VT treatment should be followed. Medications may include epinephrine, vasopressin, and amiodarone (see Table 25.2).

If the patient is stable, medications are tried first, such as amiodarone. Magnesium can be used to help stabilize ventricular muscle excitability if the patient’s magnesium level is low.

**Ventricular Fibrillation**

Ventricular fibrillation (VF) occurs when many ectopic ventricular foci fire at the same time. Ventricular activity is chaotic with no discernible waves (Fig. 25.22). The ventricle quivers and is unable to initiate a contraction. There is a complete loss of cardiac output. If this rhythm is not terminated immediately, death ensues.

**ETIOLOGY.** **Hyperkalemia** (elevated serum potassium), **hypomagnesemia** (low serum magnesium), electrocution, coronary

---

**CRITICAL THINKING**

**Mrs. Mae**

- Mrs. Mae, age 70, is 5 days post-MI without complications. You assist her back to bed at 1400 hours after she ambulates. Her oxygen is on at 2 L/min via nasal cannula. Her vital signs are BP 126/78 mm Hg, apical pulse 82 bpm, R 18 per minute. She has no pain and says she feels good after walking. The cardiac monitor shows normal sinus rhythm. Five minutes later, you see that the monitor shows sinus rhythm with PVCs of less than six per minute. Her vital signs are now BP 132/84 mm Hg, apical pulse 92 bpm, irregular, and R 22 per minute. She reports no pain but says, “I can feel my heart skipping. It takes my breath away.” You call the registered nurse (RN) while staying with the patient to provide reassurance.

1. What should you do first?
2. What should you do regarding the dysrhythmia?
3. What might be some of the causes for this dysrhythmia?
4. What symptoms, if any, would you expect to be present?
5. What would you do if symptoms were present?
6. With which health care team members might you collaborate?
7. What type of orders would you anticipate from the HCP?
8. How would you document your findings?

**Suggested answers are at the end of the chapter.**
artery disease, and MI are all possible causes of VF. Placement of intracardiac catheters and cardiac pacing wires can also lead to ventricular irritability and then VF.

**VENTRICULAR FIBRILLATION RULES.**
1. Rhythm: chaotic and extremely irregular
2. Heart rate: not measurable
3. P waves: none
4. PR interval: none
5. QRS complex: none.

**SIGNS AND SYMPTOMS.** Patients experiencing VF lose consciousness immediately. There are no heart sounds, peripheral pulses, or blood pressure readings. These are all indicative of circulatory collapse. Additionally, respiratory arrest, cyanosis, and pupil dilation occur.

**THERAPEUTIC MEASURES.** Immediate defibrillation is the best treatment for terminating VF. Each minute that passes without defibrillation reduces survival. CPR is started until the defibrillator is available. Automatic external defibrillators (AEDs) provide quick access to easily used technology for defibrillation (see the later “Defibrillation” section). Endotracheal intubation and ventilation support respiratory function. Medications are given according to ACLS protocols and may include epinephrine, vasopressin, amiodarone, and magnesium (see Table 25.2).

**Asystole**

Asystole (the silent heart) is the absence of electrical activity in the cardiac muscle. It is referred to as cardiac arrest. A straight line appears on an ECG strip (Fig. 25.23).

**ETIOLOGY.** VF and a loss of a majority of functional cardiac muscle due to an MI are common causes of asystole. VF usually precedes this rhythm and must be reversed immediately to help prevent asystole. Hyperkalemia is another cause of asystole.

**ASYSTOLE RULES.**
1. Rhythm: none
2. Heart rate: none
3. P waves: none
4. PR interval: none
5. QRS complex: none.

**SIGNS AND SYMPTOMS.** Patients in asystole are unconscious and unresponsive. There are no heart sounds, peripheral pulses, blood pressure readings, or respirations.

**THERAPEUTIC MEASURES.** CPR is started immediately. Endotracheal intubation to support respirations is performed. Epinephrine or vasopressin can be administered per ACLS protocols (see Table 25.2).
CARDIAC PACEMAKERS

Pacemakers can be temporary (epicardial, transcutaneous, transvenous) or permanent (Fig. 25.24). They are used to generate an electrical impulse when there is a problem with the heart’s conduction system.

Temporary pacemakers are used for bradycardia or tachycardia (overdrive pacing) that does not respond to medications or synchronized cardioversion. They may also be used after an MI to allow the heart time to heal when the diseased myocardium is unable to respond to or is not receiving electrical impulses because of damage within the conduction system. The temporary pacemaker becomes the electrical conduction system and stimulates the atria and ventricles to contract to maintain cardiac output. Temporary pacemakers can be inserted during valve or open heart surgery (epicardial), or in the cardiac catheterization lab or critical care unit (transvenous) as emergency treatment until surgery can be scheduled to implant a permanent pacemaker. Transcutaneous pacemakers are used in emergency situations because they are quick and easy to apply. Impulses are delivered to the heart through the skin from the external generator via electrodes that are attached to the chest and back.

CRITICAL THINKING

Mr. Peet

- You are making rounds. When you enter Mr. Peet’s room, you note that he is having difficulty breathing and is unresponsive.

1. What are your initial actions?
2. What should you do after assessing and finding no pulse or respirations?
3. What is your responsibility during a cardiac/respiratory arrest code?

Suggested answers are at the end of the chapter.

Permanent Pacemaker Implantation

Permanent pacemaker implantation is a procedure in which fluoroscopy, a screen that shows an image similar to a radiograph, is used. The pacemaker generator is implanted subcutaneously and attached to leads (insulated conducting wires) that are inserted via a vein into the heart. The lead then delivers the impulse directly to the heart wall. A single-lead pacemaker paces either the right atrium or right ventricle depending on its chamber placement. Dual-chamber pacemakers have two leads, with one in the right atrium and the other in the right ventricle. This allows pacing of both chambers. Activity-responsive pacemakers provide a rate range (e.g., 60–115 bpm) in response to a person’s activity level. This provides the patient with greater flexibility for increasing cardiac output when needed, such as during exercise.

When a patient is in a paced rhythm, a small spike (vertical line) is seen on the ECG at the start of the paced beat. This spike is the electrical stimulus. It can precede the P wave, QRS complex, or both depending on what is being paced (Fig. 25.25). Patients may have 100% paced beats, a mixture of their own beats and paced beats, or all of their own beats. Pacemakers should not fire on patients’ own beats.

Problems that can occur with pacemakers include the following:

- Failure to sense a patient’s own beat
- Failure to pace because of a malfunction of the pulse generator
- Failure to capture, which is the heart’s lack of depolarization

Nursing Care for Patients With Pacemakers

Patients’ heart rhythm, apical pulse, and incision are monitored after implantation of a pacemaker. Irregular heart rhythms or a rate slower than the pacemaker’s set rate can indicate pacemaker malfunction. Any change in heart rhythm, reports of chest pain, or changes in vital signs are reported immediately. The patient may remain in the hospital overnight.

Pacemaker care teaching before discharge includes the following:

- Report signs of incision infection (redness, swelling, warmth, pain, fever, or discharge) to the HCP.
- Care for incision as instructed (dressing removal, keep clean and dry, resuming showers).
- Report chest pain, dizziness, fainting, irregular heartbeats, palpitations, muscle twitching, or hiccups.
- Maintain ordered activity restrictions (limiting raising arm on pacemaker side, driving, return to work).
- Carry your pacemaker ID card to show to HCPs, airport security, or other security staff. Pacemaker metal may set off alarms but is not harmed if one walks normally through the security device. Avoid having a hand wand passed over the pacemaker.
- Understand electromagnetic restrictions to follow. Information is available on pacemaker manufacturer websites regarding various devices. Avoid strong electromagnetic fields (such as magnetic resonance imaging [MRI] unless it is the complete Revo MRI SureScan pacing system designed for use with MRI, welders above 130 amps, radio towers, or touching running car engines).
- Microwaves and most common household devices may be used.
- Keep cell phone of 3 watts or less 6 inches from your generator and on opposite side.
- If become lightheaded or dizzy near an electromagnetic device, move away from it.
- Keep scheduled appointments with the HCP. Periodic pacemaker checks will be done either by the HCP or remotely from home. The HCP can reprogram the pacemaker if needed.

**CRITICAL THINKING**

**Mr. Treacher**

Mr. Treacher, age 58, underwent pacemaker placement 6 days ago and is being transferred to the medical floor. After transfer, his vital signs are BP 138/72 mm Hg, apical pulse 72 bpm, and 100% paced rhythm.

Thirty minutes later, he says that he feels weak and tired. His vital signs are now BP 100/60 mm Hg, apical pulse 60 bpm, and irregular.

1. What is your first action?
2. What actions should be taken next?
3. What might be happening to Mr. Treacher?
4. What interventions should you anticipate next?

Suggested answers are at the end of the chapter.

**DEFIBRILLATION**

**Defibrillation** is a lifesaving procedure used for pulseless VT or VF. It delivers an electrical shock to reset the heart’s rhythm. Self-adhesive pads, conductive jelly, or saline pads are placed on the patient’s chest to prevent electrical burns and promote conduction of the electrical charge. After the defibrillator is charged, the paddles are pressed firmly and evenly against the chest wall to prevent burns or electrical arcing (Fig. 25.26).

For safety, the person who is defibrillating must announce “Clear.” The phrase “One. I’m clear. Two. You’re clear. Three. All clear” is suggested. No one, including the person defibrillating, should touch the bed or patient during this time to avoid also being shocked. ACLS protocols specify the guidelines for resuscitation.
After the procedure, the patient is monitored for skin burns, rhythm disturbances, vital sign changes, respiratory problems, hypotension, and changes in the ST segment.

**OTHER METHODS TO CORRECT DYSRHYTHMIAS**

**Automatic External Defibrillators**

An AED is an external device that automatically analyzes rhythms and either automatically delivers or prompts operators to deliver an electrical shock if a shockable rhythm (VF or VT) is detected (Fig. 25.27). Minimally trained laypersons or hospital and rescue personnel can use these devices with little risk of injury to the patient because the AED analyzes the rhythm rather than the operator. The patient is connected to the AED with adhesive sternal-apex pads attached to cables coming from the device. This connection allows hands-free defibrillation.

AEDs are found in public places such as shopping malls, airports, stadiums, casinos, golf courses, and airplanes for immediate access because defibrillation attempts must occur within minutes of cardiac arrest to increase chance of survival. AEDs are available for home use. They are recommended for people at high risk of sudden cardiac arrest and for those at risk with rescue access that will take longer than 4 minutes, such as people living in rural areas, gated communities, or secured-access buildings.

**Implantable Cardioverter Defibrillator**

An implantable cardioverter defibrillator (ICD) or a combination pacemaker/ICD is placed into the chest of a patient who experiences life-threatening dysrhythmias or is at risk for sudden cardiac death (Fig. 25.28). ICDs have decreased the number of deaths from these dysrhythmias by analyzing and treating these heart rhythms. When an abnormal rhythm is detected that could cause death (VF), it automatically delivers an electrical shock. If the dysrhythmia does not convert on the initial shock, more shocks are delivered sequentially.

Cardioversion is performed with a defibrillator set in the synchronized mode. When the defibrillator is in the synchronized mode, it marks a highlighted area on the patient’s R waves, which must be recognized to deliver a shock. When the discharge trigger is pressed, the shock is released when the machine senses it is safe to do so. The number of joules delivered with each shock usually ranges from 25 to 50. The procedure for delivering the shock is the same as for defibrillation.

Synchronized cardioversion is used for ventricular tachycardia with a pulse. Elective synchronized cardioversion is used for dysrhythmias such as AF, atrial flutter, and supraventricular tachycardia that are not responsive to drug therapy. The patient is given a sedative and monitored by anesthesia personnel during the procedure.

If cardioversion is successful, there should be a return to NSR. If the rhythm does not immediately convert, more cardioversion attempts can be made as determined by the HCP.

After successful defibrillation, the patient is assessed for a pulse and adequate tissue perfusion. The patient is treated in the critical care unit (CCU) after successful resuscitation.

Emotional support for an alert patient having experienced cardiac arrest and defibrillation is an important aspect of nursing care. This can be an extremely frightening event for the patient. It is important to explain to the patient what happened and to listen and allow him or her to express concerns. The patient is reassured that continuous cardiac monitoring is done in the CCU. Families also require emotional support during resuscitation of a loved one and might be present during it per agency policy.

After the procedure, the patient is monitored for skin burns, rhythm disturbances, vital sign changes, respiratory problems, hypotension, and changes in the ST segment.
If the device detects VT, it cardioverts the rhythm using lower energy. ICDs also have antitachycardia pacing ability if a tachycardic rhythm is detected. Battery life depends on usage. When the battery is getting low, the entire unit needs to be changed within a few months.

Patients with ICDs can be extremely anxious about receiving shocks from the ICD. Defibrillator or cardioversion shocks may feel like a kick in the chest. Reinforcement of patient and family education is important. To prevent problems, those with ICDs should take the same precautions as discussed earlier with pacemakers. Provide emotional support, answer questions, and ensure that any misunderstood information is corrected before discharge.

**Home Health Hints**
- A cell phone affords a home health nurse safety, convenience, and efficiency, especially if emergency help is needed, because some patients do not have phones.
- The nurse should have a pocket mask for CPR available at all times.
- Patients prone to dysrhythmias should avoid straining with bowel movements. If the patient reports straining, request a laxative or stool softener order from the HCP.
- Patients on beta blockers and inotropic agents (digoxin) need to know how to take their radial pulse, because bradycardia is a major side effect. For a pulse below 50 bpm, call the HCP.
- Visual disturbances can occur from digitalis toxicity. If the patient sees halos around lights or red-green tinting on everything, report this to the HCP.
- Blood drawn for digoxin (Lanoxin) levels, frequently prescribed for dysrhythmia, should be taken to the lab within 2 to 3 hours.
- Advise patients who are leaving home for the weekend or holidays to refill medicines ahead of time. Also, the HCP may write a prescription for patients to keep in their wallet for emergencies.
- Patients who come home with a pacemaker should be instructed to wear loose tops. Women should not wear tight bras.
- Follow patient teaching guidelines discussed earlier in the chapter.
- If the patient is discharged with a prescription for an anticoagulant, educate the patient and family regarding follow-up appointments, dietary needs, complication (signs and symptoms of active bleeding: hematuria, bleeding gums, frequent bruising, or dark stools).
### NURSING CARE PLAN for the Patient With Dysrhythmias

**Nursing Diagnosis:** Decreased Cardiac Output related to dysrhythmias  

**Expected Outcomes:** The patient’s cardiac status will be stabilized. Patient will be able to tolerate activities of daily living (ADLs).

**Evaluation of Outcomes:** There is an absence of dysrhythmias. Patient is able to perform ADLs without tachycardia, chest pain, or weakness.

**Intervention**  
- Take apical and radial pulses every 2 to 4 hours. Monitor blood pressure and urinary output.  
**Rationale** Monitors for dysrhythmias, impending cardiac arrest, or shock. Blood pressure, pulse, and urinary output are indicators of cardiac output. **Evaluation** Is the patient free of dysrhythmias with vital signs within normal limits?  
- Monitor mental status every 2 to 4 hours. **Rationale** Dizziness, confusion, and restlessness may indicate decreased cerebral blood flow. **Evaluation** Does patient show signs of decreased cerebral perfusion, such as confusion?  
- Listen to lung sounds every 2 to 4 hours. **Rationale** Dysrhythmias can cause heart failure. **Evaluation** Are lungs clear with no report of dyspnea?  
- Administer O₂ as ordered. **Rationale** Increases oxygenation to the heart and brain. **Evaluation** Is patient free of chest pain, confusion, and light-headedness?  
- Ensure that patient gets adequate rest and does not exceed activity tolerance. **Rationale** Reduces dyspnea and decreases O₂ demand on the myocardium. **Evaluation** Does patient rest and tolerate activity without dyspnea or chest pain?  

**Geriatric**  
- Administer medications as ordered and observe for adverse reactions. **Rationale** Older patients may have decreased renal and liver function that may lead to rapid development of toxicity. **Evaluation** Does patient have signs of toxicity?

**Nursing Diagnosis:** Anxiety related to situational crisis  

**Expected Outcomes:** The patient will be able to effectively manage anxiety. Patient will report decreased anxiety.  

**Evaluation of Outcomes:** Patient uses effective coping mechanisms to manage anxiety. Patient expresses decreased anxiety.

**Intervention**  
- Ask about level of anxiety. **Rationale** Establishes a baseline. **Evaluation** What is patient’s level of anxiety?  
- Encourage patient and family to verbalize fears. **Rationale** Helps correct and clarify their concerns. **Evaluation** What are patient’s feelings or fears?  
- Explain procedures to patient and family. **Rationale** Lack of knowledge increases anxiety. This knowledge will help with compliance of therapy. **Evaluation** Does patient express understanding of therapy with decreased anxiety?  
- Identify and reduce as many environmental stressors as possible. **Rationale** Anxiety often results from lack of trust in the environment. **Evaluation** Can patient describe two situations that increase tension?  
- Teach patient relaxation techniques to be performed every 4 to 6 hours, such as guided imagery, muscle relaxation, and meditation. **Rationale** These measures can restore psychological and physical equilibrium and help decrease anxiety. **Evaluation** Is patient successful in demonstrating relaxation methods?  
- Medicate with antianxiety agents as ordered. **Rationale** Aids the patient in decreasing anxiety. **Evaluation** Does patient show decreased anxiety?
## SUGGESTED ANSWERS TO CRITICAL THINKING

### Mrs. Mae
1. Assess the patient’s vital signs and heart sounds, note symptoms, obtain an ECG per agency protocol.
2. Report the patient findings to the RN or HCP.
3. Possible causes include hypokalemia or ischemia leading to irritability of the heart.
4. Symptoms might include lightheadedness, feeling of heart skipping, chest pain, or fatigue.
5. To alleviate symptoms, elevate head of bed to comfort, monitor vital signs, and maintain oxygen at 2 L/min via nasal cannula per agency protocol. Remain with the patient to help alleviate anxiety. Notify the RN.
6. RN, respiratory therapist, HCP
7. Orders might include ECG, oxygen, potassium, or electrolytes.
8. Documentation should include the following:
   - Tolerated well. Assisted to bed. Oxygen at 2 L/min via nasal cannula.
   - 1405: see ECG strip with intermittent PVCs. Vital signs: BP 132/84 mm Hg; apical 92 bpm, irregular; R 22 per minute.
   - “Pain zero. I can feel my heart skipping, it takes my breath away.” RN notified.

### Mr. Peet
1. Initially you should assess responsiveness and the presence of a carotid pulse. Check for breathing.
2. Open the airway. Call for assistance or use the patient’s phone to report a cardiac arrest. Initiate CPR until help arrives.
3. Once help or the code team arrives, the licensed practical nurse/licensed vocational nurse (LPN/LVN) reports the patient’s status. The code team leader delegates responsibilities. Many facilities have protocols for each team member in a code. The LPN/LVN assists in the code as delegated by the RN in charge.

### Mrs. Parker
1. A heart in VT has an ectopic focus that is initiating impulses. The heart is unable to maintain adequate cardiac output with such a rapid heart rate. The rapid and irregular heart rhythm does not allow the heart chambers time to adequately fill and empty, thereby reducing the blood volume with each beat. This in turn affects the peripheral circulation, causing the absence of palpable pulses.
2. In VT, one or more sites in the ventricle may be initiating impulses. The rapid rate of VT overrides the normal pacemaker of the heart. The rhythm can be regular or irregular. The inability of the heart to conduct impulses along normal pathways prevents the chambers from emptying and filling properly. This leads to a decreased cardiac output and can lead to cardiac arrest if the rhythm is not converted.
3. Call a code and begin CPR. Report findings to code team upon their arrival.
4. Documentation should include the following: 1600: Patient found in bed unresponsive to verbal and tactile stimuli. Respirations shallow. No palpable pulses. BP 80/40 mm Hg, P 150 bpm, R 6 per minute. Monitor shows VT (see strip). Code called from room. CPR started. Code team arrived at 1602. Report given to code team leader.

### Mr. Treacher
1. Your first actions should be to obtain an ECG per agency protocol and to notify the RN or HCP.
2. You should keep the head of the bed elevated and administer oxygen at 2 L/min via nasal cannula per protocol. Turn the patient onto his side because this may help float the pacemaker wire to the chamber wall for better contact. Monitor the patient’s ECG, vital signs, and symptoms, and remain with patient to provide emotional support.
3. Mr. Treacher could be experiencing pacemaker malfunction.
4. Interventions could include transfer to a step-down unit or CCU for reprogramming of the pacemaker, or a return to surgery for manipulation or replacement of the pacemaker wires.
1. Place the following in the correct sequence for normal electrical impulse movement through the cardiac conduction system.
   1. AV node
   2. SA node
   3. bundle of His
   4. Purkinje fibers
   5. Internodal tracts
   Sequence: ______________

2. The nurse prepares to document an ECG rhythm. The nurse uses a systematic method for analyzing the ECG tracing for which of the following reasons?
   1. So abnormalities are not missed.
   2. To save time.
   3. To develop a routine for examining tracings.
   4. To increase memory of the analysis steps.

3. The nurse responds to a call for assistance for a patient in pulseless ventricular tachycardia. The nurse should prepare for which of the following as the first choice of treatment for this rhythm?
   1. Synchronized cardioversion
   2. Pacemaker
   3. Defibrillation
   4. Antiarrhythmic medication

4. The nurse is to provide teaching to a patient after insertion of a pacemaker. Which of the following instructions should the nurse give the patient regarding pacemaker care?
   1. “Avoid microwaves.”
   2. “All pacemaker types are compatible with MRI.”
   3. “Avoid strong electromagnetic devices.”
   4. “You will need to be on bedrest for 48 hours.”

5. The nurse is ambulating a patient who is recovering from an MI when the patient develops chest pain with an irregular pulse. Which of these is safest way for the nurse to return the patient to bed?
   1. Ambulation to room with one assistant.
   2. With assistance by gurney.
   3. With assistance by a wheelchair.
   4. After completion of ambulation.

6. A patient has a radial pulse of 58 bpm. Which of the following should the nurse use to document this finding?
   1. Normal
   2. Asystole
   3. Tachycardia
   4. Bradycardia

7. The nurse is to give a patient amiodarone 800 mg/day PO in two divided doses. The nurse has available 200-mg tablets. How many tablets should the nurse give for each dose? Fill in the blank.
   Answer: ______________ tablets

Answers can be found in Appendix C.
Nursing Care of Patients With Heart Failure

KATHY BERCHEM

LEARNING OUTCOMES

1. Describe the pathophysiology of left- and right-sided heart failure.
2. Define acute heart failure.
3. List causes of acute and chronic heart failure.
4. Identify signs and symptoms of acute and chronic heart failure.
5. Plan nursing care for patients undergoing diagnostic tests for heart failure.
6. Explain medical treatments used for acute and chronic heart failure.
7. Plan nursing care for acute and chronic heart failure.

KEY TERMS

afterload (AFF-ter-lohd)
cor pulmonale (KOR PUL-mah-NAH-lee)

pulmonary edema (PULL-muh-NARE-ee eh-DEE-muh)
splenomegaly (SPLEE-noh-MEG-ah-lee)
OVERVIEW OF HEART FAILURE

Heart failure (HF) is a clinical syndrome that occurs as a result of the inability of the ventricle(s) to fill or pump enough blood to meet the body’s oxygen and nutrient needs. It may cause dyspnea, fatigue, and fluid volume overload in the intravascular and interstitial spaces, resulting in reduced quality and length of life. Causes of HF are varied and may include coronary artery disease (most often), myocardial infarction (MI), cardiomyopathy, heart valve problems, and hypertension. Any heart problem can potentially lead to HF. In the older adult, the most common cause of HF is cardiac ischemia. It may develop rapidly (acute), as with cardiogenic shock and pulmonary edema, or over time (chronic) as a result of another disorder, such as hypertension or pulmonary disease.

The incidence of HF is growing as the older adult population and patient survival rates increase. According to the American Heart Association (AHA; Go et al, 2014), 5.1 million people have HF with more than 670,000 new cases each year. HF is the most common reason for hospital admission in the older adult. The patient may experience many functional limitations and symptoms, and according to the Centers for Disease Control and Prevention (2013), the mortality rate is as high as 597,000 deaths per year. Quality of life is often impaired. Readmission rates to hospitals soon after discharge for HF treatment are high and pose a challenge for health care providers (HCPs). For more information, visit www.americanheart.org.

Congestive Heart Failure

Congestive HF is an older term for HF. It is still used interchangeably by some to indicate HF; the preferred term. This is because volume overload or “congestion” either in the lungs or periphery is not present in everyone with HF or at all times.

Pathophysiology

The heart is divided into two separate pumping systems, the right side of the heart and the left side of the heart. Proper cardiac functioning requires each ventricle to pump out equal amounts of blood over time. If the amount of blood returned to the heart becomes more than either ventricle can handle, the heart can no longer function effectively as a pump.

Left-Sided Heart Failure

The left ventricle must generate a certain amount of force during a contraction to eject blood into the aorta through the aortic valve. This force is referred to as afterload. The pressure within the aorta and arteries acts as resistance and influences the force required to open the aortic valve to pump blood into the aorta. This pressure is called peripheral vascular resistance (PVR). Hypertension is one of the major causes of left-sided HF because it increases the pressure within arteries. Increased pressure in the aorta makes the left ventricle work harder to pump blood into the aorta. Over time the strain caused by the increased workload causes the left ventricle to weaken and fail. Other conditions that can lead to left-sided HF are described in Table 26.1.
With left-sided HF, blood backs up from the left ventricle into the left atrium and then into the four pulmonary veins and lungs (Fig. 26.1). This increases pulmonary pressure, causing movement of fluid first into the interstitium and then into the alveoli. Alveolar edema is more serious because it reduces gas exchange across the alveolar capillary membrane. Shortness of breath and cyanosis may result from the decreased oxygenation of the blood leaving the lungs. If the fluid buildup is severe, acute pulmonary edema occurs, which requires immediate medical treatment.

### Right-Sided Heart Failure

Conditions causing right-sided HF increase the work of the right ventricle. They increase the amount of contractile force needed or require pumping of excess blood volume (preload). Causes of right-sided HF are described in Table 26.2. The major cause of right-sided HF is left-sided HF when the left side fails, fluid backs up into the lungs and pulmonary pressure is increased. The right ventricle must continually pump blood against this increased fluid and pressure in the pulmonary artery and lungs. Over time this additional strain eventually causes it to fail. When the right ventricle hypertrophies or fails because of increased pulmonary pressures, it is referred to as **cor pulmonale**.

When the right ventricle fails, it does not empty normally, and there is a backward buildup of blood in the systemic blood vessels. As the blood backs up from the right ventricle, right atrial and systemic venous blood volume increases. The jugular neck veins, which are not normally visible, become distended and can be seen when the person is in a 45-degree upright position. Edema may occur in the peripheral tissues, and the abdominal organs can become engorged (Fig. 26.2). Fluid congestion in the gastrointestinal (GI) tract causes anorexia, nausea, and abdominal pain. As the failure progresses, blood pools in the hepatic veins, and the liver becomes congested (hepatomegaly). This liver congestion also

causes pain in the right upper quadrant of the abdomen and impairs liver function. Systemic venous congestion also leads to engorgement of the spleen (splenomegaly).

PULMONARY EDEMA (ACUTE HEART FAILURE)

Pulmonary edema, also known as acute HF, is sudden severe fluid congestion in the alveoli of the lungs and is life threatening. Pulmonary edema occurs with an acute event such as a MI or when the heart is severely stressed, causing the left ventricle to fail. Complications of pulmonary edema include dysrhythmias and cardiac arrest.

Pathophysiology
First, pressure rises in the lung’s venous blood vessels as blood builds up. As pressures continue to rise, fluid moves into the interstitial spaces. Then, with continued pressure increases, fluid containing red blood cells (RBCs) leaks into the alveoli. Finally, the alveoli and airways become filled with fluid, reducing gas exchange and oxygen levels.

Signs and Symptoms
Signs and symptoms of pulmonary edema are listed in Table 26.3. Pink, frothy sputum is a classic symptom of pulmonary edema caused by the increased lung congestion and pressures that allow leaking of fluid and RBCs into the alveoli. Compensatory mechanisms increase the heart rate and blood pressure; however, as pulmonary edema worsens, the blood pressure may fall.

Diagnostic Tests
Diagnostic studies are listed in Table 26.3. The congestion in the pulmonary system can be seen on x-ray examination. Arterial blood gases (ABGs) show a decrease in PaO₂ that continues as the edema worsens and an increase in PaCO₂, causing respiratory acidosis. The pulmonary artery catheter shows elevated pulmonary pressures and a decreased cardiac output.

Therapeutic Measures
Immediate treatment is needed to prevent patients from drowning in their own secretions (see Table 26.3). The goal...
of therapy is to reduce the workload of the left ventricle in order to improve cardiac output and reduce the patient’s anxiety. Placing the patient in Fowler’s position allows the lungs to expand more easily. Ask the patient what position provides him or her the most comfort in breathing. Oxygen is given, usually by mask to provide higher amounts. In severe cases of pulmonary edema, endotracheal intubation and mechanical ventilation may be necessary.

Medications are given intravenously to reduce anxiety, relax airways, increase peripheral blood pooling to decrease preload, reduce fluid congestion, strengthen heart contractions, reduce arterial pressure (afterload) and sodium and water retention to relieve dyspnea.

**Nursing Care**

The patient is typically critically ill and in an intensive care unit (ICU). Psychosocial supportive care is important because the patient will be anxious if alert.

**CHRONIC HEART FAILURE**

**Signs and Symptoms**

Chronic HF is a progressive disorder. Signs and symptoms worsen over time (Table 26.4).

**Fatigue and Weakness**

Fatigue and weakness are the earliest symptoms of HF. They occur from the decreased amount of oxygen reaching the tissues. During the day, the fatigue worsens, especially with activity.

**Dyspnea**

Dyspnea is a common symptom of left-sided HF. It is a result of the pulmonary congestion that impairs gas exchange.

between the alveoli and capillaries. Dyspnea stimulates compensatory mechanisms that produce short, rapid respirations. Dyspnea is classified in several ways:

- **Exertional dyspnea** is shortness of breath that increases with activity.
- **Orthopnea** is dyspnea that increases when lying flat. In an upright position, gravity holds fluid in the lower extremities. In a supine position, gravitational forces are removed, allowing fluid to move from the legs to the heart, which overwhelms the already congested pulmonary system. When orthopnea is present, two or more pillows are often used for sleeping. Documentation should state the number of pillows used. For example, use of three pillows would be “three-pillow orthopnea.”

- **Paroxysmal nocturnal dyspnea** (PND) is sudden shortness of breath that occurs after lying flat for a time. PND results from excess fluid accumulation in the lungs. The sleeping person awakens with feelings of

---

**ORTHOPNEA**

*orth—straight + pnea—to breathe*
suffocation and anxiety. Relief is obtained by sitting upright for a short time, which reduces the amount of fluid returning to the heart.

Cough
A chronic, dry cough is common in HF. The coughing increases when lying down from increased irritation of the lung mucosa. This irritation is due to the increase in pulmonary congestion that occurs when gravity no longer keeps fluid in the legs and more fluid returns to the heart and lungs.

Crackles and Wheezes
Pulmonary congestion causes abnormal breath sounds such as crackles and wheezes. Crackles are produced from fluid buildup in the alveoli resulting from increased pressure in the pulmonary capillaries. Wheezes occur from bronchiolar constriction caused by the increased fluid.

Tachycardia
The sympathetic nervous system compensates for the decreased cardiac output in HF by releasing epinephrine and norepinephrine to increase the heart rate. Normally, this is helpful because the increased heart rate increases the amount of blood ejected by the heart to maintain an adequate cardiac output. However, whenever the heart works faster, the heart itself also requires more oxygen, which the failing heart finds difficult to supply.

Edema
Edema occurs in HF as a result of (1) systemic blood vessel congestion and (2) sympathetic compensatory mechanisms that cause the kidneys to activate the renin-angiotensin-aldosterone system, in which antidiuretic hormone is released from the pituitary gland, causing sodium and water to be retained. Systemic edema or pulmonary edema can occur in HF. The effect of backward buildup of pressure in the systemic blood vessels is seen with distention of the jugular veins, swelling of the legs and feet, sacral edema in the individual on bed rest, and increased fluid within the abdominal cavity and organs (ascites). An acute buildup of fluid in the lungs produces pulmonary edema.

Anemia
Many patients with HF are anemic due to hemodilution from fluid overload, and decreased angiotensin-converting enzyme (ACE) action. The reduced ACE action decreases erythropoietin release, resulting in decreased production of RBCs.

Nocturia
Nocturia is an increase in urine output at night during sleep. After lying down, fluid in the lower legs returns to the circulatory system. Renal blood flow and filtration are increased, resulting in greater urine production and the need to urinate frequently during the night. Nocturia may occur up to six times per night, contributing to the patient’s fatigue from lack of sleep.

Cyanosis
The skin, nail beds, or mucous membranes may appear blue, or cyanotic, from decreased oxygenation of the blood. Cyanosis is a late sign of HF. It is associated primarily with left-sided HF.

Altered Mental Status
Reduced cardiac output decreases the amount of oxygen delivered to the brain. As a result, restlessness, insomnia, confusion, decreased level of consciousness, and impaired memory may occur.
Malnutrition

Several factors contribute to malnutrition in the person with chronic HF. Altered mental status, dyspnea, and fatigue interfere with the ability to eat. Anorexia and GI upset occur from pressure exerted by excess fluid surrounding the GI structures (ascites). This pressure may also impair absorption of food.

Complications of Heart Failure

Complications of HF are listed in Table 26.4. The liver and spleen enlarge from the fluid congestion, which causes impaired function, cellular death, and scarring. The elevated pressures in the capillaries of the lung can cause a pleural effusion, which is a leakage of fluid from the capillaries of the lung into the pleural space. Thrombosis and emboli can occur as a result of poor emptying of the venules, which leads to stasis of blood. Aspirin or anticoagulants are often prescribed to prevent thrombus formation in patients with HF. Cardiogenic shock, often caused by an MI that damages the left ventricle, occurs when the left ventricle is unable to supply the tissues with enough oxygen and nutrients to meet their needs. Cardiogenic shock is a life-threatening condition that requires immediate treatment (see Chapter 9).

Diagnostic Tests

Diagnostic tests are done to identify the cause of HF and determine the degree of failure present (see Table 26.4):

- Serum laboratory tests can evaluate contributing factors for HF, such as elevated serum blood urea nitrogen (BUN) and serum creatinine from renal failure, elevated liver enzymes from liver damage, elevated ferritin with hemochromatosis (iron overload), and thyroid function tests.

- A serum B-type natriuretic peptide (BNP) or N-terminal proBNP (NT-proBNP) level may be obtained. Elevated levels indicate HF and severity; higher levels of this cardiac biomarker correlate with a worse prognosis. BNP is made by the heart to regulate blood volume to reduce cardiac workload. When the heart has to work harder over time, it releases more BNP.

- Elevated serum cystatin C (a protein produced by all nucleated cells) is a risk factor for HF.

- A chest x-ray examination shows the size, shape, and any enlargement of the heart as well as congestion in the pulmonary vessels.

- Cardiac dysrhythmias that precipitate and contribute to HF are diagnosed with an electrocardiogram (ECG; see Chapters 21 and 25).

- Echocardiography may measure ventricular size, wall thickness, motion, and ejection fraction and assess valvular function.

- Exercise stress testing and nuclear imaging studies show activity tolerance, which is usually limited in HF.

- Cardiac magnetic resonance imaging (MRI) shows both moving and still pictures of the heart and major blood vessels. Cardiac structure and function are analyzed to determine treatment for cardiac disease.

- Cardiac catheterization and angiography are used to detect underlying heart disease that may be the cause of HF.

- Sleep studies may be done because sleep apnea or breathing disorders can contribute to HF.

- Measurement of the pressure in the heart and lungs is done with hemodynamic monitoring to guide medical therapy.

Therapeutic Measures

The overall goal of medical treatment for chronic HF is to improve the heart’s pumping ability and decrease the heart’s oxygen demands. Treatment of HF focuses on (1) identifying and correcting the underlying cause, (2) increasing the strength of the heart’s contraction, (3) maintaining optimum water and sodium balance, and (4) decreasing the heart’s workload. HF management requires a team approach that may involve physicians, nurse practitioners, case managers,
nurses, dietitians, physical therapists, occupational therapists, pharmacists, social workers, and clergy. HF critical pathways (treatment guidelines) as well as HF clinics are used to ensure quality-based outcomes while reducing treatment costs.

The severity of HF determines the individualized therapy selected. Noninvasive approaches are usually tried first. If noninvasive treatment is not effective, invasive approaches may be used. Often, multiple therapies are used in combination for optimum patient outcomes.

**Oxygen Therapy**

One of the major problems caused by HF is a reduction in oxygen delivered to the tissues. The signs and symptoms of this are fatigue, dyspnea, altered mental status, and cyanosis. Oxygen therapy may assist in supplying the oxygen needs of the tissues. In mild HF, oxygen may be delivered via nasal cannula. For more severe cases, ABG values guide oxygen delivery, either via masks that provide high concentrations of oxygen or with mechanical ventilation.

**Activity**

Activity tolerance depends on the severity of HF signs and symptoms. Severe symptoms may require bed rest with restricted activity until treatment reduces the symptoms. For stable HF, a regular exercise program, such as one set up with referral to a cardiac rehabilitation program, has shown to improve cardiac function and reduce HF effects (see “Evidence-Based Practice”). Patients should be encouraged to stay as active as possible within the parameters of the collaborative plan set up with the health care team. An individualized walking program that increases activity over time is often prescribed. Patients are educated on how to exercise safely and how to identify symptoms they may have to prevent overexertion and worsening of symptoms.

---

**EVIDENCE-BASED PRACTICE**

**Clinical Question**

Do cardiovascular rehabilitation programs improve quality of life for HF patients?

**Evidence**

In a randomized controlled study of 123 medically stable HF patients over 10 years, exercise training demonstrated improved functional capacity and quality of life over patients who did not exercise regularly (Belardinelli, Georgiou, Cianci, & Purcaro, 2012). Cardiac rehabilitation has shown long-term benefits also in a randomized controlled trial (Porto et al, 2012). In the study, patients with chronic HF who participated in a supervised cardiac rehabilitation program, compared with nonparticipants, demonstrated improved cardiovascular fitness, functional capacity, quality of life, and an increase in survival along with a reduction in need for emergency treatment.

**Implications for Nursing Practice**

Cardiac rehabilitation programs for chronic HF patients have been shown to improve quality of life. Nurses should initiate referrals to cardiac rehabilitation programs and educate patients on their value toward overall cardiac health.

**REFERENCES**

---

**Sodium Restriction and Weight Control**

Dietary sodium is restricted to decrease fluid retention. Salt substitutes often use potassium in place of sodium, so the patient and HCP should discuss their use. A healthy weight range should be maintained, and a dietitian consult can include a plan for a low-sodium diet and weight reduction if needed.

---

**BE SAFE!**

In severe HF with abdominal discomfort present, malnutrition is a concern. The patient can be anorexic, but the weight gain that occurs with fluid retention can mask the weight loss occurring from the anorexia. Monitor food intake to ensure that weight gain from fluid retention does not allow malnutrition to go undetected.

---

**Drug Therapy**

There is no cure for HF. Medications, however, can improve symptoms and quality of life. The American College of Cardiology Foundation/American Heart Association (ACC/AHA) 2013 guidelines recommend medication classes with qualifiers for the following stages of HF development (Yancy et al, 2013):

- **Stage A** refers to people at high risk of HF.
- **Stage B** is those who have no HF symptoms but do have structural heart disease.
- **Stage C** applies to people with current or past symptoms of HF with structural heart disease. This includes most patients with HF.
- **Stage D** includes those with refractory HF, which requires extraordinary support or hospice care.
In general, drug categories begin with angiotensin-converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARBs) to control hypertension if present in Stage A, then add beta blockers (bisoprolol, carvedilol, metoprolol succinate SR) along with the ACE inhibitors or ARBs for Stage B, then diuretics for fluid retention, and consideration of aldosterone antagonists, nitrates, digitalis, and hydralazine (Apresoline) for Stage C (Table 26.5). Anticoagulants are also used on an individual risk basis.

**LEARNING TIP**
To help you identify ACE inhibitors, remember that their generic names end with -pril.

**ANGIOTENSIN-CONVERTING ENZYME INHIBITORS.** ACE inhibitors are considered the first-choice drug over angiotensin receptor blockers (ARBs). They are used for their vasodilation effect, which lowers blood pressure and reduces workload on the heart. They also offer additional benefit by preventing remodeling, which is an effect that leads to progressive cardiac deterioration.

**ANGIOTENSIN RECEPTOR BLOCKERS.** ARBs are an alternative to ACE inhibitors for inhibiting the renin-angiotensin-aldosterone system, thereby lowering blood pressure and workload on the heart. They should be used carefully if ACE inhibitors are also used because hypotension, hyperkalemia, and renal dysfunction risks increase.

**BETA-ADRENERGIC BLOCKERS.** Initially the sympathetic nervous system (SNS) acts to compensate for HF. Long-term

ACE = angiotensin-converting enzyme.

sympathetic effects, however, are not helpful in HF. Beta-blockers block the adverse effects of the SNS. Improved cardiac output, reduced symptoms, reduced disease progression, and reduced sudden death are benefits of this therapy.

**DIURETICS.** Diuretics reduce fluid volume and decrease pulmonary venous pressure, which in turn decreases cardiac workload. Because they are given to help prevent edema, edema does not need to be present for their use. Diuretics act on various areas of the kidneys to promote the excretion of edema fluid. A combination of diuretics may be used to achieve the desired effect. Electrolytes (especially potassium levels to prevent hypokalemia) and fluid balance (to prevent dehydration) should be carefully monitored during therapy. Potassium supplements are often given with potassium-wasting diuretics.

**ALDOSTERONE ANTAGONISTS.** Spironolactone (Aldactone) blocks the effects of aldosterone, which causes the retention of sodium and fluid. Potassium must be monitored carefully because spironolactone is a potassium-sparing agent and the risk of hyperkalemia increases if ACE inhibitors or ARBs are also used.

**BE SAFE!** Always check potassium levels before giving a potassium-wasting diuretic such as the loop diuretics furosemide (Lasix), bumetanide (Bumex), or torsemide (Demadex) or before giving a potassium supplement, which the patient may be taking due to diuretic therapy. Do not give a diuretic if the potassium level is low or a potassium supplement if the potassium level is high.

**INOTROPIC AGENTS.** Inotropic drugs strengthen ventricular contraction to increase cardiac output. Inotropic agents include digitalis (digoxin), sympathomimetics (dobutamine), and phosphodiesterase inhibitors (milrinone). The sympathomimetics and phosphodiesterase inhibitors are usually used short term.

**Digitalis.** In addition to improving contraction strength, digitalis preparations decrease conduction time within the heart,
which slows the heart rate to allow more complete emptying of the ventricles. Obtaining an apical pulse rate before administration of digitalis is required. Digitalis may increase myocardial oxygen needs, so it is used cautiously. Monitoring of serum drug levels is necessary to detect toxic levels of the drug. If toxic levels are present, the drug is stopped to allow digitalis levels to decrease over time.

CRITICAL THINKING

Mr. Shepard—Part 3

During Mr. Shepard’s visit, the HCP tells him to continue the ACE inhibitor, the diuretic, and a 2-g sodium diet.

1. Why is the ACE inhibitor continued?
2. Will the ACE inhibitor affect preload or afterload?
3. Why is the diuretic ordered?
4. What lab test result is checked before administering diuretics?
5. Why is a 2-g sodium diet ordered?
6. What is the overall goal of the ordered treatment?

Suggested answers are at the end of the chapter.

Pacemakers and Implantable Cardioverter Defibrillator

For patients at risk of sudden death, pacemakers and implantable cardioverter defibrillators (ICDs) are used along with medication therapy. They can pace the heart rate and rhythm or deliver an electric countershock if a life-threatening rhythm occurs.

Cardiac Resynchronization Therapy

With HF, the ventricles do not always beat in normal synchrony with each other. This dyssynchrony results in less effective pumping by the ventricles and reduced stroke volume. Cardiac resynchronization therapy (CRT) restores normal contraction timing of the ventricles. It reduces symptoms and improves quality of life. A biventricular cardiac pacing system is used. An atrial lead senses or paces the atria as needed. A right and left ventricular lead stimulates the ventricles to synchronize their contractions in response to the atrial event. Left ventricular filling and thus contraction is then improved. CRT therapy is also available with an implantable cardioverter defibrillator (CRT-D). For more information and pictures of CRT devices, visit www.medtronic.com.

Mechanical Assistive Devices

Mechanical assistive devices can provide temporary support to patients in cardiogenic shock and act as a bridge to transplantation, destination therapy (long-term solution when other options are not available for the failing heart), or heart replacement. These devices increase the cardiac output of the patient. They include the intra-aortic balloon pump, ventricular assist devices, total artificial heart, and implantable replacement heart. Technology in this area is continually changing. For current information and to see pictures of these devices, see DavisPlus.

INTRA-AORTIC BALLOON PUMP. For acute care, an intra-aortic balloon pump (IABP) increases circulation to the coronary arteries and reduces the work of the heart. The IABP catheter is inserted into the femoral artery and positioned in the descending aortic arch (Fig. 26.3). It is attached to a computer that senses ventricular contraction and controls the balloon. While the heart is relaxed (diastole), the balloon is inflated, sending more blood into the coronary arteries. Just before the heart contracts (systole), the balloon deflates to allow blood to flow past it. The deflation of the balloon creates a suction effect, which allows the blood to flow past it with less resistance (decreased afterload) into the aorta. The IABP is inserted in a cardiac catheterization laboratory, critical care unit, or surgical suite and is used short term for several days.

VENTRICULAR ASSIST DEVICES. Ventricular assist devices (VADs) are implanted mechanical devices that assist cardiac pumping (Fig. 26.4). These devices maintain cardiac output and allow the failing ventricle to rest. VADs are used temporarily as a bridge to transplantation (while awaiting a donor heart), bridge to recovery (for hearts that potentially can recover), or as destination therapy (long-term therapy) for those who are not candidates for heart transplant. They may also be referred to as left ventricular assist devices (LVADs) if used in the left ventricle only, right ventricular assist devices (RVADs) if used in the right ventricle only, or bi-VADs for simultaneous use in both the left and right ventricles.
Surgical Management

HF causes may be treated surgically with coronary artery bypass for coronary artery disease or valve replacement for valvular disease (see Chapters 23 and 24). Once these conditions are treated, HF symptoms should resolve.

Surgical ventricular reconstruction (SVR) reduces left ventricular volume in HF patients. It is often done along with coronary artery bypass surgery. The STICH trial data on further analysis showed that coronary artery bypass graft (CABG) with SVR increased survival when certain parameters occurred (end systolic volume index 70 mL/m² or less; Michler et al, 2013).

Nursing Process for the Patient With Chronic Heart Failure

Data Collection

While obtaining data for the patient with HF, focus on areas that might indicate the presence of HF (Table 26.6).

Nursing Diagnoses, Planning, Interventions, and Evaluation

See the “Nursing Care Plan for the Patient With Chronic HF” for common nursing diagnoses. The major focus of nursing care for chronic HF patients is to improve oxygenation and decrease the body’s need for oxygen with rest, positioning, medications, fluid balance, and oxygen consumption control.

Continued
OXYGEN. Oxygen therapy is ordered by the HCP and guided by blood gas analysis and patient symptoms. Before starting oxygen therapy, explain the therapy to the patient. For chronic HF, oxygen is administered at 2 to 6 L/min via nasal cannula. The effects of the oxygen should be monitored carefully.

REST AND ACTIVITY. Reduction of the body’s oxygen demands decreases the workload of the heart. A balance of rest and activity that does not produce signs or symptoms of oxygen deprivation is essential. The activity level of the patient is determined by the severity of the HF. During times of exertion, monitor the patient’s vital signs and respiratory effort for oxygen deprivation. If activity intolerance develops, the activity should be stopped.

POSITIONING. Semi-Fowler’s or high-Fowler’s position makes breathing easier. In upright positions, the lungs are able to expand more fully and gravity decreases the amount of fluid returned to the heart, thereby reducing the heart’s workload.

FLUID RETENTION. Monitoring daily weights for weight gain is important in detecting fluid retention. Edema is usually not observed until 5 to 10 pounds of extra fluid are present. A baseline weight should be obtained when HF is diagnosed. Daily weights should be measured on the same scale, at the same time of day, and with the same type of clothing worn to ensure accuracy. A good time to obtain a daily weight is in the morning after the bladder is emptied. Documentation of daily weights should include the date and time of the weight, the scale used, the clothing worn, and the weight measurement. The patient can keep a weight journal. Tell patients to report weight gains of 2 to 3 pounds over 1 to 2 days.

### NURSING CARE PLAN for the Patient With Chronic Heart Failure

**Nursing Diagnosis:** Activity Intolerance related to fatigue caused by oxygen imbalance

**Expected Outcome:** The patient will show increased activity tolerance with vital signs within normal limits (WNL) in response to activity.

**Evaluation of Outcome:** Does the patient participate in activities and maintain vital signs WNL?

**Intervention**
- Provide rest, space activities, and conserve energy. **Rationale** Myocardial oxygen need is decreased with rest and energy conservation. **Evaluation** Does patient participate in activity with minimal pulse rate or ECG changes?

**Intervention**
- Assist as needed with activities of daily living (ADLs). **Rationale** Conserve energy by assisting with ADLs. **Evaluation** Are patient’s ADLs met?
NURSING CARE PLAN for the Patient With Chronic Heart Failure—cont’d

**Intervention** Teach use of assistive devices and lifestyle changes. **Rationale** Assistive devices can overcome limitations to increase activity. **Evaluation** Does patient incorporate assistive devices into lifestyle changes?

**GERIATRIC**

**Intervention** Increase time allowed to complete activities. **Rationale** Independence and participation are increased if extra time is allowed for tasks. **Evaluation** Does patient report greater ability to complete activities with fewer symptoms?

**Nursing Diagnosis:** *Excess Fluid Volume* related to HF and the secondary reduction in renal blood flow for filtration

**Expected Outcomes:** The patient will remain free from edema and dyspnea, have clear lung sounds, and maintain baseline weight at all times.

**Evaluation of Outcomes:** Does patient have clear lung sounds with baseline weight maintained?

**Intervention** Monitor for edema, weight gain, jugular venous distention (JVD), lung crackles. **Rationale** Excess fluid is indicated by edema, sudden weight gain, JVD, and crackles in the lungs. **Evaluation** Are edema, weight gain, JVD, or crackles present? Are they worsening or improving?

**Intervention** Monitor intake and output (I&O). **Rationale** I&O will show imbalances. **Evaluation** Are I&O balanced for 24 hours?

**Intervention** Administer diuretics. **Rationale** Diuretics promote fluid excretion. **Evaluation** Is output increased and edema or dyspnea reduced?

**Intervention** Decrease sodium intake as ordered. **Rationale** Sodium retains fluid. **Evaluation** Does patient restrict sodium intake?

**Intervention** Maintain fluid restriction as ordered. **Rationale** Excess fluid intake contributes to edema. **Evaluation** Does patient restrict fluid intake?

**Nursing Diagnosis:** *Disturbed Sleep Pattern* related to nocturia and inability to lie down and sleep comfortably

**Expected Outcome:** The patient will awaken refreshed and be less fatigued during the day at all times.

**Evaluation of Outcome:** Does patient wake up less frequently during the night and feel more refreshed with less fatigue during the day?

**Intervention** Identify barriers to sleep. **Rationale** Anxiety, nocturia, diuretics, orthopnea, or paroxysmal nocturnal dyspnea can make sleep difficult. **Evaluation** Does patient identify sleep barriers?

**Intervention** Assist patient in identifying positions of comfort for sleeping. **Rationale** Use of pillows or a recliner can decrease orthopnea. **Evaluation** Can patient identify a position of comfort?

**Intervention** Teach patient cause of dyspnea at night. **Rationale** Anxiety about falling asleep and waking up short of breath is reduced. **Evaluation** Can patient explain cause of dyspnea?

**Intervention** Encourage patient to recline for 30 to 60 minutes before bedtime. **Rationale** Reclining before bedtime redistributes fluid to the kidneys so that the patient can void before going to sleep instead of soon afterward. **Evaluation** Is patient awakened to void after going to bed less often?

**GERIATRIC**

**Intervention** Encourage patient to take diuretics according to sleep patterns. If sleeps during nighttime hours, then take diuretic early in the day. If sleeps during daytime hours, then take medications after rising. **Rationale** Nocturia is reduced if diuretics are taken earlier in the day. **Evaluation** Does patient take diuretics early and report less nocturia?
OXYGEN CONSUMPTION. Increased oxygen consumption by the heart should be avoided. Sustained tachycardia increases the oxygen needs of the heart and should be reported promptly to the HCP for treatment. Older patients are especially vulnerable to the effects of tachycardia because of their decreased reserves. Constipation should be prevented because straining during defecation, known as the Valsalva maneuver, increases the heart’s workload by increasing venous return to the heart. Stool softeners should be administered, as ordered, to prevent straining.

Patients should be taught methods of saving energy while performing ADLs. Fatigue should be avoided by alternating activity with periods of rest. A referral to occupational therapy and physical therapy can be helpful for developing techniques that allow the patient to conserve energy during self-care. Some suggestions for conserving energy include placing frequently used objects at waist level to avoid reaching overhead, planning bathing activities to include rest periods, and using Velcro fasteners to make dressing easier.

MEDICATIONS. HF is a progressive, chronic condition, and patients may require lifetime medication. Combination drug therapy is often needed, and taking multiple pills daily can be challenging. Financial resources, adherence to therapy regimen, and ongoing monitoring are issues that must be considered.

Diuretics. Diuretics require monitoring of the patient’s potassium levels and blood pressure. To prevent hypokalemia, potassium supplements may be prescribed during diuretic therapy, and a diet with high-potassium foods is encouraged. If too much fluid is removed, the patient may become hypotensive, and orthostatic hypotension can develop. The patient may then become dizzy and at risk of falling. Caution the patient to change positions and rise slowly to prevent falls during diuretic therapy.

Digitalis. Before administration of a digitalis drug, which slows the heart rate, the patient’s apical pulse should be counted for 1 minute. If the pulse is below 60 beats/min, notify the HCP to determine if the drug should be given. Some patients are given digitalis even if their heart rates are between 50 and 60 beats/min, as long as their heart’s conduction system is normal or if the rate is due to other medications such as a beta blocker. When giving digitalis, be aware that hypokalemia increases the heart’s sensitivity to digitalis. A patient can become toxic on a normal dose of digitalis when hypokalemia is present. This is important to note because many people on digitalis also take diuretics, which may lower potassium levels. Monitoring for signs and symptoms of digitalis toxicity should be done routinely during patient assessment. Early signs and symptoms of digitalis toxicity are anorexia, nausea, and vomiting; bradycardia or other dysrhythmias; visual problems; and mental changes. Older adults are especially prone to the toxic effects of this drug and may exhibit confusion when levels are toxic.

Vasodilators. Medications with vasodilating effects reduce the heart’s workload by decreasing vascular pressure. Blood pressure is monitored when administering vasodilators.

Medication Teaching. Patients and their families are taught the purpose, side effects, and precautions for prescribed medications. Patients should understand the importance of taking their medication as prescribed, even if they do not have symptoms. A schedule should be developed so patients remember to take their medications. Teach them to report side effects to the HCP. If dizziness occurs from drugs that reduce blood pressure, the drugs can be staggered so that the y are not all taken at the same time. Patients taking digitalis or a beta blocker should be taught to take their pulse and to notify their HCP if it is below 60 beats/min or below the lower limit heart rate set by their HCP. Patients on diuretics should be taught the following:

• Take drug during the day before 1600 to decrease being awakened at night to void (if desired).
• Have a readily available and obstacle-free bathroom or commode to prevent incontinence and falls.
• Eat high-potassium foods if taking a potassium-wasting diuretic.
• Weigh oneself daily, and report weight gains of 2 to 3 pounds over 1 to 2 days.

LOW-SODIUM DIET AND WEIGHT CONTROL. A dietitian consult helps the patient and family understand the need for adherence to a special diet and ways to provide menus that are appealing and easy to use. Eating should remain pleasurable for the patient to avoid malnutrition. Discuss foods the patient likes and can still have rather than talking about only foods they cannot have. Patients are taught to read food labels to determine which foods are high and low in sodium content. They are also taught that salt substitutes may contain potassium. With this knowledge, patients can help design a daily meal plan using low-sodium foods that are appealing to them. Food preparers are taught not to salt food during cooking, and table salt should be eliminated. Spices, herbs, and lemon juice may be suggested to flavor unsalted foods.

For overweight patients, weight reduction may help eliminate the underlying cause of HF. Diet counseling and support should be given to the obese patient to encourage weight loss. The body mass index (BMI) and waist-to-hip ratio should guide weight loss. If anorexia occurs in the later stages of HF, the patient’s intake should be evaluated. Several small meals rather than three large meals will decrease the heart’s workload. If the patient’s nutritional needs are not being met, the HCP should be informed for a referral to a dietitian.

EDUCATION. Chronic management of HF requires patient and family understanding of the disease process, management of home oxygen therapy, diet and weight control, need for immunizations such as the annual flu shot, and medications (see “Home Health Hints”). The patient and family must recognize the importance of each of these factors to foster quality of life for the patient with chronic HF. A discussion of HF and signs and symptoms to report to the HCP using simple terms should be included in the teaching plan (Box 26-1, “Patient and Family Education”).
Box 26-1 Patient and Family Education

HF Signs and Symptoms to Report to the Health Care Practitioner

- Shortness of breath
- Fatigue
- Dry cough
- Shortness of breath when lying down (orthopnea)
- Episodes of sudden awakening with shortness of breath (paroxysmal nocturnal dyspnea)
- Weight gain of 2 to 3 pounds over 1 to 2 days
- Ankle or foot edema
- Nocturia
- Anorexia

Home Health Hints

- Some patients may not have a scale in their home. It may be necessary to assist them in obtaining one or to leave an agency scale in the home for daily weights.
- The most objective way to document edema is to use a tape measure (marked in centimeters) on the abdominal girth, thigh, calf, and ankle. Measure at the same place each visit, such as measuring the girth of the calf at a specified distance above the medial malleolus. Edema may be present if the patient’s waistband is getting tighter or shoes and socks feel tighter.
- The sacrum, back, and sides of a bedridden patient should be checked to note edema. These are dependent areas in the bedridden patient, so fluid accumulates in these areas instead of the ankles.
- Blood drawn for potassium levels needs to be transported to the laboratory within 1 hour. Ice should not be put directly on the blood-draw tube because this can cause destruction of the cells and a false elevation in the potassium level.
- Blood drawn for digoxin (Lanoxin) levels should be taken to the lab within 2 to 3 hours.
- Patients who are on sodium-restricted diets should use no-salt-added canned vegetables. If canned vegetables are not low-sodium, patients should be instructed to pour off the liquid and rinse the vegetables before heating them for serving. The use of herbs and spices can help make them more flavorful.
- For the patient on a low-sodium diet, an effective diet teaching technique is to have the patient name the foods highest in sodium. Asking the patient to rename the list on each visit helps knowledge retention and adherence to the diet.
- If patients have a poor appetite, ask their caregiver if they eat well when eating with others. Anorexia could be a sign of loneliness and depression if they eat well with others instead of an effect of HF.
- Assist patients in taking medications at times that fit their lifestyle. A morning dose of a diuretic may limit what they can do for the next few hours. An afternoon dose might encourage adherence to the medication regimen. Lack of adherence is a major factor in the rehospitalization of patients with HF. A dose of diuretic too late in the day may cause frequent awakenings during the night to void.
- The home health nurse should periodically check the contents of medicine bottles. If pills have been cut in half, question the patient because this is often an attempt by the patient to “stretch” the medicine to decrease expenses. Find out about community or drug company programs that help purchase medicines for patients with financial need. Eligible Medicaid patients can apply for medication cards. The new Medicare Part D prescription program, as well as retail drug discount programs, may be helpful as well.
- Visual disturbances can occur from digitalis toxicity. If the patient sees halos around lights or red-green tinting on everything, report this to the HCP.
- Troublesome side effects of an ACE inhibitor such as captopril (Capoten) are an intractable cough and hypotension. Note if the patient is coughing. Teach the patient to report the cough.
- Oxygen concentrators are widely used in home care. Instructions must be given on the proper use of the oxygen and safety precautions for oxygen use. Long tubing allows the patient ease in moving about the home. Patients need to be cautioned about keeping the tubing out of their way and not kinking it. Patients and caregivers should also be cautioned as to the explosive nature of oxygen and the danger of smoking in its presence.
- As the home health nurse becomes acquainted with the patient, it is easier to pick up on signs of oxygen deprivation and hypoxia, such as confusion, combativeness, or unusual expressions of anger.
- For patients with orthopnea, a foam wedge can be obtained from a medical equipment company to use under their head when sleeping instead of pillows.
- As patients with HF feel better, they may go back to the old habits that cause an increase in fluid. The home health nurse can help by providing information about the disease and help patients foster their own independence and ways of coping with the condition. Each home health visit is a teaching opportunity that empowers patients with a knowledge base to help them take control of their health.
COPING. Living with a chronic illness can be frustrating for both patients and their families. An assessment of coping skills used by patients and their families can be used to develop a plan for coping with this current illness. Available support systems are explained to patients. Referrals to social workers, sexual counselors, and nurse-managed clinics can be helpful in providing resources that may make living with HF easier. Providing patients options for traveling can help maintain quality of life.

Understanding the chronic nature of HF is important for patients, families, and caregivers so they can positively deal with the emotions and feelings that can result. Nurse-managed HF clinics have been shown to decrease hospitalization rates and increase effective management of the therapeutic regimen.

Should the patient’s condition worsen irreversibly, a discussion regarding the possibility of organ donation could be considered. Such a discussion would require a team approach involving other members of the health care team (physician, social worker, clergy). As of 2013, 18 people will die each day waiting for an organ, yet one donation can save up to eight lives. For more information, visit www.organdonor.gov.

CARDIAC TRANSPLANTATION

Cardiac transplantation is reserved for patients with end-stage cardiac disease. Guidelines for the selection of recipients and donors are applied to optimize survival (Box 26-2). Preoperative teaching is done once the recipient is accepted into the transplant program. For more information on heart transplantation, visit www.nhlbi.nih.gov/health/dci/Diseases/ht/ht_whatis.html.

To increase the availability of organs for transplant, a device has been developed that keeps the heart beating and nourished with the donor’s blood during transport for up to 12 hours. The device, Organ Care Systems (Heart in a Box) is in use in Europe and in trials in the United States.

Surgical Procedure

Once a donor heart is found, the recipient is notified, admitted to the hospital, and prepared for surgery. The general procedures for this surgery are similar to those described in Chapter 21. Two types of cardiac transplant procedures are performed: orthotopic and heterotopic. In the orthotopic procedure, once the patient is on cardiopulmonary bypass (CPB), the recipient’s diseased heart is removed, leaving the posterior wall of the atria, superior and inferior vena cava, and pulmonary vein (Fig. 26.5). The aorta and pulmonary artery are cut. The donor’s atria, aorta, and pulmonary artery are then anastomosed to the recipient’s atria, aorta, and pulmonary artery. The heterotopic procedure joins the donor heart and vessels to the recipient’s heart and vessels without removing the recipient’s heart. The donor heart rests in the right side of the chest.

Immunosuppressive therapy is required to prevent rejection of the transplanted heart. Medications such as cyclosporine
(Neoral, Sandimmune), mycophenolate mofetil (CellCept), tacrolimus (Prograf), sirolimus (Rapamune), and Prednisone are used (“Nutrition Notes”). It begins preoperatively with high loading doses of these medications. The risk for rejection is highest immediately after surgery and decreases with time but never goes away, so doses of immunosuppressive medication are also highest initially after surgery and decrease with time. Lifelong antirejection therapy is required and often involves the combination of three drugs to allow lower doses to help reduce side effects.

**NUTRITION NOTES**

Cyclosporine, an immunosuppressant used to prevent transplant rejection, is metabolized by intestinal CYP3A4. Taking cyclosporine with grapefruit juice may cause elevated blood levels of the drug. In addition, St. John’s wort, sold as a dietary supplement, has interacted with cyclosporine (through both CYP3A4 and P-glycoprotein mechanisms) sufficiently to cause organ rejection.

**Complications**

Heart transplantation complications may include those associated with cardiac surgery, as well as heart rejection, which is the major cause of death within the first year. To detect rejection, frequent biopsies of cardiac muscle or a newer blood test to detect activation of rejection genesis is done during the first year. If a biopsy shows damaged cells, indicating rejection, antirejection drug therapy may be changed.

In addition, as a result of immunosuppressive therapy, infection and cancer may occur. The medications used for immunosuppressive therapy also may cause adverse reactions such as increased cholesterol, diabetes, kidney disease, cataracts, or osteoporosis.

**Therapeutic Measures**

After CPB is stopped, the patient receives a diuretic to aid in excretion of excessive circulating fluid. Intake and output are monitored hourly, and the patient is observed for fluid overload. Lung sounds are monitored frequently for crackles, and weight and electrolyte levels are checked daily.
Postcardiotomy syndrome may occur from days 2 to 5 after surgery and last a few weeks. Patients may arouse normally and be oriented but exhibit mild confusion or psychosis. Pupillary reaction and motor response are assessed. The safety of the patient is maintained with side rails up, bed in low position, and nursing call light within reach. The patient is given as much rest and as little sensory stimulation as possible. The family is kept informed and involved in the patient’s recovery.

Sleeping is difficult because of postoperative pain and the continuous level of activity in the ICU. Sleep is promoted in 90-minute intervals by dimming lights and decreasing all sensory stimulation near the patient. Additionally, listening to a favorite soothing type of music with earphones or the use of ordered narcotics for pain may also help sedate and relax the patient to allow for healing.

Temperature is monitored every 4 hours and complete blood cell count (CBC) and white blood cell (WBC) results are monitored for indications of infection. If oral thrush (white patches) develops, an antifungal agent is ordered. A urine culture to diagnose a urinary tract infection is ordered if cloudy urine or urinary tract burning occurs.

Nursing Process for the Preoperative Cardiac Transplant Patient

General preoperative and postoperative surgical care is discussed in Chapter 12. Postoperative needs for the patient undergoing cardiac surgery are discussed next.

Nursing Process for the Postoperative Cardiac Transplant Patient

Data Collection

The patient is accompanied to the ICU by the anesthesiologist, who gives the nurse a report of the procedure, complications, and hemodynamic and ventilatory management of the patient. The patient is connected to a cardiac monitor and a mechanical ventilator for 4 to 24 hours. A temporary pacemaker is connected to the epicardial pacing wires if they were placed during surgery as a precaution to treat bradycardia and other dysrhythmias. The patient is placed under a forced-air warming device, such as a blanket. The chest tubes are monitored, the nasogastric tube is placed to suction, and the urinary catheter is placed for gravity drainage.

A head-to-toe assessment of the patient, including dressings, tubes, and IV lines, is performed. Of importance are signs of awakening, shivering, pain, lung, and heart sounds, and palpation of the entire chest and neck to detect crepitus (air in the subcutaneous tissue from opening the chest). CBC, electrolytes, coagulation studies, and ABGs are monitored.

Cardiac transplant patients may be in isolation for their own protection, depending on the agency’s policy.

After the initial transfer assessment, vital signs, oxygen saturation, and cardiac pressures are monitored and recorded every 15 to 30 minutes, with decreasing frequency as the patient stabilizes. Input and output (I&O) is measured and vital signs are monitored. An ECG is done to detect perioperative MI. A chest x-ray examination is done to check central line and endotracheal tube placement and to detect a pneumothorax or hemothorax, diaphragm elevation, or mediastinal widening from bleeding. At this point, the family may see the patient, and patient care is explained.

Nursing Diagnoses, Planning, Implementation, and Evaluation

Nursing diagnoses for postoperative cardiac surgery or transplant are discussed in the “Nursing Care Plan for the Postoperative Patient Undergoing Cardiac or Transplant Surgery.”

Coping With Cardiac Transplant

Cardiac transplant patients may have feelings of sadness and grief for the donor and his family while also experiencing great elation, relief, and hope after a long wait for the transplant. Patients should be told that these feelings are normal and should be allowed to express their feelings when they are ready. Emotional support may be needed.

Transplant rejection is a possible complication of this surgery. Patients need to understand the importance of following instructions regarding medications and testing that are related to preventing or detecting rejection.

Cardiac transplant patients are followed in an exercise rehabilitation program that closely monitors their activity progression in relation to myocardial oxygen consumption and signs of activity intolerance. Most patients reach an activity level allowing them to participate in many recreational sports.
NURSING CARE PLAN for the Postoperative Patient Undergoing Cardiac or Transplant Surgery—cont’d

**Intervention** Obtain characteristics of pain with each episode. **Rationale** A thorough description is needed to determine cause and plan actions. **Evaluation** Does patient describe pain on scale of 0 to 10?

**Intervention** Splint chest incision with all movement and coughing and deep breathing. **Rationale** Stabilizes sternum and incision to increase comfort. **Evaluation** Can patient splint chest incision independently?

**Intervention** Encourage patient to report pain even when pain is mild. **Rationale** It is easier to keep pain under control when mild. **Evaluation** Does patient report pain when mild?

**Intervention** Turn, reposition every 2 hours. **Rationale** Changes muscle position, relieving stiffness. **Evaluation** Is patient comfortable without stiffness?

**Intervention** Offer back rubs frequently. **Rationale** Relaxes tense muscles retracted during operation. **Evaluation** Is patient able to rest in comfort?

**Intervention** Instruct patient to take a deep breath before movement and exhale slowly during movement. **Rationale** Keeps muscles relaxed, minimizing tension with guarding and pain. **Evaluation** Can patient perform coughing and deep-breathing techniques as instructed?

**Intervention** Explain that chest pain can occur from the surgical incision rather than the heart. **Rationale** Chest pain after surgery can be frightening for patients because they may not associate surgical chest pain with the incision and instead think the pain is anginal or infarction pain. **Evaluation** Does patient state understanding of pain sources?

**Nursing Diagnosis:** Decreased Cardiac Output related to myocardial depression, hypothermia, bleeding, unstable dysrhythmias, or hypoxemia

**Expected Outcomes:** The patient will remain free of major side effects of pharmacological support. The patient will maintain vital signs within normal limits (WNL), palpable peripheral pulses, urine output greater than 0.5 to 1 mL/kg/hr, and normal sinus rhythm posttransplant.

**Evaluation of Outcomes:** Is patient free of major side effects? Are vital signs WNL?

**Intervention** Monitor vital signs. **Rationale** Trends reflect problems. **Evaluation** Are vital signs WNL?

**Intervention** Monitor peripheral circulation. **Rationale** Mottling or weak pulses may indicate poor cardiac output (CO). **Evaluation** Do peripheral pulses remain strong with normal skin color, temperature, capillary refill?

**Intervention** Monitor I&O. **Rationale** Fluid deficit or excess can alter CO. **Evaluation** Does total intake equal output?

**Intervention** Listen to lung sounds and note character of sputum. **Rationale** Crackles may indicate HF or pulmonary edema. **Evaluation** Are lungs clear?

**Intervention** Monitor temperature closely while rewarming the patient. **Rationale** Febrile state increases heart rate and myocardial oxygen consumption. **Evaluation** Does temperature remain less than or equal to 98.6°F (37°C)?

**Intervention** Monitor chest tube drainage for increase or sudden decrease. **Rationale** Drainage = 200 mL/hr may lead to hypovolemia and a decrease in CO. **Evaluation** Is patient free from cardiac tamponade and hypovolemia?

**Intervention** Monitor ECG. **Rationale** Premature ventricular contractions and atrial fibrillation decrease CO. **Evaluation** Does patient remain in normal sinus rhythm or controlled dysrhythmia?

**Intervention** Monitor electrolytes. **Rationale** Low calcium and magnesium and high potassium decrease contractility and CO. **Evaluation** Are electrolytes WNL?
NURSING CARE PLAN for the Postoperative Patient Undergoing Cardiac or Transplant Surgery—cont’d

**Intervention** Monitor arterial blood gases (ABGs). **Rationale** Acidosis decreases heart function, and a low CO may lead to further acidosis. **Evaluation** Are ABGs WNL?

**Nursing Diagnosis:** Risk for Infection related to inadequate primary defenses from surgical wound or immunosuppression (transplants)

**Expected Outcome:** The patient will remain free from infection posttransplant.

**Evaluation of Outcome:** Does patient remain free from infection?

**Intervention** Monitor and report abnormal findings for temperature, lung sounds, sputum, and urine consistency. **Rationale** Low-grade (immunosuppressed) or high-grade fever, crackles, yellow-green sputum color, or cloudy urine can indicate infection. **Evaluation** Is the patient’s temperature WNL and are lung sounds, sputum, and urine clear?

**Intervention** Encourage coughing and deep breathing and incentive spirometer use. **Rationale** Lung infections can be prevented with lung expansion and secretion removal. **Evaluation** Does patient perform coughing and deep breathing and use incentive spirometer?

**Intervention** Observe incision for signs and symptoms of infection. **Rationale** Redness, warmth, fever, and swelling indicate infection. **Evaluation** Are signs and symptoms of infection present?

**Intervention** Monitor drainage and maintain drains. **Rationale** Drains remove fluid from the surgical site to prevent infection development. **Evaluation** Are drainage amount and color normal for procedure? Are drains functioning?

**Intervention** Maintain sterile technique for dressing changes. **Rationale** Sterile technique reduces infection development. **Evaluation** Is incision free of signs and symptoms of infection?

**Nursing Diagnosis:** Deficient Knowledge related to lack of prior experience with transplant

**Expected Outcome:** The patient will demonstrate understanding of posttransplant care before discharge.

**Evaluation of Outcome:** Does patient state understanding and ability to carry out posttransplant care?

**Intervention** Give information in small increments and use written and video materials. **Rationale** Cardiac transplant patients commonly have memory deficits, cognitive dysfunction, and short attention spans resulting from long-term decreased cerebral perfusion. **Evaluation** Does patient state understanding of information?

**Intervention** Include families in teaching sessions and encourage them to promote self-care by the patient. **Rationale** Family involvement in teaching sessions is important to promote understanding and retention. **Evaluation** Does family participate and state understanding of teaching sessions?

**Intervention** Address or refer sexual functioning questions with patients and their partners. **Rationale** Patients usually have questions regarding sexual functioning. Referrals can be made to sexual counselors. **Evaluation** Does patient state that questions have been addressed?

**Intervention** Discharge teaching includes treatment, complications, activity, medications, and enhancing quality of life. **Rationale** Patients need comprehensive information to comply with posttransplant care. **Evaluation** Does patient state understanding of discharge care?
Mrs. Eden

1. Signs and symptoms of HF include shortness of breath, two-pillow orthopnea, dry cough, tachycardia (pulse 106 beats/min), tachypnea (respiration 24 per minute), and bilateral crackles.

2. Left-sided HF is indicated by the findings.

3. Shortness of breath: fluid in the lungs impairs gas exchange; orthopnea: lying flat increases fluid accumulation in the lungs, causing dyspnea; dry cough: fluid in the lungs irritates the mucosal lining of the lungs; tachycardia: sympathetic compensation to increase cardiac output; tachypnea: sympathetic compensation to increase blood oxygenation; bilateral crackles: fluid trapped in the lungs.

4. The two pillows help prevent orthopnea by using a more upright position, which allows gravity to decrease fluid accumulation in the lungs.

5. HCP (physician, physician’s assistant, nurse practitioner), case manager, nurses, dietitian, physical therapist, occupational therapist, pharmacist, social worker, and clergy.

Mr. Shepard—Part 1

1. Signs and symptoms of HF include shortness of breath, two-pillow orthopnea, dry cough, tachycardia (pulse 106 beats/min), tachypnea (respiration 24 per minute), and bilateral crackles.

2. Left-sided HF is indicated by the findings.

3. Shortness of breath: fluid in the lungs impairs gas exchange; orthopnea: lying flat increases fluid accumulation in the lungs, causing dyspnea; dry cough: fluid in the lungs irritates the mucosal lining of the lungs; tachycardia: sympathetic compensation to increase cardiac output; tachypnea: sympathetic compensation to increase blood oxygenation; bilateral crackles: fluid trapped in the lungs.

4. The two pillows help prevent orthopnea by using a more upright position, which allows gravity to decrease fluid accumulation in the lungs.

5. HCP (physician, physician’s assistant, nurse practitioner), case manager, nurses, dietitian, physical therapist, occupational therapist, pharmacist, social worker, and clergy.

Mr. Shepard—Part 2

1. Mr. Shepard’s heart is enlarged to compensate for the strain caused by increased peripheral vascular resistance from hypertension to maintain an adequate cardiac output.

2. An enlarged heart requires more oxygen, which often cannot be supplied in HF.

Mr. Shepard—Part 3

1. The ACE inhibitor is needed for vasodilation to reduce peripheral vascular resistance and decrease the heart’s workload, which in turn prevents cardiac remodeling and improves functioning.

2. The ACE inhibitor will affect afterload.

3. The diuretic is ordered to decrease fluid volume, which reduces preload and decreases the heart’s workload.

4. Potassium needs to be monitored because diuretics can be either potassium wasting or potassium sparing.

5. The low-sodium diet is ordered to reduce water retention, which decreases preload and decreases the heart’s workload.

6. The goal is to decrease the heart’s workload and increase its efficiency by reducing preload and peripheral vascular resistance and to decrease progression of chronic HF and improve survival.

Mr. Shepard—Part 4

1. After assessment of Mr. Shepard’s knowledge base, medication teaching should be given on the ACE inhibitor and diuretic that includes their purpose, side effects, and precautions. A schedule for taking the medications can be planned. An explanation of the purpose of a low-sodium diet and menu planning based on Mr. Shepard’s likes and dislikes should be done.

2. Low-sodium foods should be selected to prevent fluid retention, and high-potassium foods should be included to prevent hypokalemia from the diuretic if appropriate. Read food labels. Low-sodium foods include puffed rice, wheat cereals, fruits, chicken, beef, eggs, and potatoes. High-sodium foods include tomato juice, sauerkraut, softened water, buttermilk, cheese, smoked meats, canned tuna, canned soup, pickles, instant rice, and instant potatoes. High-potassium foods include salt substitutes, bran products, avocado, bananas, prunes, oranges, baked potato, sweet potato, spinach (cooked), chocolate, nuts, and molasses.

Mrs. Eden

1. Is Mrs. Eden tolerating this activity? Why or why not?

2. List four reasons why Mrs. Eden has a poor appetite.

3. Give four patient-centered nursing interventions for Mrs. Eden’s poor appetite.

4. Give three reasons why Mrs. Eden is withdrawn.

5. What health care team members might collaborate in Mrs. Eden’s care?

Suggested answers are at the end of the chapter.
